ADDRESSES AND ORIGINAL ARTICLES

RINCIPLES OF X RAY THERAPY OF MALIGNANT DISEASES *

By Henri Coutard, M.D.

HEF OF THE DEPARTMENT OF X RAY THERAPY FOR CANCER, RADIUM INSTITUTE OF THE UNIVERSITY OF PARIS (FONDATION CURIE)

30/1

(WITH ILLUSTRATIVE PLATES)

HE discussion of the principles of X ray therapy ıalignant tumours will be divided into four parts :

;) Some results of sufficiently long standing to r that the cure of cancer by X ray therapy is ıible.

) The physical and clinical technique by means hich these results have been obtained.

) General biological principles.

) Present knowledge of X ray therapy of cancer.

Results of X Ray Therapy of Cancer

is certain that some cancers can be cured by ays, but the proportion of cures is at present er small and local and general accidents, early te, are not infrequent.

Tables I., II., and III. we reproduce the ts obtained by X ray treatment in some cases ally studied at the Fondation Curie.

Table I

phosarcoma of the mouth, tongue, and nasopharynx

s treated m 1920) 1926.	Survivals	
	after 5 years.	after 7 years.
45	8 (17%)	8 (17%)

lymphosarcoma, lymphatic metastases are generally ent, especially during the first years. The cured remained in good health, without metastases, for between 5 and 7 years.

Table II

Epithelioma of the tonsillar region

treated n 1920 1926.	Survivals	
	after 5 years.	after 7 years.
46	13 (28%)	8 (17%)

he 13 patients still alive five years after their treat- 5 died between the fifth and seventh year, 4 of them bdominal or thoracic metastases.

Table III

Epithelioma of the larynx

treated n 1920 1926.	Survivals	
	after 5 years.	After 7 years.
77	22 (28%)	21 (27%)

22 patients who survived five years, only one died en the fifth and seventh year from a local recurrence.

have to keep in mind that the proportion of is not so high every year ; in some years the er increases, in others it drops. For instance, pitheliomas of the tonsil and soft palate the 1925 was a bad one. Out of 13 patients treated, one patient is alive five years afterwards—i.e., r cent. For epithelioma of the larynx the 1922 was a bad one. Of 11 patients treated, not as alive after three years ; in the previous year however (1921) out of eight patients treated, four were still living when inquiry was made at the end of 1933—i.e., about 12 years after treatment.

In the larynx, more than in any other site, some cancers are easy and some very difficult to treat. X ray therapy of cancer of the larynx is relatively easy when the growth has only slightly immobilised the muscle and not yet invaded the cartilage. In these cases there are few failures and few accidents. The cutaneous dose necessary for the healing of these cancers is small, on an average 6000 r (on the skin), with fields of 50 sq. cm. and a duration of 15–25 days.

X ray treatment of radioresistant *cancers of the larynx*, which have immobilised the hemi-larynx, infiltrated the muscle, and invaded the cartilage, is generally difficult. In spite of heavy doses these cases are not often cured and accidents may occur. Doses of 7000 to 8000 r or more are required and often constitute the maximum supported by the tissues. This is a great difficulty which may be made less serious by a better distribution of the energy in the time. Nevertheless, X ray therapy being still in its infancy, it must, in radioresistant cancers, frequently yield to surgery or be combined with surgery ; for we must not forget that, in laryngeal cancers for instance, while X rays may be applied without danger to a recurrence following surgical operation, surgical intervention after X ray application is often dangerous.

The treatment of *cancer of the uterus* has given, at the Fondation Curie, results generally superior to those mentioned above, but X rays have rarely been applied alone. There has been nearly always an association of X rays and radium.

Cancer of the breast appears to be influenced most favourably by X rays, but our results do not cover a sufficiently long period to be reproduced here. The time needed for collecting control statistics of cancer of the breast is necessarily very long, since many cases are of slow evolution.

TWO ILLUSTRATIVE CASES

In order to give some idea of the appearance and extent of the lesions of the larynx and pharynx which X ray therapy is capable of causing to disappear, we reproduce radiograms, taken before and after treatment, of two extensive and certainly inoperable cancers.

The first case is that of an epithelioma of the larynx.

Fig. I., with explanatory diagram, shows a lesion which has invaded the whole of the larynx, from the hyoid bone to the inferior border of the cricoid. The transparent laryngeal space has disappeared at the level of the thyroid cartilage, the cricoid and the crico-thyroid space. The thyroid cartilage is partly destroyed. The pre-epiglottic space is invaded so that the thyroid portion of the epiglottis is forced backwards. The cricoid is pushed forwards, indicating an invasion of the pharynx through the spread of the neoplasm beyond the larynx. Clinically there was complete immobility of both halves of the larynx and a tracheotomy had to be performed.

Fig. II., taken one month later, shows considerable reduction of the lesion : the epiglottis has returned to its normal position. The laryngeal transparency is beginning to reappear and the transparent area of the ventricle of Morgagni is particularly noticeable.

Fig. III., with explanatory drawing, shows, a year later, the return of the larynx to its normal state. It has been possible to remove the tracheotomy tube ; the transparent laryngeal space is normal, and the epiglottis, thyroid, and cricoid cartilages have regained their usual appearance. The patient is at present in good health.

---

* livered at the Rooms of the Medical Society of London . 15th, 1934, on the occasion of the opening ceremony X ray department of the Marie Curie Hospital.

4

5784

The second case is that of an epithelioma of the hypopharynx.

Fig. IV. shows a lesion of the hypopharynx, extending from the entrance of the œsophagus below, that is to say, the inferior border of the cricoid, up to 2 cm. above the angle of the mandible, an estimated length of 7 to 8 cm. The hyoid bone, the cricoid cartilage, and the thyroid are pushed forward from the vertebral bodies by the neoplastic mass.

Fig. V. shows the return to the normal state one year and three months later. The tumour has disappeared; the hyoid bone, the thyroid, and the cricoid are again in contact with the vertebral bodies. This patient, after remaining cured locally, died six years later from pulmonary metastases.

Physical and Clinical Technique

Factors to be considered include tension, filtration, focal distances, fields, and dosage.

The results recorded above have been obtained under the following conditions:—

With a maximum tension of 190 to 200 kilovolts we have used 2 mm. of zinc and 3 mm. of aluminium, covered by 3 cm. of wood. The focal distances have been 50 to 60 cm. for lesions of the head and neck. For deeply situated lesions, such as cancer of the uterus, the focal distances have been 80 to 100 cm.

The quantity of energy, or dose delivered, has been measured on the skin and calculated in international r units.

The number of fields or ports of entry, their shape and size, have, of course, varied according to the extent of the lesion, its depth, and the glandular spread. In general, in dangerous zones—i.e., the head and neck—the area of the fields has been from 50 to 100 square cm., with alternating cutaneous doses which have been able to reach as a maximum in some cases 700 and even 800 r per day, during one, two, or three days; sometimes a dosage of only 200 to 300 r per day has been used, or even less. In tolerant zones, such as the subumbilical abdomen, the area of the fields has been on an average 250 to 300 square cm., with alternating cutaneous doses not exceeding 500 r per day.

Among the epithelial cancers which we have treated, those which have definitely disappeared have had depth doses ranging from 3000 to 4000 r for the radiosensitive, non-infiltrating forms and doses a little higher for the radioresistant forms. These figures correspond approximately to the doses received by the most deeply situated parts of the neoplastic lesion.

TECHNIQUE

The technical part of the treatment has thus consisted in delivering to the deepest parts of the neoplastic lesion the quantity of energy considered expedient. The total cutaneous dose has necessarily had to be much higher than the cancericidal dose or depth dose when the distance from cancer to skin was great and when the fields were small. The total cutaneous dose may be relatively little different from the depth dose if the fields are large and the distance from cancer to skin is small. Thus it happened that the total cutaneous doses in the cases of cancer of the larynx in thin subjects were only 50 per cent. greater than the dose which would produce disappearance of the cancer, while in cancer of the uterus they were in certain cases, in spite of the use of large fields, four times greater than the cancericidal depth dose; the utilisation of six to eight fields or more was thus unavoidable. The use of numerous fields has given rise to research in Germany on the depth dose as compared with the surface doses; these researches have been carried out with remarkable precision by means of calculation and the phantom.

Most of the sites which we have systematically treated have been chosen from among those whic it was possible to observe clinically each day. W have always preferred to rely on a daily examinatio of the patient rather than in a knowledge of th depth dose. This examination involves daily verification of changes in the appearance of the neoplasm, o the vasculo-connective tissue and of the mucous membranes adjoining the neoplasm; observation of th glandular secretions; and a note of the genera reaction of the organism. Indeed, as we shall see late on, while the dose is an element of the X ray therap of cancer (though an element very difficult to determine in advance), the biological conditions unde which this dose must be distributed are sometimes mor important, the exception being in the case of the ver small, superficial, and very radiosensitive cancers.

VASCULO-CONNECTIVE TISSUE AND GLANDULAR RADIOREACTIONS

The most prominent and most evident vasculo-connective tissue radioreactions are the early œdema, the erythema of the skin, and the local congestion of the mucous membranes. Sometimes they develop in a progressive manner and in this case they may not be too harmful. Sometimes they appear abruptly in the course of treatment when the dose or the intensity has been increased too much; in this case they are as incompatible with the involution of the cancer as with the conservation of the medium in which the cancer is growing.

The œdema, erythema, and local mucosal congestion are most often preceded by slight modifications of the vasculo-connective tissue, sometimes hardly appreciable locally. These slight modifications bring about local and general subjective disorders, such as the sensation of local uneasiness, swelling, pain, general malaise, and in the more marked cases, the appearance of nausea, asthenia, cardiac disturbance, and rise of temperature. Sometimes there is an enormous disproportion between the small doses given and the severity of the effects produced in the local tissues and on the general condition. The general effect of these symptoms necessitates the moderation of treatment, because apparently trifling lesions of the vasculo-connective tissue, and symptoms hardly appreciable during the course of the treatment, are sometimes, after three to four weeks, followed by marked modifications of the normal tissue, which modifications increase considerably after some years.

The changes in the glandular secretions manifest themselves by subjective and objective phenomena. In particular, when the salivary secretion, for example, becomes too abundant, glandular modifications are already appreciable. One must not wait, before reducing the treatment, until the secretions of the glands of the buccal cavity are thick, viscous, and adherent, until the perversion of taste is absolute and until these disturbances hinder the nutrition of the patient.

THE THREE PRINCIPAL TYPES OF EPITHELIAL RADIOREACTION

Since epithelial radioreactions have been our principal guides during X ray therapy of cancer, it is necessary to learn to recognise them. They are easier to observe than the radioreactions of the vasculo-connective tissue.

The first epithelial radioreaction to be recognised was the cutaneous "radio-epidermitis" described by Regaud and Nogier in 1913. In 1922 I described the "radio-epithelitis" of the mucous membranes of the pharynx and buccal cavity. These two radioreactions occur in the covering pavement epithelial cells. There exists a third reaction, the radio-epithelitis of the columnar epithelial cells.

The three epithelial radioreactions consist essentially in the destruction of the epithelial cells covering the site of the irradiated surfaces. On the mucous membranes they manifest themselves by the disappearance of the epithelial layers, the denudation of the chorion which becomes covered by fibrin and false membranes. The false membranes are sometimes blood-stained, thick, or greyish when the treatment has been too intense or when there is superadded infection. The false membranes ought to be thin and clear if the dose has not considerably overstepped the threshold of reaction. In this case the radio-epithelitis is almost painless; it does not become infected and it is rapidly repaired, leaving no trace. Cutaneous radio-epidermitis presents the same characters, loss of epithelial layers and denudation of the dermis. There should be no tendency to hæmorrhage, there is no objection to the production of a slight exudation, and in this case repair will not be delayed.

When daily doses of approximately 350 to 400 r, in two séances, are given to the skin of the cervical region,[1] the three epithelial radioreactions manifest themselves at fixed periods in relation to the commencement of irradiation. They can be particularly well studied in this region where the different types of mucous membrane are very close one to the other.

The aryteno-epiglottic folds constitute a lateral wall separation between the larynx and pharynx. On the est of this wall there exists a mucous membrane covered very fragile stratified epithelium. In this zone, dio-epithelitis of the stratified cells generally appears wards the 13th or 14th day *after the beginning of* adiation; this is the earliest of the epithelial radio-actions of this region. Lower down, in the larynx, the level of the vocal cords, where the stratified ithelium resembles that of the skin, radio-epithelitis pears, towards the 27th or the 28th day, at the same me as the cutaneous radio-epidermitis. At the level the ventricular bands and below the glottis, on the ucosa covering *the tracheal* rings, the epithelium is lindrical or columnar. Radio-epithelitis of the cylindrical-lled mucosa appears third, towards the 39th or 40th day.

If irradiation is more intense, the radioreactions appear lier, respectively on the 10th and the 24th day, for the o first; sometimes the third reaction appears a very r days after the second. It seems that in the course of an ense treatment, the different varieties of cells lose the perty of disintegrating and disappearing at the times, ed, constant and characteristic of each type; they serve the property only when the irradiation has been mal.

f irradiation is less intense, the radioreactions are arded; they appear towards the 18th, 34th, and 48th s respectively. Under a certain threshold, that is, h less than a certain daily dose, they do not appear ll.

IE DURATION OF EPITHELIAL RADIOREACTIONS

ie repair of each of the three epithelial radio-ions ought to be at its maximum in two weeks its onset, the radio-epithelitis of the stratified-l mucosa ought to be repaired by the twenty-sixth at the time of the appearance of the cutaneous epidermitis. The cutaneous radio-epidermitis, ie radio-epithelitis of the stratified-celled mucosa bling the cutaneous type, ought to be repaired thirty-ninth day, at the time of the appearance of the radio-epithelitis of the cylindrical epithelium. Radio-epithelitis of the cylindrical cells ought to be repaired towards the fifty-fifth day. Altogether the three principal epithelial radiolesions are thus spread over six weeks, that is to say, they appear at the beginning of the third and disappear at the beginning of the ninth week. This at least is what happens if the irradiation has been given in the time and under the conditions indicated above, with a maximum field of 50 square cm.

One ought to endeavour to obtain epithelial radioreactions of 10 to 12 days' duration when treating cancers so extensive that fields larger than 50 square cm. are necessary. For a very extensive cancer, necessitating a field in the order of 100 to 125 square cm., the duration of repair of the radioreactions ought not to exceed eight days.

Above 150 square cm. and particularly for the large abdominal fields of 3 to 400 square cm., loss of the entire epithelial layers ought to be avoided on the skin as well as on the mucosa of the vagina, intestines, or bladder, and one ought to provoke neither cystitis, proctitis, nor enteritis. The epithelial desquamation ought to be effected without laying bare the dermis or chorion, that is to say, the superficial layers only ought to disappear. Cutaneous radio-epidermitis of the abdomen ought to be non-exudative.

THE APPEARANCE OF THE EPITHELIAL RADIOREACTIONS

The two examples of radio-epithelitis, illustrated in Figs. VI. to XV., show that repair of the radio-epithelitis is effected either by central islands of epithelial cells, whose number increases rapidly at first, so that the islands enlarge quickly and become confluent; or by semicircular epithelial surfaces arising from the periphery and directed towards the centre; or by these two means in association. These are the normal methods of repair, indicating that the vasculo-connective tissue has been relatively preserved. If there is greater change, repair is no longer effected by the islands of cells; it is done by linear cellular formations, as can be observed in the central portion of the radiolesions we have chosen for an example. In this region the borders of the lesion are rectilinear and are covered slowly and with difficulty with epithelial formation.

The first example of prolonged cutaneous radio-epidermitis is that of a patient suffering from epithelioma of the left lateral pharyngeal wall, with pronounced adenopathy on the left side.

Treatment was completed in 22 days. The dose was 7000 r in 22 hours, on the side of the lesion, with two *fields of* about *80* square cm., one antero-posterior, the other transverse; the two fields overlapped on their borders.

Radio-epidermitis appeared on the 28th day. Repair was very slow, since on the 11th day (Fig. VI.) the radio-lesion was still very extensive; it was repaired chiefly from the periphery where the semicircular cellular surfaces are to be seen; very few central islands of epithelial cells exist. Between the 11th and the 16th day, *that is*, within five days (Fig. VII.), repair was appreciable, but it was only peripheral. After 34 days (Fig. VIII.) a cutaneous linear lesion remained. At this stage epithelial elements are no longer formed; the epithelial cells appear to be incapable of developing in the modified connective tissue.

Complete repair was only effected on the 43rd day (Fig. IX.), with a visible central scar, accompanied by late œdema. In this case the dose has been distributed in too short a time.

The second example of excessive cutaneous radio-epidermitis is that of a patient irradiated from Nov. 3rd to the 28th, 1931, on the sternoclavicular area, through a single field of 190 square cm.

---

[1] man of average musculature it is advisable not to a period of 13 days a dose of 5000 r, of which 4000 r he same side of the neck, with a maximum field of 50 These are [illegible] we are using less and less [illegible] tolerated them and cure of [illegible] 6000 r in 15 to 16 days, umber of patients cannot stand such doses.

6200 r were given in 27 hours, during 26 days, at the rate of two séances a day. Radio-epidermitis appeared late, on Dec. 11th, 1931, that is, on the 39th day (Fig. X.). Three days later, on Dec. 14th (Fig. XI.), repair was already appreciable; it was both peripheral and central. Central islands of epithelial cells were numerous and two days later, on Dec. 16th (Fig. XII.), the radio-epidermitis was reduced by half. From Dec. 16th to 18th the rate of multiplication of the islands was still rapid (Fig. XIII.). From Dec. 14th to 24th (Fig. XIV.), that is to say, in 10 days, the diminution of the surface deprived of epithelium was normal and it seemed clear that final repair would follow. But the lesion then diminished slowly, the radio-epidermitis became linear in the centre, and the connective tissue appeared no longer able to provide for the nutrition of the epithelial cells. Repair was only complete on Jan. 10th, 1932, on the 30th day.

In this case the connective tissue has been too much modified by the rays, as is shown by the appearance of the skin two years later, on Oct. 12th, 1933 (Fig. XV.). Here is shown a permanent alteration in the skin with dyschromia and sclerosis. It would have been better to reduce the dose to 5000 r, considering the large dimensions of the field, or else substantially to prolong the duration of the treatment.

This excessive duration of radio-epidermitis and also of radio-epithelitis is caused by an exaggerated modification of the vasculo-connective tissue. In these conditions the nutrition of the epithelial cells is imperfect; these cells at first multiply rapidly, then more and more slowly because there is more and more difficulty in finding the substances necessary for their metabolism. It becomes an effort to cover over the whole surface of the dermis or the bare chorion. No wound is repaired so slowly as is a radio-epidermitis if the vasculo-connective tissue has been damaged by irradiations; and on the other hand no wound is repaired so quickly if the vasculo-connective tissue has been preserved, while the naked-eye appearance of the two lesions differs very little.

General Biological Principles

THE EFFECT OF VASCULO-CONNECTIVE TISSUE RADIO-REACTIONS ON RADIOSENSITIVITY OF CANCER CELLS

Like the nutrition of the normal epithelial cells in the course of the repair of a radio-epidermitis, the nutrition of the cells of an epithelioma during irradiation is dependent upon the conservation of the medium, in which it lies, that is, of the vasculo-connective tissue.

If the total dose, or the daily dose, or the intensity per minute has been too high, if the field has been too large in relation to the doses, or if the filtration or the tension has been too low, the connective tissue may be modified. The nutrition of the epithelioma cells thus becomes difficult. The cellular radiosensitivity, which seems to be linked up not only with the youthfulness of the cells but above all with the activity of their interchanges with the vasculo-connective tissue, is modified, often diminished, and sometimes suppressed. The cancer cells behave clinically as if they had become insensitive to the irradiations. This is what Regaud described in 1913, under the name of "radiovaccination," after an extremely careful study of a case of spindle-celled sarcoma of the scalp which became radioresistant in the course of intense and repeated treatments.

In the case of a very embryonic tumour, such as lymphosarcoma, or an undifferentiated epidermic epithelioma, the radiomodifications of the vasculo-connective tissue have a very slight effect

upon the radiosensitivity of the cancer cells be
this sensitivity is pronounced. In a highly diffe
ated tumour, either an epidermoid epithelioma
prickle cells predominating, which is infiltratin
muscle, or a tubular adenocarcinoma, the
modifications of the vasculo-connective tissue
the utmost importance because the radiosensi
of these tumours is feeble.

In the first case, the effect of X rays on

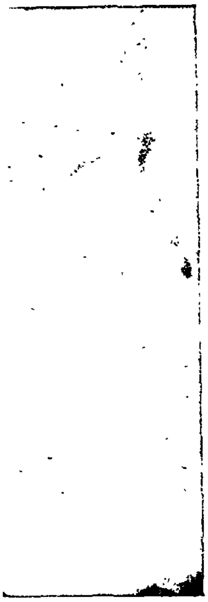
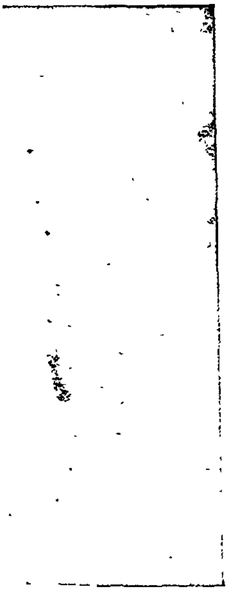
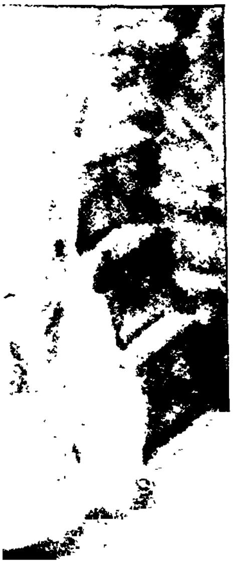
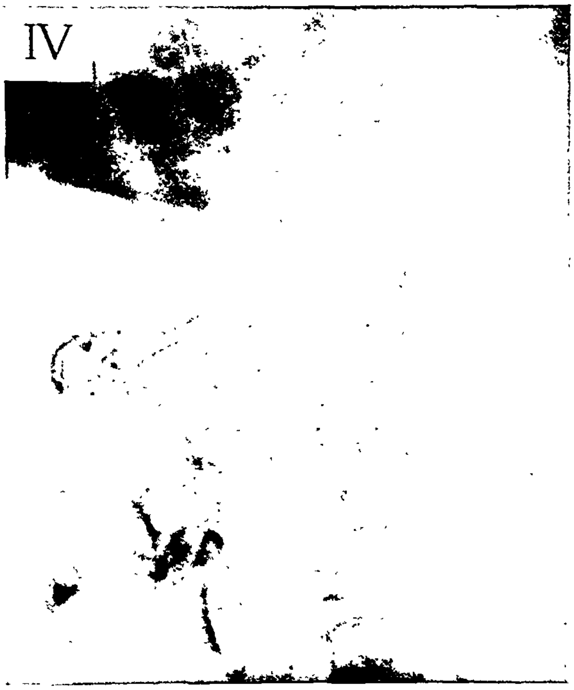
DR. HENRI COUTARD: PRINCIPLES OF X RAY THERAPY OF MALIGNANT DISEASE









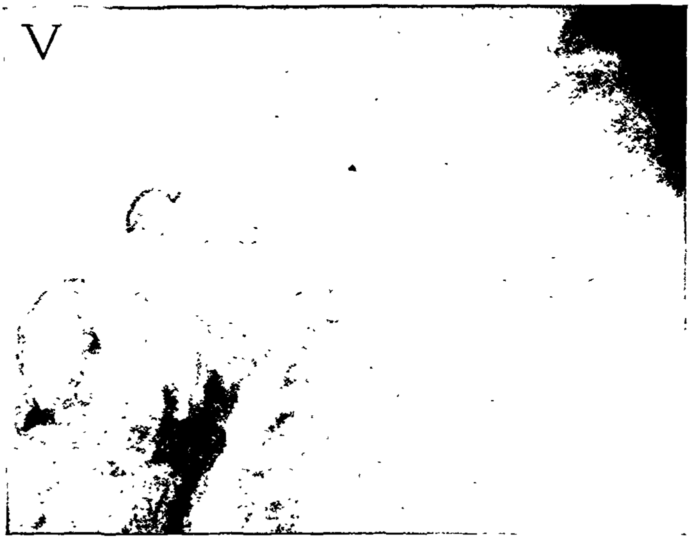


FIG. I

Epithelioma invading the whole larynx, and necessitating tracheotomy. Anteriorly, the pre-epiglottic region is invaded; posteriorly, the neoplasm extends beyond the arytenoid fold and reaches the posterior part of the cricoid.

FIG. II

Regression of the lesion a month after the beginning of X ray therapy. The laryngeal transparent space has reappeared.

FIG. III

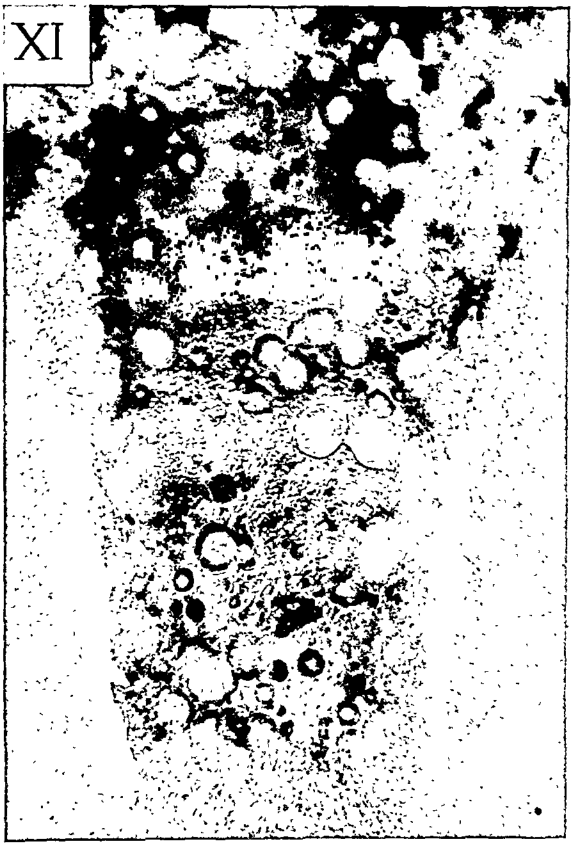
Return to normal, the tracheotomy tube having been removed. A year and a half after treatment the patient is apparently cured locally.

FIG. IV

Epithelioma of the hypopharynx, extending from the mouth of the œsophagus up to 2 cm. above the angle of the mandible. The laryngeal cartilages are pushed forward, away from the vertebral bodies.

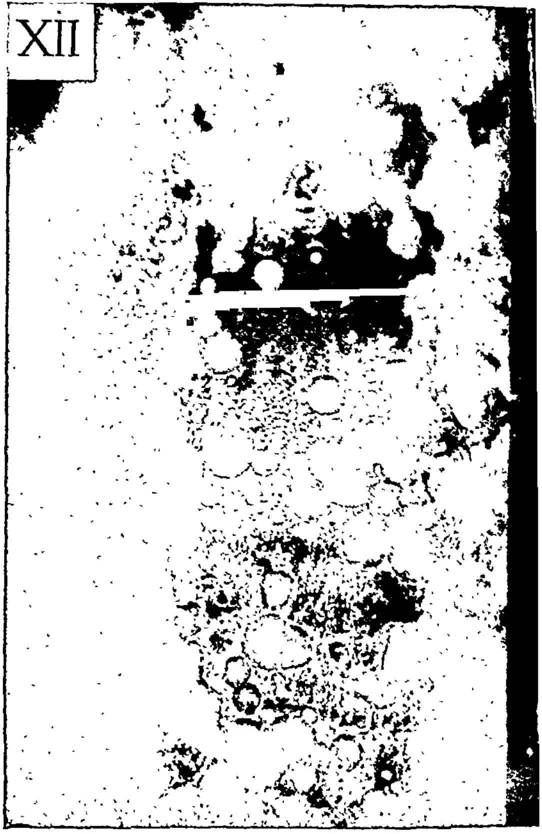
FIG. V

Disappearance of the tumour shown in Fig. IV.: the relation of the larynx to the vertebral bodies is now normal, and the hyoid bone and the thyroid are in contact with the vertebral bodies.



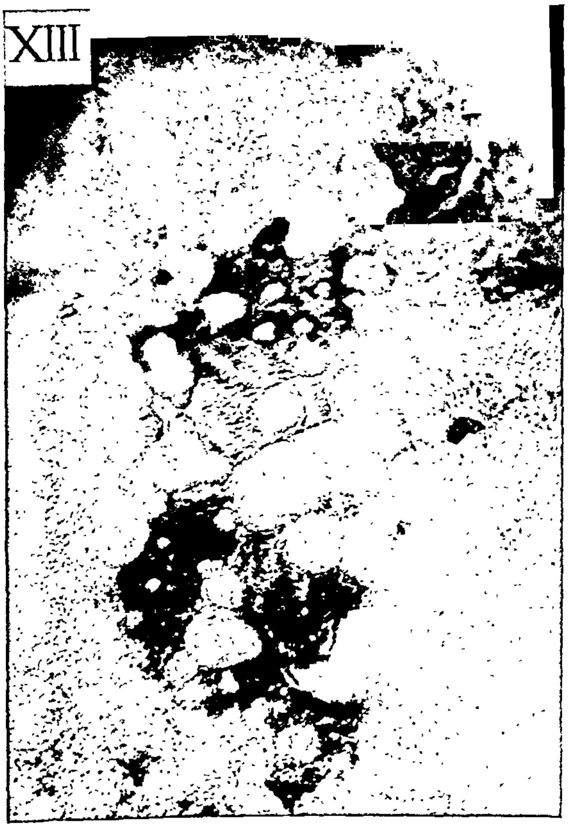
XI

Third day after the onset of radio-epidermitis in case shown in Fig. X. Repair begun by means of peripheral epithelial islands and some central islands.



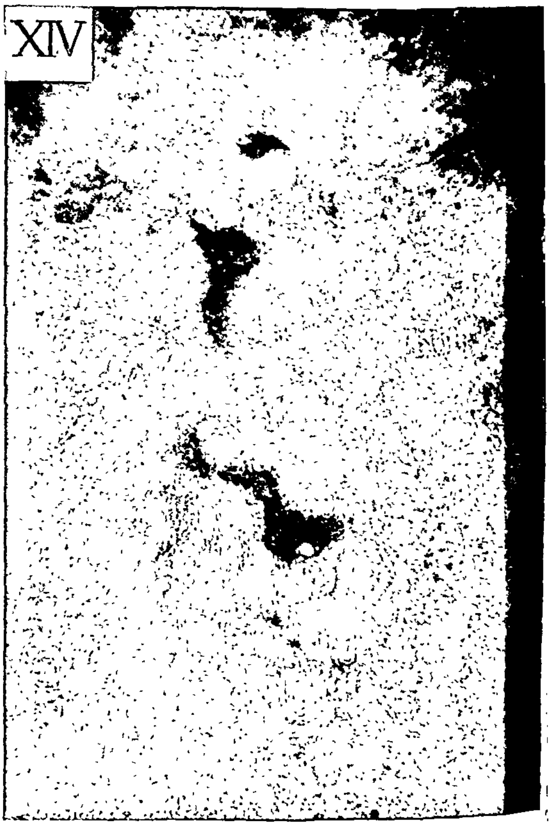
XII

Fifth day. The size of the radio-epidermitis has decrease by half.



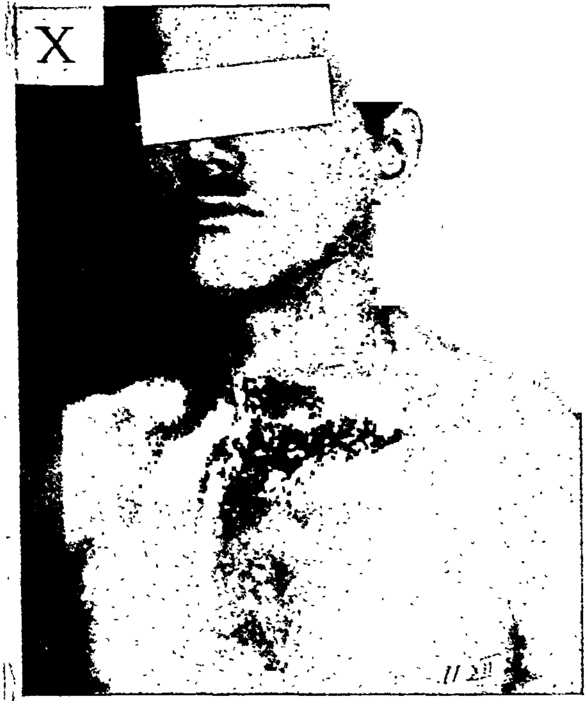
XIII

Seventh day. The radio-epidermitis seems to be diminishing very rapidly.



XIV

Seventeenth day. Repair is still rapid but tends to be no longer effected by epithelial islands but by rectilinear groups of epithelial cells.



Appearance of a radio-epidermitis on the 39th day after the beginning of treatment.

not sufficiently early nor sufficiently great to reduce the radiosensitivity of the embryonic cancer cells in any appreciable manner.

In the second case, the effect of X rays on the differentiated cancer cells is not immediate. It appears slowly, little by little, in the course of a very long time, the exception being for the cells which were in mitosis from the beginning of treatment. If the vasculo-connective tissue remains perfectly normal, the less differentiated cells disappear from the forty-fifth day after the beginning of treatment; the more differentiated towards the ninetieth and sometimes the hundredth day. If the vasculo-connective tissue is modified by the irradiations, experience shows that disappearance of differentiated cells does not occur.

THE DAILY QUANTITIES OF ENERGY AND THE RADIO-RESISTANCE OF THE CANCER CELLS

Up to 1926 we thought that the essential cause of loss of radiosensitivity of the cancer cells, in the course of treatment, was the length of each treatment and we set ourselves to give treatments of short duration.

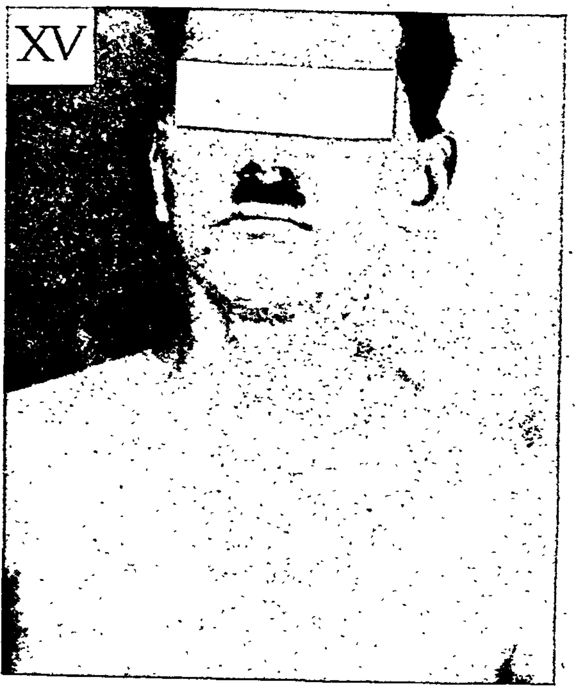
In fact we had observed that cures of certain cancers were obtained only when the duration of treatment had not exceeded 15 to 16 days. After this time the cells seemed to be no longer altered by the irradiations and the general condition of the patient was made worse. In these cases, during the first week of treatment, the skin dose had been very high, 4000 to 4500 r; the remainder, about 2000 r, had been given during the following week, with weaker daily doses. Thus, a dose of 4500 r in six days necessitated giving 750 r per day, that is to say, a considerable daily quantity of energy, with high minute intensity.

Later, we were able to observe that if we gave this same initial dose of 4500 r in 10 to 12 days, instead of six days, it was possible to obtain cure with a longer treatment than in the preceding cases, on condition that the total duration of treatment did not exceed 20 to 21 days. After 20 to 21 days of irradiation the cancer seemed to become insensitive; a treatment of longer duration was generally inefficacious. In these cases the daily dose for the first 10 days was about 450 r. Subsequently, the duration of treatment was progressively increased up to 30 days, then up to 40 days; in this last case, it was possible to obtain cure when the daily dose during the first 10 days did not exceed 300 r. Little by little, also, in the course of years, it became evident that the chronology limit of treatment, beyond which the cancer seemed to become insensitive, was not fixed.

Observation of clinical facts shows us that changes in the vasculo-connective tissue result much more from excessive daily doses and excessive intensity per minute than from the excess of the total dose. Thus, for the same total dose, the daily doses are necessarily increased with diminution of the duration of the treatment. Consequently, the shorter the duration of the treatment and the higher the daily doses, the quicker appear the changes in the supporting tissue, that is, the vasculo-connective tissue, and the quicker is manifested the reduction of radiosensitivity of the cancer. Conversely, radiosensitivity was the longer preserved when the daily doses were weaker, that is to say, when the duration of treatment was longer, always provided that the daily doses were not less than the threshold dose necessary for the disappearance of the neoplastic cells.

THE TOTAL QUANTITY OF ENERGY OR DOSE AND THE CURE OF UNDIFFERENTIATED OR NOT VERY HIGHLY DIFFERENTIATED CANCERS

During the years 1920 to 1926 the duration of treatment for the cured epitheliomas was on an average from 15 to 21 days for the larynx, from 25



Same case as shown in Figs. X. to XIV. two years after beginning of treatment; permanent modification of the skin. Dyschromia and sclerosis. The too intense radio-epidermitis (duration 30 days) has taken too long to be repaired. With a field of this size repair ought to be effected in 8 to 10 days.

to 31 days for the hypopharynx, and from 30 to 40 days for the tonsillar region. For lymphosarcomas it was from 13 to 30 days. The total doses for the cured epitheliomas was from 6000 to 8000 r, measured on the skin; the daily doses during the first week were of 350 r for cancers treated in 25 to 30 days, and from 600 to 700 r for cancers treated in a short time. The intensity per minute varied between 3 r and 5 r.

Under these conditions of treatment we necessarily produced considerable modifications of the vasculo-connective tissue; this is why we were only able to cure those epitheliomas in which the changes in this tissue were of little importance, that is to say, the undifferentiated or slightly differentiated epitheliomas. Cure of differentiated cancers or of cancers infiltrating the muscles was exceptional.

We next thought it possible to obtain cure in differentiated cancers by increasing the dose. These efforts were fruitless. Under the same conditions of treatment, *increasing the dose above 10,000 r up to 12,000 r, and even 15,000 r, never gave us a single case of cure* but always aggravated the general condition of the patient; modifications of the vasculo-connective tissue were more and more marked and demonstrated more and more clearly the loss of sensitivity, besides radio-accidents of all kinds.

THE SYSTEMATIC LENGTHENING OF THE CHRONOLOGY OF TREATMENT AND THE CURE OF DIFFERENTIATED EPITHELIOMAS

Since we became convinced that radioresistance of cancers is the result of excessive daily doses and too high intensity per minute, acting through *modification of the vasculo-connective tissue,* and was not due to treatment having been spread over too long a time as we had formerly believed, we were naturally led to prolong the duration of treatment for cancers which seemed to us to derive benefit from this prolongation.

It was for this reason that from 1927 to 1933 we have, with our collaborator F. Baclesse, extended the duration of treatment for certain cancers, *little by little,* from 30 to 90 days, by means of *weak daily doses* (in the order of 175, 200, 225, or 250 r per day), distributed in two séances, without varying the other factors and particularly the size of the fields. We were able thus to obtain disappearance of cancers which up to then we had considered radioresistant and which we had never cured, such as very differentiated epidermoid epitheliomas, invading the muscles and cartilages, glandular epitheliomas of the breast and of the thyroid body, and special round-celled epitheliomas of the upper part of the ethmoid and adjacent sinuses.

In glandular cancers of the breast we had only, up to then, using heavy doses given in under 30 days, obtained amelioration, exceptionally definite disappearance, or even local disappearance followed by the development of lesions in neighbouring glands or distant metastases. We believe that, for these very differentiated tumours, rapid and intense X ray therapy, given in less than 30 days, is often one of the causes of the development of metastases. On the contrary, the treatment of very differentiated epitheliomas *by small doses,* capable of preserving the vasculo-connective tissue, that is to say, by small daily doses repeated over a period of 45, 50, and even 70 days, seems to us actually more favourable and gives us better results not only locally, but in a slower development of glands, and in a lessened frequency of metastases.

Present Knowledge of X Ray Therapy of Cancer

THE TIME FACTOR

Alongside the energy factor, considered *originally* as the sole factor or at least essential to the X ray therapy of cancer, the daily repetition of irradiation in doses either uniform or unequal and the increase in the number of days of treatment, have provoked a second factor, the time factor. This time factor has long consisted in a chronological distribution of the irradiations so that the general and local accidents *observed previously might* be avoided, thanks to an increase in the difference of sensitivity between the neoplastic tissues and the normal tissues. The chronology was, above all, protective, at least in principle, for actually it did not always succeed in protecting the normal tissues against post-X ray complications. Complications and accidents in X ray therapy of cancer, when the treatment is identical, appear or do not appear according to *variations in individual susceptibility. The vasculo-connective tissues are shown to be very fragile or very resistant in individual patients.*

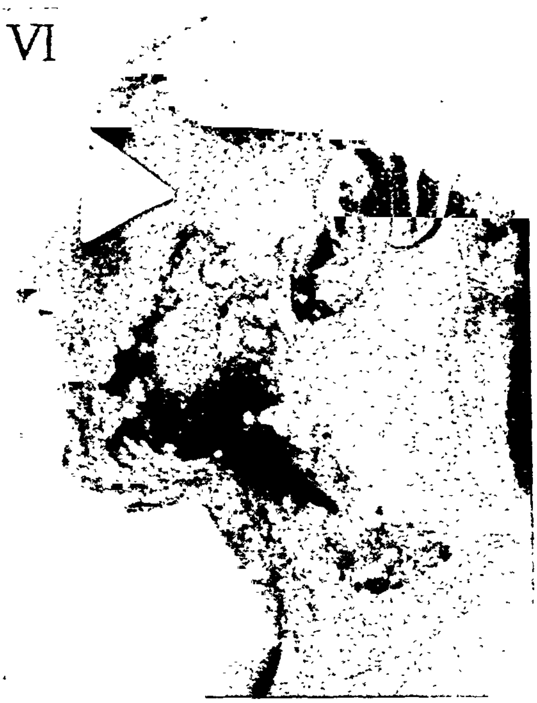
As regards the embryonic cancers, where it is sometimes possible to give treatment in short periods of from 18 to 20 days, a good chronological distribution can ensure protection to the surrounding tissues. As regards the differentiated cancers which we now treat over a long period, notably 45, 50, 60 days or more, the chronology has a different character. On the one hand, accidents to the general tissues are exceptional on account of the long time over which treatment is spread. On the other hand, disappearance of the cancer cells does not happen by cellular destruction between the eighth and twenty-fifth day, as in embryonic cancers, but by a sort of late cellular evolution, similar to the normal evolution. Between the forty-fifth and the ninetieth day we see the neoplastic masses, which have generally diminished in volume during the previous irradiations, increase anew for eight to ten days, giving the impression of a *rapidly growing* recurrence, then cover themselves *with horny formations or glandular secretions* and diminish anew in size and little by little disappear. For this slow evolutionary effect to be produced it seems necessary for the treatment to be carried out over a very long period, by means of very small daily doses. The chronology is no longer protective; it seems to be evolutionary.

CANCERS OF VERY EMBRYONIC TYPE

In the treatment of very embryonic, very radio-sensitive cancers, the energy factor is predominant. The action of X rays seems to be a direct one; it is rapid; the cells die very soon and have generally disappeared towards the twenty-fifth day. The medium, the vasculo-connective tissue, only plays a very small part. Whereas it is sometimes modified by the irradiation, it is more often modified after the destruction of the cancer cells. *It is possible,* moreover, to find no modification whatever of these tissues. Sometimes the covering tissues reveal not a single trace of the irradiations, as if the dose delivered had corresponded exactly to the quantity of energy necessary for the destruction of the cancer cells and as if the energy was entirely utilised by these cells.

The time factor, as I have said above, enables us mainly to achieve the *preservation* of the general tissues and to avoid early or late accidents.

VI

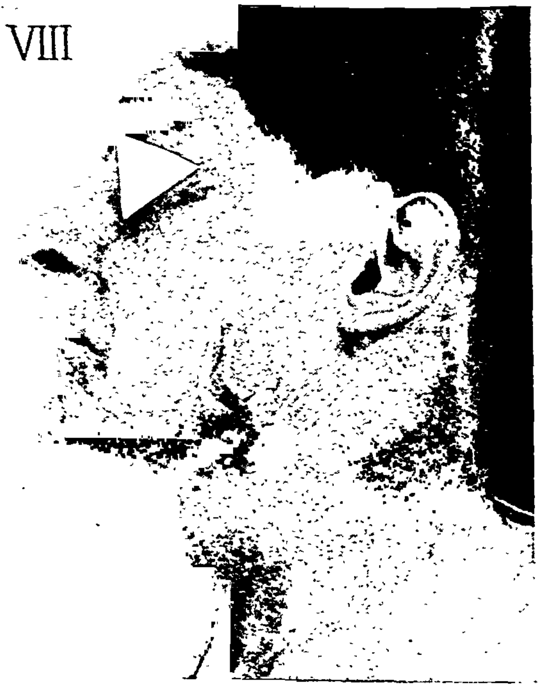


In this case radio-epidermitis appeared on the 28th day after the beginning of treatment. This photograph was taken on the 11th day of the radio-epidermitis, when repair is being accomplished by groups of epithelial cells arranged in a semi-circle at the periphery of the lesion.

HIGHLY DIFFERENTIATED CANCERS

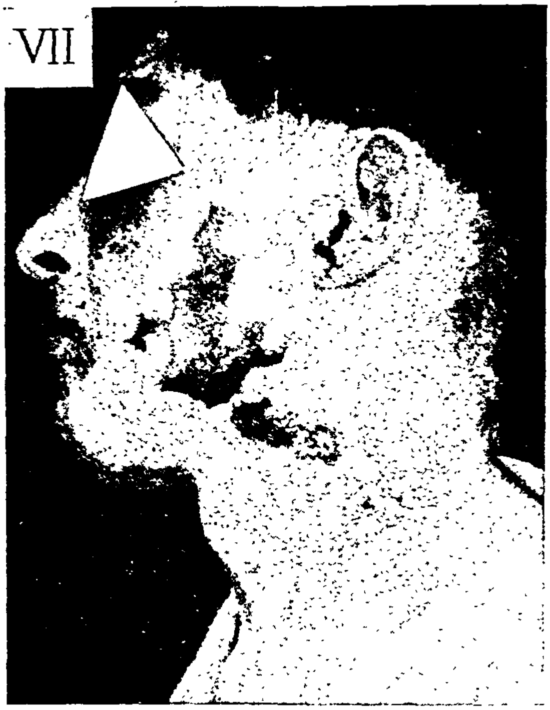
In the treatment of highly differentiated, radio-resistant, extensive, and deeply situated cancers it is quite a different question. The time factor is predominant. The question of energy, dose, and destructive effect gives place to the question of radio-evolution and evolutionary chronology.

VIII



Thirty-fourth day. A linear cutaneous lesion remains. Very slow repair.

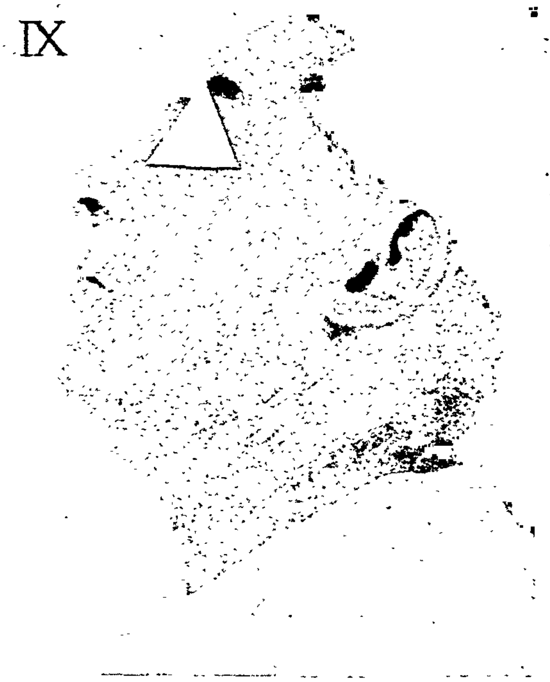
VII



Sixteenth day of radio-epidermitis. Repair goes on only from the periphery. No central islands of epithelium.

The supporting tissues play a predominant rôle. The action of the X rays seems to be indirect, slow, and late. The energy carried each day to the cells ought to be feeble, since it aims at slowly bringing about the evolution effect, that is, the maturation of the cancer cells. It seems only possible to achieve this if the neoplastic cells assimilate little by little,

IX



Forty-third day. Repair with central scar and late œdema. The duration of radio-epidermitis has been much too long.

according to their needs, part or all of the slowly delivered energy. If the energy is delivered too rapidly or in too short a time, if it is *greater than that* which the cells need, the excess of energy seems to be absorbed by the vasculo-connective tissue and by the general tissues. Modifications of the vasculo-connective tissue result from this and appear to reduce or annul the evolutionary process.

RADIO-EPITHELITIS OF CANCER CELLS

Embryonic epitheliomas are sometimes covered with thick false membranes some days after the beginning of irradiation. If the cancer is not infected, one can thus witness the early appearance of radio-epithelitis of cancer cells. The false membranes may be confluent from the sixth or seventh day. They therefore precede by some days the radio-epithelitis of the fourteenth day, that is to say, of the normal epithelial cells which surround the cancer. The *radiosensitivity of the cancer cells* is at this time definitely greater than that of the normal neighbouring mucosa. In these cases cure is usually easily obtained, even after a treatment of short duration. If the cancer cells are covered with false membranes some days after the appearance of the radio-epithelitis of the normal surrounding mucous membrane, it is because their radiosensitivity is less than that of the mucosal cells. Cure is more difficult to attain and necessitates a longer period of treatment.

Among the differentiated cancers only the stratified epidermoid epitheliomas and the cylindrical-celled epitheliomas give rise to radio-epithelitis and in an inconstant manner. When *it appears it is always very* late. It is produced a long time after the radio-epithelitis of the *stratified mucosa* which is spread between the fourteenth and the twenty-eighth day. It sometimes appears towards the thirty-fifth day, at other times towards the forty-second, and at still other times towards the fifty-fifth day, according to the type of epithelioma.

Summary

The two principal factors in X ray therapy are the energy and the time. They must be considered in their relation to the cancer cells on the one hand, and on the other hand to the vasculo-connective tissue and the general tissues of the site from which the cancer is developing.

In the course of treatment the principal guides have been, for us, the *radioreactions of the vasculo-connective tissue*, the radioreactions of the covering epithelium, and the radioreactions of the cancer cells.

When one is irradiating a cancer of very small size and very embryonic in type, the treatment can be completed in a short time, about 20 days; the epithelial radioreactions may be relatively intense, on condition always that their duration never exceeds 15 days.

When one is *irradiating a cancer* less embryonic in type, the treatment ought to be of longer duration, and the epithelial radioreactions ought to be slight.

When it is a question of a very extensive cancer, irradiated through fields of large dimension, as in the case of cancer of the uterus, the treatments ought to be from 40 days as a minimum; the cutaneous radio-epidermitis ought not to be exudative; and the radio-epithelitis of the vaginal, intestinal, or vesical mucosa ought to be very slight. Symptoms, even temporary, of cystitis, proctitis, or enteritis, ought to be avoided.

The question of energy—i.e., of the cancericidal dose—is essential in the treatment of an undifferentiated embryonic, radiosensitive cancer, and it is more important than the question of time. The energy seems to be directly destructive; the chronology is, *above all, protective*, since it allows the preservation of the supporting tissues in order to avoid accidents.

The question of time is more important than the question of energy in the *treatment of a differentiated*, radio-resistant cancer. The energy ought not to provoke a destructive effect. Thanks to a slow chronology and to weak daily doses, the disappearance of the cancer cells seems to follow a cellular evolution resembling the normal evolution. In determining the longer duration of treatment one should aim at the perfect preservation of the supporting tissues so that the evolution effect may become possible.

In conclusion, I would say that it is still absolutely necessary to bear in mind that:

1. The cure of cancer by X rays is still difficult.
2. The cure of cancer by X rays is still dangerous.
3. A very small margin exists sometimes between the dose which will determine a cure and the dose which will provoke an injury.
4. The daily examination of the patients is necessary; modification of the normal tissues and of the general condition by X ray treatment sometimes appears so quickly that it is often necessary to diminish the daily dose or the size of the fields in the course of the treatment.

There exists no fixed method of treatment but a simple clinical treatment for each *individual patient* and for the special type of tumour.

I would like to express my gratitude to the directors of the Marie Curie Hospital for the great honour they have done me in inviting me to speak here on the occasion of the opening of the new X ray department, and to Prof. Regaud, chief of the Institute of Radium of the University of Paris, who, for 15 years, has helped me with valuable advice. I have also to thank Dr. Jean Riach for translating this lecture.

THE DANGEROUS MULTIPARA *

BY BETHEL SOLOMONS, M.D. Dub., F.R.C.P. Irel., F.C.O.G.

LATE MASTER OF ROTUNDA HOSPITAL, DUBLIN; GYNÆCOLOGIST TO DR. STEEVENS' HOSPITAL, DUBLIN

MY object in writing this paper and giving it a sensational title is to remove if possible, once and for all, from the mind of the reader the idea that a primigravida means a difficult labour but a multipara an easy one. The primigravida gives the impression of difficulty just because she is an unknown entity, and more attention is focused on her both in pregnancy and labour than on the woman who has "done it before." But it is altogether a mistake to suppose that in childbearing practice makes perfect. Furthermore, the multipara is probably more important to the State than the primigravida, and demands equal care. She is the more skilled housekeeper and she knows the weaknesses of her husband; she is the mother of one or more *children, and it may* be taken as an axiom that mothers cannot be replaced.

During the first four years of my Mastership, in 8333 births in the intern department of the Rotunda there were 4975 multiparæ, a percentage rate of over 59. Among them there were 34 deaths, or 0·7 per cent., and this mortality was slightly higher than that of primigravidæ (0·67). An interesting study from the Department of *Health for Scotland* shows that while primiparæ have a mortality 7 per cent. under the average and 2-paræ nearly 40 per cent. under, from the fifth pregnancy the rate of mortality is over average by an amount which increases steadily and speedily until in women bearing their tenth child or more the mortality is five times as high as for all women bearing children.

* Portion of a paper read at the fourth annual meeting of the Central Association of Obstetricians and Gynæcologists, Memphis, Tennessee, U.S.A.

THE WOMAN WITH THE PENDULOUS ABDOMEN

There is no more difficult proposition in midwifery than the woman with the pendulous abdomen. First, the abnormality may be missed until it is too late to act, and secondly, the presentation may become abnormal after the time when it is possible to correct it with safety for mother and child. The possible outcomes are: (1) occipito-posterior and brow presentations due to the fœtus lying in an incorrect axis; and (2) rupture of the uterus from attrition or actually from thinning of the lower segment due to disproportion.

Contraction ring dystocia due to disharmony of the uterine muscle may be present, and may be due to what might be called natural causes, or to the administration of such drugs as pituitary extract. A strong and loud enough warning cannot be uttered against the use of this type of drug. Rupture of the uterus is common when pituitary extract is administered at the wrong time, and contraction ring may occur. Irregular contraction, with some separation of the placenta, may cause and has caused death of the fœtus.

What can we do to prevent these abnormalities when a pendulous abdomen is discovered or when the patient is seen either in threatened rupture or just leading up to it? This at first seems simple, for a tight binder should work the miracle: alas, this is not so, and danger may speedily become obvious if something is not done. In the early stages, when it is seen that the binder is not doing its job, version must be considered; in later labour version is definitely indicated and the difficulty is to decide on the best time for doing it.

If the patient is seen early, a binder is applied: the attendant should see if the presenting part is being kept in the axis of the inlet. After she has had some labour version must be done if the head is not inclined to fix: if, on the contrary, the head is fixing all will be well and vaginal delivery will be easy. It is very simple to say "perform a version," but if possible this should be left until the time when delivery can be terminated—that is, when the cervix is fully dilated. Sometimes version cannot be postponed so long and it may be necessary to perform it when the cervix is half dilated. On no account must the delivery be completed then. It may be asked if there is risk in this manipulation, and the answer is emphatically in the affirmative: there is risk to the mother if the case is left too long—that is until symptoms and signs of threatening rupture are imminent—and there is risk to the child of prolapse of the cord either during the version or afterwards. Generally speaking, however, prolapse does not occur.

To repeat, if a pendulous abdomen is discovered it must be corrected before danger sets in. This pendulosity may or may not be accompanied by such abnormal presentations as brow, persistent occipito-posterior, and face. Whether these are present or not, version is the proper treatment when the head is not engaging after some labour. I have seen contraction ring dystocia in 10- and 12-paræ, some complicated by marked asynclitism, treated successfully by version. But, on the other hand, a neglected case of this kind will often end in perforation.

A disastrous case of a 3-para illustrates so many conditions that it is mentioned here. There was warning of her trouble, for there had been a transverse presentation with neglected shoulder at the second labour. The pelvis was normal. She was seen antenatally, but it was impossible to get a polar presentation. (This was a case where prenatal care was of no avail.) Even in labour it was difficult to keep a pole down and difficult to turn. Lower-segment section was decided on, but it was found the baby was dead, so she was put back. A contraction ring occurred. It was impossible to reach the neck. The arm was amputated and threatened rupture was present. The thorax was emptied, but the version was so difficult that it took three-quarters of an hour to reach the leg. It was impossible to deliver the head without perforation, so it was delivered by means of two Schultz forceps after decapitation. This patient developed severe sepsis, which was treated by hysterectomy. A large necrotic fibroid with an abscess in the right parametrium was discovered. She recovered. Probably the fibroid was the main cause of all the trouble. Although fibroids are not very common in the very multiparous woman, they must be remembered as a possible cause of dystocia.

Such examples as a 17-para whose labours were normal until the 15th, when operative measures were necessary, and a 20-para who went into threatened rupture after 19 previous normal labours could be multiplied scores of times.

ECLAMPSIA

Some years ago it was thought that eclampsia was essentially a disease of the primigravida. We now know that the multipara is just as liable to it, and when eclampsia develops with her it is probably more dangerous than for the primigravida. It is difficult to tell the reason for this. Probably her kidneys are in a less satisfactory condition than those of her younger sister. She is nearly always comatose; often her blood pressure is quite low, and she secretes but little urine. In the last investigation made the mortality for eclampsia was 1·4 higher in the multipara than in the primigravida. Another point about the multiparous eclamptic is the atypical picture, so difficult that it is well-nigh impossible to know if the case be one of eclampsia or of something else. With the primigravida, once she is over her actual eclampsia the danger is fairly well finished. With the multipara, we often do not know where we are. The following is an unusual case, but exemplifies these remarks:—

A 3-para did not attend the prenatal department. She was admitted with a history of having had two fits. She was very restless. Blood pressure 122/70; semi-conscious. Baby stillborn. She improved after the birth but was restless and difficult to manage; 32 hours after the birth fits began again and continued despite all treatment until she had had 29 fits, when she died. The post-mortem report was atypical for eclampsia and exemplifies not only the danger of eclampsia in the multipara, but also the difficulty of determining whether a patient has eclampsia or not.

Besides eclampsia, all other varieties of toxæmia may be encountered. Toxæmic hyperemesis is a dangerous and often fatal complication for the multipara.

ACCIDENTAL HÆMORRHAGE

This is essentially a disease of the multipara; in fact, so seldom is it seen in the primigravida that when it does occur one is inclined to question the diagnosis, which is more likely to be a very heavy "show," marking the onset of labour, or a missed placenta prævia. During four years there were 148 cases of accidental hæmorrhage at the Rotunda Hospital. Of these 130 were in multiparæ. It should be possible to prevent this disease to a large extent. By getting women to attend the prenatal department regularly, the onset of the kidney condition should be diagnosed and trouble stopped. Too often, however, the patient appears absolutely moribund, with kidneys so damaged that further metabolism is impossible. I do not intend to say anything about treatment except that sub-mammary injection of saline will often save the patient, who will die if local treatment is resorted to too soon.

CONTRACTED PELVIS, DISPROPORTION, MALPRESENTATIONS

It may seem strange that these three are considered together, but they may all occur in the labour of a multipara who has had absolutely normal births on previous occasions. On this account, therefore, she is a very dangerous multipara when any of these abnormalities happen. When disproportion occurs in the multipara the cause must be found; besides pendulosity the principal causes are contracted pelvis, large babies, and malpresentations.

There is no doubt whatever that some women grow contracted pelves or large babies as they become more multiparous. The mystery of the acquired contraction is difficult to elucidate, but it is not uncommon for a woman who has had perfectly normal confinements on all previous occasions to exhibit signs of dystocia perhaps on her eighth effort, and in Ireland "eight" is a common number, while I have seen even the 25-para on not rare occasions. At this eighth effort she shows all signs of delayed labour, and when an investigation is made it is found there is nothing wrong but a marked promontory. Whether this is due to injury of the joint from previous labours or a definite rheumatic affection is a problem; suffice it to say that these cases must be dealt with on the same lines as contracted pelvis in the primigravida.

Increasing size of the baby without change of husband is usual—a fact which was borne out by the investigation of 100 consecutive cases of primigravidæ and multiparæ taken at random. It was found that the average weight in the former was 7 lb. 6 oz. and in the latter 7 lb. 9 oz. The excessive size may not necessitate active treatment, but it may cause trouble, and it is one of the reasons for which the unwary practitioner may find himself in difficulties. This is the type of case where failed forceps and ruptured uterus may be found—the case which requires extreme patience before efforts are made to deliver; in fact, such efforts should not be made until all conditions are fulfilled whereby delivery can be performed without danger.

This is the case, too, where pituitary extract and kindred substances are dangerous, and ruptured uterus may occur when these drugs have been administered at the wrong time. A breech, either arrested at the brim or impacted in the cavity, is probably the most common malpresentation. Many times I have been called to see a very multiparous patient who has failed to deliver herself of a breech—the practitioner having tried every means he knows to help her but without success. There is no contraction ring unless he has been very vigorous in his methods; the baby is still alive. The best method of treatment is to hook the finger into the anterior groin, if necessary pulling with the other hand on the wrist. The method by which the breech is pushed up and the leg brought down has the danger that if movements of the operator are violent, harm to the extent of rupture may result. A very good plan is to put the forceps gently on the breech: traction will then bring the baby low enough to allow finger traction on the groin. If vaginal methods fail, the lower-segment section should be chosen.

Brow presentation must be sought for and treated, while face and occipito-posterior presentation may also be present.

PLACENTA PRÆVIA

Placenta prævia is not a dangerous condition and the mortality should be approximately nil. In 78 cases at the Rotunda in four years there was no death. Of these 70 were multiparæ; this is natural, for the theories of this disease all point to the multipara. In a paper read before the British Medical Association at Manchester, I suggested that the fault lay in the endometrium; that there had never been a repeat case in my practice; and that a prophylactic curettage two months post partum would prevent further placenta prævia. Since that, in collaboration with one of my post-graduate students, Dr. H. E. Canter, I have given further evidence [1] that placenta prævia can be avoided in the multipara. While in no way advocating curettage as a routine for all women with heavy menstruation, there is much to be said for it where a woman has had one or two miscarriages, followed by heavy menstruation; for this is the type of woman who subsequently has a low implantation.

The diagnosis of placenta prævia should be nearly certain without vaginal examination, and this examination should not be made until the operator is ready to perform version, if that is the favoured treatment. Under no circumstances after version should delivery be hastened in any way whatever.

ADHERENT PLACENTA

I have never seen a true case of a morbidly adherent placenta in the primigravida. Retained placenta occasionally requires manual removal because of post-partum hæmorrhage, but very seldom. In the multipara, however, adherent placenta may occur, and as this is one of the most dangerous complications of obstetrics its importance must be stressed. The danger of inserting the hand in the uterus must be especially emphasised, for infection and death are likely to follow. The morbidly adherent placenta is often accompanied by chronic renal disease, so the patient is a bad subject but, even in the absence of this, danger is ever present. May I offer a suggestion in this connexion? When the hand which has been placed in the uterus is removed, it should be reinserted to make sure the uterus is clear. This may have to be done two or three times before one is satisfied. After its withdrawal from the uterus, therefore, this hand must not be removed from the vagina until the operation is complete: in other words, the hand is inserted in the uterus, the placenta is removed, but the hand remains in the vagina.

RUPTURED UTERUS

In four years at the Rotunda there were 10 cases of ruptured uterus, nine in multiparæ; the one primigravida was a case of neglected face presentation after the use of oxytocic drugs. All could probably have been avoided either by careful prenatal care, or by carefully watching the patient in labour, or both. The reasons for rupture were as follow:—

1. The injection of 10 international units of pituitary extract for second-stage delay; this woman was a 3-para who had had two normal confinements. This illustrates the danger of pituitary extract. Even small doses in the early stages of labour predispose to contraction ring dystocia, retained membranes, and post-partum hæmorrhage. The only really safe time is after the third stage is completed.
2. A "quiet" rupture which probably followed an incomplete rupture in a previous labour.
3. Face presentation and contraction ring in a 6-para.

4 and 5. Neglected shoulder.

---

[1] Surg., Gyn., and Obst., 1932, liv., 790.

6. Pendulous belly. Rupture followed neglect to perform a timely version.
7. Partial rupture after a previous lower-segment section. Mother and child were saved.
8. Ruptured uterus after efforts to overcome contraction ring.
9. The uterus was ruptured at 18 weeks through faulty insertion of sea-tangle tents.
10. Pendulous abdomen in a 14-para.

FAILED FORCEPS

The practitioner who knows he should not apply the forceps before the cervix is fully dilated in the primigravida may let his conscience slide for the multipara. But let him beware: an undilated cervix, a head in the upper strait, will spell danger if the forceps are applied. The practitioner may be lucky with a few cases where he has applied the forceps too soon, but the day will come when a dead or mutilated mother and a dead or injured child will bear witness to his ignorance of the first principles of midwifery. The importunities of relations or friends constitute no excuse for the failed forceps. High forceps are always dangerous for mother and child; they should never be applied. Mid-forceps spell danger; they may occasionally be necessary. Low forceps is a safe operation.

Among the few examples of failed forceps encountered in the Rotunda, we have found that spontaneous delivery or an easy forceps delivery occurs any time from 6 to 24 hours after admission. Occasionally a lower-segment section has been necessary, and the fact must be stressed that this operation can be done after failed forceps. It is never necessary to destroy a live child.

Vaginal delivery after section is quite justifiable at the present day, but the patient who has had a section *must* be confined in a hospital with proper equipment; signs of threatened rupture in this class of case must be known; these are a red vaginal discharge accompanied by tumultuous movements on the part of the fœtus, with distress demonstrated by rapidity in the fœtal heart rate.

DRUGS

The multipara with the flabby uterus must not be given any oxytocic drug. She may develop contraction ring dystocia even after only grs. 10 of quinine. Pituitary extract and thymophysin may produce the same effect. Several cases of this kind have been admitted to the Rotunda, and A. Probstner[2] has reported five similar cases of which only one survived. It is safer for the general practitioner to reserve pituitary extract for the termination of the third stage.

CONCLUSIONS AND SUMMARY

(1) At the Rotunda Hospital the percentage mortality-rate of primigravidæ and multiparæ is about the same. As the ratio of multiparæ to primigravidæ is about 59 to 41, more multiparæ die than primigravidæ. (2) This danger to the multipara is amply confirmed by a statistical inquiry from the Department of Health for Scotland. (3) The multipara with pendulous abdomen is a grave obstetrical problem. If treatment is not carried out at the correct time dangerous symptoms may arise. (4) The death-rate for multiparous eclamptics is slightly higher than for the primiparæ. (5) Of 148 cases of accidental hæmorrhage 130 were in multiparæ. (6) A multipara with no history of previous disproportion may develop symptoms, either because of the increased size of the baby or some acquired abnormality of the pelvis in a subsequent labour. (7) Of 78 cases of placenta prævia 70 were in multiparæ. (8) Morbidly adherent placenta and ruptured uterus are conditions of the multipara. The danger of pituitary extract before the third stage has ended is great. (9) "Failed forceps" is just as likely in the multipara as in the primigravida.

OBSERVATIONS ON ROSACEA

By S. Shone, M.D., M.R.C.P. Lond.
DERMATOLOGICAL REGISTRAR, GUY'S HOSPITAL; AND

G. P. B. Whitwell, M.D. Lond.
MEDICAL OFFICER, DERMATOLOGICAL AND VENEREAL DISEASES DEPARTMENTS OF THE HOSPITAL

In spite of a number of important investigations on the pathogenesis of rosacea, its ætiology remains obscure. During the past decade or so the most noteworthy additions to our knowledge of the malady have been from Barber and Ryle,[1] Brown,[2] Eastwood,[3] and Stokes and Beerman.[4] The work of these observers seems to point to some gastric fault in rosacea—most probably a low gastric acidity—but all appear to agree that this factor alone is insufficient to account for the complexities of the disease.

Numerous morbid conditions have been considered important predisposing factors in rosacea—e.g., focal sepsis, constipation, intestinal putrefaction, intestinal worms, acute infections of the respiratory tract, chronic worry, the menopause, and certain gynæcological disorders. But amidst all this confusion, the gastric factor seems to stand out as of major importance, and this is confirmed both by the history of the average rosaceous patient and by results of treatment.

The typical patient with rosacea is a middle-aged woman who has had chronic "indigestion" for many years. (The term "indigestion" may be taken to cover a whole gamut of symptoms referable to the stomach.) During this period there has been an insidious onset of the features of the disease. A flush, at first restricted to the post-prandial period, later becomes permanent and may be accompanied by pustulation. The indigestion usually antedates the rosacea and, when the gastric symptoms are prominent, this is aggravated. Conversely, if the indigestion is cured, the face tends to get well, although there may remain a permanent capillary dilatation.

Barber and Ryle[1] in 1920 investigated the gastric function of some cases of rosacea by means of the fractional test-meal. Comparing their results with the normal controls of Ryle and Bennett,[5] they came to the conclusion that low gastric acidity was common in these patients. Eastwood[3] and Brown[2] independently confirmed these results, although their findings were not so impressive as those of the original observers. This low gastric acidity was apparently confirmed by the dramatic results often obtained by the exhibition of dilute hydrochloric acid by mouth, the flushing and indigestion both tending to disappear rapidly. Eastwood pointed out, however, that the results of giving acid could not always be correlated with the test-meal findings and that some cases with normal test-meals responded well to acid by mouth. We, too, have noted the dramatic improvement with acid in three cases of rosacea in which the test-meals showed hyperchlorhydria in two instances and *normal acidity* in the other. It therefore becomes obvious that the response to acid cannot always be explained by the existence of low stomach acidity.

With these views in mind we have studied 40 cases of rosacea during the past year, taking careful histories in each. On the assumption that the gastric fault is the prime factor, we investigated these patients not only by means of fractional test-meals but also by a small series of histamine test-meals, correlating our results with the results of treatment and with the findings on physical examination. Of our 40 cases, 33 were women. The ages of onset ranged from 18 to 68, but the majority of the ages of onset lay around 35 years. Most of the women were married and had had children; many of them had those two curious and well-known findings in rosacea—low blood pressure and cold extremities.

CIRCULATORY DISORDERS

Rosaceous patients tend to have cold hands and feet, often accompanied, in the female sufferers, by "dead" or "white" fingers. The latter is a phenomenon related to Raynaud's disease. Exposure to cold induces whiteness or numbness; as the circulation recovers the fingers become blue or cyanotic before resuming their normal colour. The phenomenon may last a few minutes. "Bad peripheral circulation" has been noted by MacLeod[6] in these patients but, although it is common in rosacea, it is not invariable. "White fingers" occur frequently in non-rosaceous women and in some non-rosaceous asthenic men. A poor peripheral circulation may be found in rosaceous subjects with normal systolic blood pressures or with low pressures. It may also exist in those with hyperchlorhydria and those with hypochlorhydria. As far as we observed, the white fingers and cold extremities go on even when the rosacea and the indigestion are materially improved.

We examined the nail fold of a few of these patients under the capillary microscope. There appears often to be a marked dilatation and even tortuosity of the venous side of the capillary loops. Often, too, there was a terminal "knob" or aneurysm on the convexity of the loop. These changes seem to occur in the winter and to disappear in the summer, but we have made too few observations to do anything more than mention these results. During the winter there is a small exudation of serum from the skin capillaries of the hands of these patients, and this gives the skin of the hands a slight thickening, especially over the knuckle folds of the proximal interphalangeal joints. On the whole, the bad peripheral circulation seems more a background to the disease than the disease itself, but it is undoubtedly of some importance in the ætiology, for it is observed more often in rosacea than in most skin diseases.

As is well known, about a quarter of the cases of rosacea have a low systolic blood pressure for their ages. The lowest systolic blood pressure in our series was 100 mm. Hg. Low blood pressure is, however, not an essential feature of rosacea; indeed, we have notes of one case with a systolic pressure of 180 and of another with one of 200. The blood pressure bore no relation to the gastric acidity or to the severity of the rosacea in our series; neither did the presence or degree of the coldness of the extremities bear any relation to the severity of the rosacea, the gastric acidity, or the blood pressure.

SEXUAL AND ENDOCRINE FACTORS

Dysmenorrhœa was conspicuous by its absence in our series. One patient did complain of a "terrible" pain at the periods, but her neurotic nature made us suspect her statement. The following menstrual irregularities were noted: oligomenorrhœa, 2 cases; irregular periods, 1 case; imperforate hymen, 1 case.

The premenstrual exacerbation of rosacea is an interesting subject for speculation. One observant mother told us that her daughter's rosacea began to get worse 14 days before the monthly period, and was at its worst a day or two before the period began; there was amelioration during the actual period. Now, those cases of rosacea which get well with treatment—say with hydrochloric acid—no longer experience any exacerbation during the premenstruum. It is reasonable to assume, therefore, that the action of the premenstruum is to aggravate the gastric fault in most cases and that the premenstruum is without influence when the gastric fault is removed or corrected. If this were not so, and were the action of the premenstruum independent of the gastric factor, one would expect its action to persist after the gastric fault had been corrected.

In some of the irregular bleedings that occur round about the menopause the face is worse with the uterine loss. Why this is so is obscure. Some of the irregular and excessive bleedings of the menopause are associated with cystic follicular ovaries with an excessive formation of œstrin. It is possible that the connexion may be in this factor.

We treated three patients (one a young girl) with injections of ovarian follicular hormone. We used both Theelin (P. D. & Co.) and Oestroform (B.D.H.). The former we administered in bi-weekly doses of 50 rat units and the latter in bi-weekly doses of 1000 and 2000 B.D.H. units. The treatment, in two cases, was supplemented by oral administration of Oestroform tablets and was continued for three weeks. Although we provoked menstrual bleeding in one case previously amenorrhœic, we noted no improvement in the rosacea on this treatment; indeed, after the cessation of treatment, two of the cases seemed to settle down to a natural recovery.

In very many cases of "menopausal rosacea" there has been indigestion for a great many years before the menopause, and the latter seems to act more in the nature of "the last straw" than as a direct cause of the rosacea. It is probable that the menopause merely aggravates the gastric fault and is therefore quite a secondary matter. In three cases we noted that, although indigestion had been present for ten and even twenty years, it was the advent of the climacteric which precipitated the rosacea. In this type of case the rosacea usually begins before the periods have ceased.

EYE DISEASES AND OTHER CONDITIONS ASSOCIATED WITH ROSACEA

The usual ocular lesions are: (1) dilatation of the conjunctival vessels—i.e., rosacea of the conjunctiva; (2) rosaceous phlyctenular conjunctivitis, usually seen on the margin of the limbus and resulting in a leash of conjunctival vessels leading to the phlyctenules; (3) corneal ulceration resulting from the breaking down of the phlyctenules; (4) meibomian cysts; and (5) keratitis. In our series 6 cases had eye lesions, which were as follows: "eyes have been inflamed"—meibomian cyst (1 case); rosaceous phlyctenular conjunctivitis (1 case); corneal ulcer (3 cases); corneal ulcer and phlyctenular conjunctivitis (1 case).

If the face and indigestion respond to treatment the eyes will usually follow suit, but where there is long-standing corneal ulceration the issue is not so simple. One patient had a deep and active corneal ulcer on the right eye, while on the left eye there was simple dilatation of the ocular and palpebral conjunctival vessels. This dilatation was made much worse with acid (as were the dyspepsia and the rosacea) but had practically gone after four days on a bismuth and soda mixture alone, which suited his indigestion and rosacea equally well. Of the six rosaceous patients with ocular lesions, five were women and one was a man.

The eye lesions are possibly of the same nature as those on the face; it is unlikely that they are embolic in origin, as in tuberculous phlyctenular conjunctivitis. The rosaceous phlyctenules, on section, are said to be a collection of round cells. The most probable explanation is that the process is a low-grade pyogenic infection. Apparently the meibomian cyst is not a true cyst but more in the nature of a low-grade chronic inflammatory reaction. The eye lesions usually occur after the rosacea develops, but in two of our series the eyes were affected first. The associated diseases which came to light in the course of the case-histories while we were searching for any possible common factor in our series were very various.

1. Acne vulgaris (3); a history of acne was obtained in one case. Acne scars are rare in these rosaceous patients; in most cases the complexion has been good until the advent of the rosacea.
2. ? Subacute appendicitis (1); recent operation for acute appendicitis (1).
3. Migraine (2).
4. Recent pleurisy with effusion (1); tuberculous peritonitis in childhood (1).
5. Rodent ulcer (nose) (1).
6. Psoriasis (1).
7. Diabetes (1).
8. Hypothyroidism (1).
9. Alopecia areata (1).
10. Cystic cavity in scaphoid (1).
11. Rheumatism and vague history of chorea (1).
12. Vague fibrositis (2).
13. Osteo-arthritis (5), most of them being of the climacteric type.
14. "Rheumatism in fingers and ankles" (1).
15. Hypertrichosis (2).

TEST-MEALS

Fractional test-meals were done in 14 cases and the results were as follows:—

	Cases.
1. Practically complete achlorhydria	1
2. Hypochlorhydria	2
3. Low normal acid	2
4. Normal acid	4
5. Hyperchlorhydria	4
6. Climbing HCl	1

Two cases of hyperchlorhydria, one case of climbing acid, one normal acid curve, and one low acid curve had delay in emptying. Excessive mucus was present in only one case—that which was almost achlorhydric. In no case amongst those with low acidity was the latter explicable by early duodenal regurgitation, as judged by the presence of bile.

Eleven histamine test-meals were given, including three cases which had previously had the ordinary fractional meal. These three cases, as judged by the ordinary meal, had hyperchlorhydria, normal acidity, and low normal acidity respectively. It was thought that the administration of the histamine for the purpose of extending our knowledge of the gastric fault in rosacea would also allow us to study the effect of the drug on the flushing of these patients. Ergamine acid phosphate, 1 mg., was injected under the skin of the forearm. The flush developed in four minutes in the rosaceous areas and then spread all over the face and neck, being accompanied by a throbbing headache. In women, a blotchy redness developed over the neck and upper part of the chest more or less concurrently with the rosaceous flush, until finally the whole exposed part of the head and neck was involved, down to the V-shaped "blouse area." The flush persisted from one-quarter to three-quarters of an hour, and always lingered in the atonic dilated capillaries of the rosaceous area, although it had faded elsewhere. Only one patient, who had hyperchlorhydria by fractional test-meal, did not flush at all with histamine.

The test-meal findings, both histamine and fractional, were, as far as they went, such as would be found in an unselected group of normal individuals of the same age-period. There is therefore very little evidence of any fault in gastric secretion in most cases.

It will be seen that our fractional test-meals (14 cases) gave only one case of achlorhydria—i.e., 7 per cent. Brown[2] found 14 per cent. and Eastwood 8 per cent. achlorhydria in their series of rosaceous patients. Dahl-Iverson, quoted by Connor,[7] gave the following figures for test-meals in normal subjects:—

Age.	Subjects.	Achlorhydria %.
20–30	16	—
30–40	46	9·0
40–50	29	3·5
50–60	26	19·0
60–70	11	37·0

In a review of 3381 fractional test-meals on patients with normal gastro-intestinal tracts, Vanzant, Alvarez, Easterman, Dunn, and Berkson[8] found that achlorhydria increased with age, rising from 4 per cent. at the age of 20 to 26 per cent. at 60, the average incidence being 12·1 per cent. It was further observed that females were more liable to achlorhydria than males. Apperley and Semmens[9] found achlorhydria in 30 per cent. of healthy female students.

The above figures show that in rosacea there is no appreciable departure from the normal in the incidence of achlorhydria, and the latter can be taken as a much better guide to gastric secretory dysfunction than mere subacidity, which is, according to some observers, a common finding in any group of women.

We conclude, therefore, that there is no real evidence of any constant abnormality in the gastric secretion of rosaceous patients. That there is not an active gastritis is suggested by the symptoms, for rarely is there pain or irritation from eating meat, fruit, pips, rough vegetables, or any other foods which would irritate an inflamed surface. Further, the indigestion can continue for as long as ten years without alteration in the test-meal.

GASTRIC TONE

The two things that rosaceous patients cannot tolerate are white bread and very heavy meals. Although white bread is badly tolerated, toasted brown bread is usually well borne. In this connexion the observations of Lehman and Gibson[10] are interesting. They noticed, in a patient with a jejunal fistula, that when toast was eaten only a small amount of liquid material appeared at the fistula, but that when white bread was taken, large, doughy lumps as big as a pigeon's egg were passed.

The intolerance to white bread we consider to be the result of the distension of the hypotonic gastric musculature, which we believe to be the essential cause of rosacea. We noted delay in emptying in five of our fractional test-meals, and Eastwood[2] observed the same feature in many of her cases. Eastwood concluded from her radiographic studies in rosacea that gastric hypotonicity was common although not universal. We have also noted that, in two cases of hyperchlorhydria and in one case of normal acidity, both the rosacea and the indigestion were relieved by 30 minims of dilute hydrochloric acid by mouth. This suggests that the benefit of acid therapy lies not in the fact that it is a substitute

With these views in mind we have studied 40 cases of rosacea during the past year, taking careful histories in each. On the assumption that the gastric fault is the prime factor, we investigated these patients not only by means of fractional test-meals but also by a small series of histamine test-meals, correlating our results with the results of treatment and with the findings on physical examination. Of our 40 cases, 33 were women. The ages of onset ranged from 18 to 68, but the majority of the ages of onset lay around 35 years. Most of the women were married and had had children; many of them had those two curious and well-known findings in rosacea—low blood pressure and cold extremities.

CIRCULATORY DISORDERS

Rosaceous patients tend to have cold hands and feet, often accompanied, in the female sufferers, by "dead" or "white" fingers. The latter is a phenomenon related to Raynaud's disease. Exposure to cold induces whiteness or numbness; as the circulation recovers the fingers become blue or cyanotic before resuming their normal colour. The phenomenon may last a few minutes. "Bad peripheral circulation" has been noted by MacLeod [6] in these patients but, although it is common in rosacea, it is not invariable. "White fingers" occur frequently in non-rosaceous women and in some non-rosaceous asthenic men. A poor peripheral circulation may be found in rosaceous subjects with normal systolic blood pressures or with low pressures. It may also exist in those with hyperchlorhydria and those with hypochlorhydria. As far as we observed, the white fingers and cold extremities go on even when the rosacea and the indigestion are materially improved.

We examined the nail fold of a few of these patients under the capillary microscope. There appears often to be a marked dilatation and even tortuosity of the venous side of the capillary loops. Often, too, there was a terminal "knob" or aneurysm on the convexity of the loop. These changes seem to occur in the winter and to disappear in the summer, but we have made too few observations to do anything more than mention these results. During the winter there is a small exudation of serum from the skin capillaries of the hands of these patients, and this gives the skin of the hands a slight thickening, especially over the knuckle folds of the proximal interphalangeal joints. On the whole, the bad peripheral circulation seems more a background to the disease than the disease itself, but it is undoubtedly of some importance in the ætiology, for it is observed more often in rosacea than in most skin diseases.

As is well known, about a quarter of the cases of rosacea have a low systolic blood pressure for their ages. The lowest systolic blood pressure in our series was 100 mm. Hg. Low blood pressure is, however, not an essential feature of rosacea; indeed, we have notes of one case with a systolic pressure of 180 and of another with one of 200. The blood pressure bore no relation to the gastric acidity or to the severity of the rosacea in our series; neither did the presence or degree of the coldness of the extremities bear any relation to the severity of the rosacea, the gastric acidity, or the blood pressure.

SEXUAL AND ENDOCRINE FACTORS

Dysmenorrhœa was conspicuous by its absence in our series. One patient did complain of a "terrible" pain at the periods, but her neurotic nature made us suspect her statement. The following menstrual irregularities were noted: oligomenorrhœa, 2 cases; irregular periods, 1 case; imperforate hymen, 1 case.

The premenstrual exacerbation of rosacea is an interesting subject for speculation. One observant mother told us that her daughter's rosacea began to get worse 14 days before the monthly period, and was at its worst a day or two before the period began; there was amelioration during the actual period. Now, those cases of rosacea which get well with treatment—say with hydrochloric acid—no longer experience any exacerbation during the premenstruum. It is reasonable to assume, therefore, that the action of the premenstruum is to aggravate the gastric fault in most cases and that the premenstruum is without influence when the gastric fault is removed or corrected. If this were not so, and were the action of the premenstruum independent of the gastric factor, one would expect its action to persist after the gastric fault had been corrected.

In some of the irregular bleedings that occur round about the menopause the face is worse with the uterine loss. Why this is so is obscure. Some of the irregular and excessive bleedings of the menopause are associated with cystic follicular ovaries with an excessive formation of œstrin. It is possible that the connexion may be in this factor.

We treated three patients (one a young girl) with injections of ovarian follicular hormone. We used both Theelin (P. D. & Co.) and Oestroform (B.D.H.). The former we administered in bi-weekly doses of 50 rat units and the latter in bi-weekly doses of 1000 and 2000 B.D.H. units. The treatment, in two cases, was supplemented by oral administration of Oestroform tablets and was continued for three weeks. Although we provoked menstrual bleeding in one case previously amenorrhœic, we noted no improvement in the rosacea on this treatment; indeed, after the cessation of treatment, two of the cases seemed to settle down to a natural recovery.

In very many cases of "menopausal rosacea" there has been indigestion for a great many years before the menopause, and the latter seems to act more in the nature of "the last straw" than as a direct cause of the rosacea. It is probable that the menopause merely aggravates the gastric fault and is therefore quite a secondary matter. In three cases we noted that, although indigestion had been present for ten and even twenty years, it was the advent of the climacteric which precipitated the rosacea. In this type of case the rosacea usually begins before the periods have ceased.

EYE DISEASES AND OTHER CONDITIONS ASSOCIATED WITH ROSACEA

The usual ocular lesions are: (1) dilatation of the conjunctival vessels—i.e., rosacea of the conjunctiva; (2) rosaceous phlyctenular conjunctivitis, usually seen on the margin of the limbus and resulting in a leash of conjunctival vessels leading to the phlyctenules; (3) corneal ulceration resulting from the breaking down of the phlyctenules; (4) meibomian cysts; and (5) keratitis. In our series 6 cases had eye lesions, which were as follows: "eyes have been inflamed"—meibomian cyst (1 case); rosaceous phlyctenular conjunctivitis (1 case); corneal ulcer (3 cases); corneal ulcer and phlyctenular conjunctivitis (1 case).

If the face and indigestion respond to treatment the eyes will usually follow suit, but where there is long-standing corneal ulceration the issue is not so simple. One patient had a deep and active corneal ulcer on the right eye, while on the left eye there was simple dilatation of the ocular and palpebral conjunctival vessels. This dilatation was made much worse with acid (as were the dyspepsia and the rosacea) but had practically gone after four days on a bismuth and soda mixture alone, which suited his indigestion and rosacea equally well. Of the six rosaceous patients with ocular lesions, five were women and one was a man.

The eye lesions are possibly of the same nature as those on the face; it is unlikely that they are embolic in origin, as in tuberculous phlyctenular conjunctivitis. The rosaceous phlyctenules, on section, are said to be a collection of round cells. The most probable explanation is that the process is a low-grade pyogenic infection. Apparently the meibomian cyst is not a true cyst but more in the nature of a low-grade chronic inflammatory reaction. The eye lesions usually occur after the rosacea develops, but in two of our series the eyes were affected first. The associated diseases which came to light in the course of the case-histories while we were searching for any possible common factor in our series were very various.

1. Acne vulgaris (3); a history of acne was obtained in one case. Acne scars are rare in these rosaceous patients; in most cases the complexion has been good until the advent of the rosacea.
2. ? Subacute appendicitis (1); recent operation for acute appendicitis (1).
3. Migraine (2).
4. Recent pleurisy with effusion (1); tuberculous peritonitis in childhood (1).
5. Rodent ulcer (nose) (1).
6. Psoriasis (1).
7. Diabetes (1).
8. Hypothyroidism (1).
9. Alopecia areata (1).
10. Cystic cavity in scaphoid (1).
11. Rheumatism and vague history of chorea (1).
12. Vague fibrositis (2).
13. Osteo-arthritis (5), most of them being of the climacteric type.
14. "Rheumatism in fingers and ankles" (1).
15. Hypertrichosis (2).

TEST-MEALS

Fractional test-meals were done in 14 cases and the results were as follows:—

	Cases.
1. Practically complete achlorhydria	1
2. Hypochlorhydria	2
3. Low normal acid	2
4. Normal acid	4
5. Hyperchlorhydria	4
6. Climbing HCl	1

Two cases of hyperchlorhydria, one case of climbing acid, one normal acid curve, and one low acid curve had delay in emptying. Excessive mucus was present in only one case—that which was almost achlorhydric. In no case amongst those with low acidity was the latter explicable by early duodenal regurgitation, as judged by the presence of bile.

Eleven histamine test-meals were given, including three cases which had previously had the ordinary fractional meal. These three cases, as judged by the ordinary meal, had hyperchlorhydria, normal acidity, and low normal acidity respectively. It was thought that the administration of the histamine for the purpose of extending our knowledge of the gastric fault in rosacea would also allow us to study the effect of the drug on the flushing of these patients. Ergamine acid phosphate, 1 mg., was injected under the skin of the forearm. The flush developed in four minutes in the rosaceous areas and then spread all over the face and neck, being accompanied by a throbbing headache. In women, a blotchy redness developed over the neck and upper part of the chest more or less concurrently with the rosaceous flush, until finally the whole exposed part of the head and neck was involved, down to the V-shaped "blouse area." The flush persisted from one-quarter to three-quarters of an hour, and always lingered in the atonic dilated capillaries of the rosaceous area, although it had faded elsewhere. Only one patient, who had hyperchlorhydria by fractional test-meal, did not flush at all with histamine.

The test-meal findings, both histamine and fractional, were, as far as they went, such as would be found in an unselected group of normal individuals of the same age-period. There is therefore very little evidence of any fault in gastric secretion in most cases.

It will be seen that our fractional test-meals (14 cases) gave only one case of achlorhydria—i.e., 7 per cent. Brown[2] found 14 per cent. and Eastwood 8 per cent. achlorhydria in their series of rosaceous patients. Dahl-Iverson, quoted by Connor,[7] gave the following figures for test-meals in normal subjects:—

Age.	Subjects.	Achlorhydria %.
20–30	16	—
30–40	46	9·0
40–50	29	3·5
50–60	26	19·0
60–70	11	37·0

In a review of 3381 fractional test-meals on patients with normal gastro-intestinal tracts, Vanzant, Alvarez, Easterman, Dunn, and Berkson[8] found that achlorhydria increased with age, rising from 4 per cent. at the age of 20 to 26 per cent. at 60, the average incidence being 12·1 per cent. It was further observed that females were more liable to achlorhydria than males. Apperley and Semmens[9] found achlorhydria in 30 per cent. of healthy female students.

The above figures show that in rosacea there is no appreciable departure from the normal in the incidence of achlorhydria, and the latter can be taken as a much better guide to gastric secretory dysfunction than mere subacidity, which is, according to some observers, a common finding in any group of women.

We conclude, therefore, that there is no real evidence of any constant abnormality in the gastric secretion of rosaceous patients. That there is not an active gastritis is suggested by the symptoms, for rarely is there pain or irritation from eating meat, fruit, pips, rough vegetables, or any other foods which would irritate an inflamed surface. Further, the indigestion can continue for as long as ten years without alteration in the test-meal.

GASTRIC TONE

The two things that rosaceous patients cannot tolerate are white bread and very heavy meals. Although white bread is badly tolerated, toasted brown bread is usually well borne. In this connexion the observations of Lehman and Gibson[10] are interesting. They noticed, in a patient with a jejunal fistula, that when toast was eaten only a small amount of liquid material appeared at the fistula, but that when white bread was taken, large, doughy lumps as big as a pigeon's egg were passed.

The intolerance to white bread we consider to be the result of the distension of the hypotonic gastric musculature, which we believe to be the essential cause of rosacea. We noted delay in emptying in five of our fractional test-meals, and Eastwood[3] observed the same feature in many of her cases. Eastwood concluded from her radiographic studies in rosacea that gastric hypotonicity was common although not universal. We have also noted that, in two cases of hyperchlorhydria and in one case of normal acidity, both the rosacea and the indigestion were relieved by 30 minims of dilute hydrochloric acid by mouth. This suggests that the benefit of acid therapy lies not in the fact that it is a substitute for missing acid, but that it stimulates gastric tone and peristalsis.

Wingate Todd,[11] experimenting with several hundreds of normal students by means of gastric radiography, found that gastric peristalsis was stimulated by lactic acid, buttermilk, alkalis, and tincture of peppermint. The effect of these was well marked, and peristalsis was slow, regular, and deep. Now the sensation in any hollow, muscular organ is an expression of the tension in its muscular coat, and if that organ is hypotonic—as the stomach has often been shown to be in rosacea—it would be much more likely to give expression to its "feelings" after meals heavy in total bulk or in carbohydrate content. This increase of tension in the gastric muscular wall is interpreted by the patient as a feeling of distension or "wind." That this sensation is not actually due to gas is demonstrated by the well-known observation that patients viewed under the fluorescent screen after a barium meal often complain of distension by wind when there is no obvious enlargement of the gastric air-bubble.

Not only does the stomach tend to be hypotonic in rosacea but so also are many of the other muscles, voluntary and involuntary. Barber and Ryle [1] noted the broad, flabby tongue; Rulison [12] observed the poor tone of the abdominal muscles; Eastwood [3] commented upon the low blood pressure; and many have found constipation. The entire absence of any dysmenorrhœa in these patients may depend upon a certain uterine hypotonus. That a large meal causes gastric discomfort in rosacea is in accordance with Wingate Todd's observation that a large barium meal inhibits peristalsis for some considerable time.

The rosaceous reflex must depend on increase of tension in the gastric muscle. Any factor which distends the stomach, which inhibits or flurries peristalsis, or which delays emptying, causes an increase of tension in the muscle and will call forth the rosaceous reflex in a predisposed subject. If this fact is accepted, many of the obscure associations of rosacea can be explained. It accounts for the painful conditions in the alimentary tract; it explains why adverse psychological influences, chronic illnesses, and the menopause can be causative factors.

Wingate Todd [11] noticed that prolonged anxiety caused complete inhibition of all gastric peristalsis and that at the same time there was marked hypotonicity. It is undoubted that painful intestinal or abdominal conditions and many general illnesses cause the same state of affairs. The same observer found feeble peristalsis and hypotonicity in female students during the premenstruum, and this phenomenon ceased when the flow was established. It is certain that anything which makes the indigestion worse will also increase the rosacea, and that the converse is also true. We regard this rosaceous reflex secondary to increased gastric tension as the primary factor in rosacea, for if the gastric neurosis is remedied neither the premenstruum nor any other factor has any influence in aggravating the rosacea. The adverse influence of these factors on the gastric musculature is counteracted by the therapeutic stimulation of the stomach by acids, alkalis, or carminatives; and good, slow peristalsis and good tone will relieve the tension of the stretched hypotonic muscle. Poulton and Stewart [13] have shown that the discomfort associated with distending the stomach by a compressible rubber bag is relieved momentarily when a wave of peristalsis takes the tension off the stretched nerve-endings in the gastric muscle. Similarly, when we give medicinal stomachics to a dyspeptic patient with rosacea, we are protecting the nerve-terminals in her gastric musculature by making her stomach achieve normal tone and good, deep peristalsis.

Of course, the normal reflex of slight increase of face temperature on taking hot fluids is naturally much exaggerated in the atonic capillaries of rosacea. The vasodilatory effect of alcohol and the nasal rubor of acute nasopharyngeal infections is similarly exaggerated in the rosaceous subject. The drinking of alcohol and tea (the latter regarded mainly as a hot fluid apart from a possible direct gastric irritant) therefore merely aggravates the normal reflex and cannot be regarded as a direct cause of rosacea.

Rulison's suggestion is probably correct, that the true place of gastric stimulants, such as mustard and curry, in rosacea is that such aids to digestion are needed by these patients and that unconsciously they are treating themselves. After all, therefore, the acids, alkalis, and carminatives which we administer are to these people merely very effective but rather unpalatable condiments. We provoke efficient gastric peristalsis and tone, and if the gastric acidity is not too high the best condiment appears to be 30 minims of dilute hydrochloric acid with meals; but if the acidity tends to be too high or normal, we run the risk in most cases of abolishing peristalsis and of making both the rosacea and the indigestion worse. This we have observed ourselves on many occasions. There are, however, a few patients with hyperchlorhydria (as we noted above) who can either rapidly dilute the excess acid, or perhaps neutralise it in some way, and in these cases the rosacea and the indigestion are benefited by acid therapy.

TREATMENT

The treatment of the malady is, then, obvious. The following adverse influences on gastric peristalsis should be looked for, and, if possible, remedied: (1) "nervous strain," by which one means any predisposing cause of a psychogenic nature; (2) painful abdominal conditions; and (3) chronic diseases or infections. As to diet, nothing but the avoidance of big meals, especially when taken under emotional stress, and of white bread, is necessary. The best bread to take is toasted brown bread. Luminal, bromides, and psychotherapy may have their uses in improving the all-important psychological factor. An adequate amount of post-prandial rest and exercises will remedy the tone of the muscles.

It is of value to have a test-meal done, in order to see whether the gastric acidity is too high to attempt giving 30 minims of dilute hydrochloric acid by mouth in water with meals. This should be tried, even if the gastric acidity is high, for a day or two. Otherwise peppermint, alkalis, or menthol are the best condiments to administer before meals.

Some patients recover if they are removed into better surroundings, or if their financial circumstances improve, but in a great many cases the provoking factor is irremediable, and has to be counteracted by nerve sedatives and medicinal stomachics. There should be great scope for psychotherapy in these patients.

SUMMARY

(1) The gastric acidity is practically within normal limits in rosacea, as demonstrated both by the ordinary fractional test-meal and by the histamine test-meal. (2) The rosaceous reflex is induced by an increase of tension in the stomach wall. (3) This increase of tension may be due to one or more of the following factors: (a) delay in emptying, (b) feeble peristalsis, (c) an easily distensible stomach due to hypotonia, (d) over-rapid peristalsis, and (e) gastric spasm. (4) The action of hydrochloric acid, alkalis, and carminatives in rosacea is to give slow,

deep, unflurried gastric peristalsis, and good muscular tone. The gastric tension is thereby relieved, the indigestion disappears, and the vasomotor reflex of rosaceous flushing depending on the tension is inhibited. (5) The gastric neurosis is due to many causes, amongst them being adverse psychological influences, poor general muscular tone, and reflex effects from disturbance in an abdominal viscus. In a few cases the reflex may be from a lesion in the gastric mucosa itself—i.e., gastritis or ulcer.

In conclusion we must express our indebtedness to Dr. Barber and Dr. Forman, both for their helpful suggestions and stimulation and for their permission to publish these observations on their patients. Our thanks, too, are due to Dr. L. J. Witts[14] for his expert advice on the histamine test-meals and on other points.

We are indebted to Parke, Davies and Co. and British Drug Houses for a generous supply of Theelin and Oestroform.

PSYCHOLOGICAL EFFECTS OF BODILY ILLNESS IN CHILDREN

BY DAVID FORSYTH, M.D., D.Sc., F.R.C.P. Lond.

CONSULTING PHYSICIAN TO CHARING CROSS HOSPITAL AND THE EVELINA HOSPITAL FOR CHILDREN, LONDON; LATE SENIOR PHYSICIAN TO THE PSYCHOLOGICAL CLINIC (MINISTRY OF PENSIONS)

THOUGH it is only to be expected that children, in keeping with their sensitiveness to early experiences, will be affected psychologically by bodily illness, this aspect of child psychology seems not to have been dealt with in any article or book. With adult patients, as every doctor knows, illness is often responsible for an exaggerated selfishness and an unmistakable childishness in their behaviour to those tending them. It remains to be generally recognised that the dispositions of sick and invalid children may be subtly and profoundly changed in ways which may persist after convalescence and even throughout life. But since these changes are usually gradual, and a child is hardly able to speak of them, they are not often understood by the parents and are rarely attributed by them to their real origin.

To glance first at the notions which children shape for themselves about illness. It is beyond them, of course, to formulate the explanation which science provides—e.g., that diseases are produced by germs—and their ideas pass through two stages. When very young they believe that illness, with its pain and discomfort, is caused by some living being in themselves—some horrid little man or animal, gnawing and biting at their insides. Later, and for a good many years, they regard illness as a punishment. This they suppose can only be in connexion with something wrong they have done, and their feelings of guilt come into close relation with their notions about illness. In these two levels of ideas may be recognised the stages in the evolution of primitive society: first, the animistic explanation of the universe, and later its religious interpretation, when illness is regarded as inflicted by God by way of punishment for evil living.

BRIEF ILLNESSES

A not unusual effect of a temporarily incapacitating illness is to retard a child's mental development, and even to produce in a younger child an obvious regression of character and intelligence. This is accounted for in part by its restricted activities, but also by certain features of a sick-room. By confinement to bed the child experiences anew the life with which it was familiar in its cot during its first years. Again, in sickness a child is permitted to do little or nothing for itself, and, being tended by its mother, readily slides back into the mental state of its early helpless years. Yet again, its diet is probably restricted to milk—its food during its first years—and this, too, helps in making it babyish again.

With briefer illnesses the retarded development may be noticeable only for a few weeks afterwards, but in others the psychological effects may be more lasting, and may continue even into adult life, for example when the illness has been accompanied by suffocative symptoms. These are always peculiarly terrifying to children, and may leave behind a morbid fear of suffocation. An attack of pneumonia may be the exciting cause, though a severe sore-throat or even adenoids, by obstructing the air-passages, is often responsible.

Another effect is to intensify the fear of death. Sick children readily become troubled by this fear, and this may explain otherwise perplexing details in their behaviour. In cases of heart disease especially the fear may grow to large proportions. Children with this disease seem to acquire early the knowledge that it is often fatal, even suddenly fatal, and their concern about themselves may be very real. Sometimes this information has come by reading, or it may have been imparted by another child; but often it is overheard by chance. Doctors themselves, in the remarks they let fall in a child's sick-room, do not always remember how alert a child's ears can be, and how readily a casual word may be picked up and become the source of a secret fear for years after. Not a few healthy adults who, as children, were the suspected subjects of heart disease, go about in fear of dropping dead, because of a whispered conversation, overheard or half-heard, between doctor and mother.

An interesting effect of illness to be noted in "nervy" children is that not a few of them are speedily relieved of their neurotic symptoms when confined to bed. These are the cases in which the nervous trouble is bound up with jealousy of a brother or sister in the mother's affection. Illness secures to the invalid something of a monopoly of the mother's care and attention; for the time being the jealousy is allayed, and with it the nervous symptoms.

Psychological changes may also follow a surgical operation. All too often children are operated on without a word of preliminary explanation, even from those they trust. Indeed parents and others may conspire to keep a child in ignorance; or, worse, will deceive it by lies. The experience is usually neither forgotten nor forgiven by the child. It feels betrayed by those whom it loves best, and henceforth a barrier of mistrust is likely to stand between it and its parents. Another common effect of an operation is to leave a child frightened, even terrified, not only about doctors but in its everyday life also. Many a child has had its normal, happy self-confidence permanently changed to fear and timidity after taking part in a "field-day" at a hospital throat department, where tonsils are removed wholesale in a scene of blood with children crying and vomiting all round. Or again, to operate without an anæsthetic, in the mistaken belief that a child feels little and notices less, has often been the occasion of a deep-going emotional shock. On the other hand, an anæsthetic given unskilfully may make a child think it is being deliberately suffocated, and the terrifying effects may be lasting. The dread of anæsthetics felt by many adults may sometimes be traceable to a single experience of this sort in childhood.

In cases of accident children are quick to fear that they are going to die. Without a prompt word of reassurance from doctor or relative, they may be left with an exaggerated fear of death; and this for years to come may baulk them in many of their activities, including school games which involve any risk to wind or limb. On the other hand, a minor accident may be as enjoyable to a child as a minor illness. A boy, for example, with a hurt hand or head, who has to wear a bandage which others can see, may feel as happy and proud as a national hero. Nevertheless, the psychological shock following a serious accident may be deep and lasting, as the following example shows.

> Perhaps the severest civilian case of shattered nerves in my experience is that of a man in his twenties who shook incessantly from head to foot; he lacked self-confidence, avoided all social relations, and shunned every responsibility. A thin scar across his neck from side to side helped to elicit the history of the event that shattered his nerves. He was an only child, and one night when he was about eight his mother, a widow, committed suicide, having first come to him asleep in his room and attempted to kill him by cutting his throat. Any more devastating experience for a child could hardly be imagined, for, apart from tragically losing his surviving parent and in addition to his attempted murder, he lived to realise that it was the one he loved best in the world who had intended his death.

When convalescence begins after an acute illness children are often irritable. This is an expression of ennui felt by a child whose energy is returning faster than the restrictions on its activities are relaxed; and once the child is up and about the irritability soon goes. Most children are glad and eager to resume an active life, but some really enjoy being ill—once the worst is over—and may be little disposed to hasten their convalescence. The outstanding advantage in prolonging their recovery is to continue, if at home, to preoccupy their mother's attention to the exclusion of the rest of the family, and if in hospital, to be spoiled by the nurses.

CHRONIC AFFECTIONS

It is in chronic infirmities of any kind that the most insidious and deep-going effects may be traced, so considerable is the interference with a child's normal daily life. Common examples of these chronic conditions are infantile paralysis, depriving the child of the use of one or more limbs; heart disease, severely handicapping its activity; congenital deformities like club-foot; and the crippling tuberculous disease of joints or spine which entails confinement to bed for perhaps months or years. In addition, facial disfigurements, such as congenital nævus (port-wine stain), hare-lip, and squint, by being noticeable by everybody, often react on a child's mentality; while even defective sight, when glasses are worn, may have a similar psychological effect. Any child with a chronic disability feels first and foremost that he is different from other children. He sees himself as in some way marked off from them, and of course his life may actually be solitary. Moreover, enforced inactivity may always be there to make him realise that he is not as others.

Of all the harmful effects perhaps the most frequent is an inferiority complex. This arises partly from the fact of the disability itself, which tells the child beyond any question that he is inferior in certain respects to other children; but even more it takes origin in his sense of guilt, and his line of argument seems to be the following. Illness is a punishment for wrongdoing and sin. Since then he is being punished in this way, he believes he must be wicked, though just what his sin is he has little idea. The acceptance of the belief, however, leads to mental depression, usually with periods of remorse in which he fervently wishes he could undo his offence. Nevertheless, alongside this runs another line of thought, when he assures himself that he is innocent of any wrongdoing. As the next step he begins to feel he has been punished unjustly, and regards himself as the innocent victim of the world around him. His hostility is roused against God and especially against his parents. His feelings against the latter become all the intenser when he reflects that it is to them that he is entitled to look for protection, and that, by having failed to safeguard him against his physical disability, they have served him very badly indeed. He comes to blame them for his infirmity, and as he settles to a more or less sustained antagonism, the whole atmosphere at home is changed. And yet, as he is almost certainly unable to put his grievance into words, his parents are little likely to be able to do anything to remedy the unhappy situation. Much more probably their own unfriendliness will be stirred against their tiresome, provocative child. In the end, and most damaging of all, he is driven to the conclusion that on account of his wrongdoing he has become unlovable by his parents; and nothing so undermines a child's self-confidence as the belief that he is unworthy of love.*

REACTION OF SUPERIORITY TO INFERIORITY

An inferiority complex may come to be replaced by a superiority complex. We know that some traits of character arise as "reactions" to existing traits of the contrary kind. For example, the feeling of sympathy, which is lacking in very young children, appears later as a reaction to the impulse of cruelty which is implanted even in infants; or there is the well-known instance of the Athenian, Demosthenes, who grew up with a bad stammer but became the greatest orator in ancient times. Similarly a child with an inferiority complex may later develop a superiority complex, endeavouring in this way to bolster up his self-confidence by hiding his inferiority under a show of loud and perhaps aggressive superiority. A similar reaction to a physical handicap may of course be widely seen in adults who are undersized (dwarfs especially), misshapen, or very ugly. With these the feelings of superiority often take the form of obvious conceit.

Another common harmful effect is a supersensitiveness to a physical defect, especially one like a club-foot or a birth-mark on the face, that can readily be noticed by others. Byron the poet was born with a club-foot to which he grew up so sensitive that even at the height of his fame he would not willingly have it noticed; and at social gatherings he would arrive early and take up his position in the room, so that the other guests might not see him limp. Not all children, however, are sensitive in this way, and young men with club-foot are known to me who are troubled by it not at all. Equally I have known two young women whose faces were disfigured by birth-marks; one of them had grown so sensitive about it that she avoided social relations and went out only after dark, while the other contentedly followed an everyday life.

---

* And, let it also be said, nothing so ensures a child's self-confidence as the knowledge, sustained by a not too infrequent expression of the fact, that he is loved by his parents.

It seems, therefore, that the deformity itself cannot be responsible for supersensitiveness, and that for the explanation we must look deeper. The psychological reaction in these cases depends on the child's sense of guilt. If this is exaggerated, it readily attaches itself to the idea of a bodily defect, and the child grows morbidly sensitive about it. These feelings of guilt are held to originate in an over-strict unbringing by the parents in the earliest years, especially in the matter of masturbation. Though this is a natural habit in children, the more they are shamed about it by their parents the stronger becomes their sense of guilt.

Invalidism may be responsible for undue selfishness, perhaps associated with self-assertiveness, in a child who has been pampered on account of ill-health. Such children when they grow up must share the fate of all egoists, and suffer many a hurt to their feelings from a seemingly unkind world. Similarly, self-pity may result from invalidism. As a form of masochism, it is a normal ingredient in child character and is often, of course, to be recognised in adults; but the intensification of it in a child as a result of illness, and especially of numerous illnesses, is generally attributable to mishandling by too sympathetic parents.

Yet another harmful reaction is jealousy directed against children who are fortunate enough to be sound in health. This, too, may lead to a sense of grievance which tends to set the child against the whole world. This embitterment on the one side is only too likely to provoke hostile feelings in the other members of the family, and things may go from bad to worse. Again, the position that is now brought about is that in which the child perceives that it is not loved, and it retaliates by indulging in deliberate naughtiness in the hope of annoying its parents—the situation which must have been in Shakespeare's mind when he made the hunchback Richard III threaten, "Since I cannot prove a lover . . . I am determined to prove a villain." By the time a child has settled down to prove itself a villain in its parents' eyes it has said good-bye to its happiness, and it may well grow up to display the same disagreeable character to the world in general. Not a little of the gratuitous offensiveness, and even worse, that is met with in adult life originates in this childhood experience of not being loved.

Even a child who is strong and healthy may easily become convinced to the contrary if he has a mother of the fussing type. Such a mother is for ever worrying and taking precautions lest her child should fall ill, until in the end the child is unable to believe that he is any but a poor creature to be shielded from the ruder blasts of life. Many of the healthy men and women who are convinced that they are "delicate," and accordingly plan their daily lives on semi-invalid lines, owe their erroneous belief to mothers of this kind.

This point is well illustrated in the following incident. A mother brought her girl of three—an only child—to me with a covering letter from her doctor saying that though he had repeatedly been called to see the child he had never detected anything amiss, and as the mother seemed dissatisfied on this account they had agreed to take a specialist's opinion. My examination equally disclosed nothing wrong, physically or psychologically; the child in fact was an exceptionally fine specimen, and one of whom any parent might well be proud. But on my breaking this news to the mother, her instant rejoinder was, "Oh, but how dreadful! I'll have nothing to worry about."

Not all mothers, however, fuss over their children, even the sick ones. There is a sort of mother who firmly makes it her business to discourage "going sick" as a weakness, if not a crime, and in her Spartan home a child hardly dares to speak of its genuine aches and pains.

SECONDARY GAIN

A very familiar aspect of neurotic illnesses in adults is known as "secondary gain": it is the utilisation by neurotics of their nervous disabilities in order to gain some advantage for themselves, such as evading disagreeable duties. The motive is also to be found in children. One child uses its physical disability to secure an extra share of parental affection, especially in rivalry with any brothers and sisters. Another endeavours—often successfully—to make itself the centre of family importance. Another, again, turning its disability to selfish ends, tries to get its own way by playing on its mother's feelings with a threat of another attack of its symptoms, whatever they may be, unless it is given in to. In this way it not infrequently succeeds in dominating her altogether. Yet another manifestation of this secondary gain is, as with adults, in escaping unpleasant tasks such as going to church or to school.

Finally, not all the effects of invalidism are necessarily harmful, and a few of them can fairly be entered on the credit side. For example, a child with some lasting disability, gradually realising that neither cure nor relief is possible, may develop an exceptional fortitude of character which is likely to be an asset to it in later life. Again, physical inactivity tends to make a child indulge unduly in phantasying—a habit which, though it favours the development of a dreamy and unpractical nature, also provides exceptional opportunity for ambitious phantasies; and these may remain as a powerful driving force behind its adult enterprises. The association of physical inactivity with phantasying favours also the growth of the contemplative faculties, with an outcome that may sometimes be seen in the later choice of a vocation such as authorship or art.

THE ATTITUDE OF PARENTS AND TEACHERS

This brief survey would be incomplete without recognising that the subject has another side—namely, the emotional reactions of adults themselves to bodily infirmity in children. The usual effect in parents is to quicken their sympathies and so increase their love and concern for their infirm child. The risks inherent in this have already been indicated. In other parents, however, the reaction is one of disappointment that a child of theirs should be physically unsound. Their self-esteem is hurt, and they become, if only unconsciously, ashamed of their offspring, and treat it accordingly. Sometimes this disappointment leads to an active dislike of the child. As part reason for this there may be the expenses of the child's illness, entailing personal sacrifices by the parents; but in addition their sadism is likely to be provoked, and their attitude to the child is one of unkindness or even cruelty. Yet another reaction of the parents may often be noted in cases of congenital deformity. Many parents unconsciously regard a deformity of this kind as a reflection on themselves; their sense of guilt is stirred, and they may even hide away their child from sight of neighbours, doctors, and others.

School teachers also show emotional reactions to an infirm child. In fact no teacher is without a response of some kind, usually of sympathy or antipathy. An exaggerated sympathy is probably more characteristic of the woman teacher, and an unreasonable dislike of the man teacher. An infirm child, therefore, will hardly encounter in its classroom an ordinary emotional atmosphere. Add to this that schoolmates, boys especially, are notoriously intolerant of physical infirmity, which they are apt to treat with contempt and jeers.

Neither at home, then, nor at school, is an infirm child likely to experience the normal emotional environment which is needed for normal psychological development.

THREE CASES OF
TUBERCULOSIS OF THE CENTRAL NERVOUS SYSTEM IN CHILDREN
APPARENT CLINICAL RECOVERY

By Agnes R. MacGregor, M.B., F.R.C.P. Edin.
LECTURER ON PATHOLOGY OF DISEASES OF CHILDREN, UNIVERSITY OF EDINBURGH; PATHOLOGIST TO THE ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN

H. J. R. Kirkpatrick, M.B., D.P.H.
LECTURER IN BACTERIOLOGY IN THE UNIVERSITY; AND

W. S. Craig, M.D., M.R.C.P. Edin.
ASSISTANT TO THE PROFESSOR OF CHILD LIFE AND HEALTH IN THE UNIVERSITY

In the course of an investigation of cases of tuberculous meningitis and glandular tuberculosis, which is being carried out on material available in the Royal Edinburgh Hospital for Sick Children and other Edinburgh hospitals, three cases have been observed which indicate that active tuberculous infection of the central nervous system, associated with the presence of tubercle bacilli in the cerebro-spinal fluid, does not necessarily proceed immediately to progressive and fatal tuberculous meningitis. Tubercle bacilli were isolated from cerebro-spinal fluid of these patients, while their subsequent history suggests that the lesion in the nervous system has been at least temporarily arrested.

Examinations are being made of specimens of cerebro-spinal fluid obtained not only from cases in which the clinical diagnosis of tuberculous meningitis is established, but also from patients who show only slight clinical evidence suggestive of an intracranial lesion with, in addition, a positive reaction to the tuberculin test. In the routine bacteriological examination, each specimen of cerebro-spinal fluid is injected subcutaneously into the groin of one or more guinea-pigs, and from one to three months later the animals are killed and examined for the presence of tuberculous lesions. If an animal is infected, differential media are inoculated with material obtained from the regional lymph glands draining the area injected.

In the three cases recorded in this paper, injection of cerebro-spinal fluid led to infection of the guinea-pigs by the tubercle bacillus. Culturally the following characteristics were noted: (*a*) In Cases 1 and 3 the growth was of the dysgonic type, indicating infection by the bovine type of tubercle bacillus. (*b*) In Case 2 the growth was of the eugonic type, indicating infection by the human type of tubercle bacillus.

CASE RECORDS

Case 1.—A. B., aged 1 year and 7 months, was admitted to the Royal Hospital for Sick Children as a case of acute pleurisy. There was a history of cough, fever, and lassitude for eight days, and heavy breathing for three days. Vomiting occurred on the evening of onset of the illness but on no subsequent occasion. His only previous illness was measles at the age of 10 months. At the time of admission the child was in a weak undernourished state, uttered frequent cries, and continually rocked his head as if in pain. The fontanelle was small but tense. Pupils were equal and widely dilated. The Kernig reactions were negative, and there was no nuchal rigidity and no tâche cérébrale. Both ear-drums were red and bulging. Marked percussion note dullness with diminution of breath sounds and vocal resonance were noted at the left base, and aspiration was attempted without result.

The day after admission lumbar puncture was carried out, and water-clear cerebro-spinal fluid obtained under increased pressure. On microscopical examination of the fluid no tubercle bacilli or other organisms were found. There was no increase in cells, and biochemical analysis gave the following results: total protein, 40 mg. per 100 c.cm.; chlorides, 700 mg.; sugar, 0·060 per cent.; gold test, no precipitate.

After lumbar puncture there was some improvement in the child's condition, and the temperature, which had varied between 101·2° F. and 102·8° F. since admission, fell on the third day (March 25th) to 98° F. On March 29th the restlessness which had always been a feature became worse, and was associated with a rise in temperature. Paracentesis of the right ear-drum was performed with resultant relief and return of the temperature to normal. The patient was sent home on April 3rd. Three weeks later, on April 24th, he was readmitted on account of marked respiratory distress. The physical signs in the chest were similar to those found on March 23rd, except that there were in addition fine crepitations at both bases. The knee-jerks were diminished, the abdominal reflexes absent, and there was resistance to flexion of the neck. The child was very restless and continually holding his head in his hands. The tuberculin skin test was positive. At the time of readmission the temperature was 103° F., and it continued to swing between 98° F. and 103° F. for five days. Paracentesis of the left ear-drum was carried out on April 29th, blood and pus being obtained, after which the temperature settled and the child's condition greatly improved. The boy was kept in hospital a further week and discharged in good health on May 8th, 1933.

The child was visited in his home on Jan. 17th, 1934, eight months after discharge. He showed signs of bony rickets associated with a moderate pallor and laxity of the ligaments. The abdomen was prominent, but this appeared to be part of the rickets. Since his discharge from hospital the previous May the child had had several colds but otherwise progress had been uneventful.

Case 2.—C. D., a boy aged 2 years 3 months, was admitted to hospital on April 17th, 1933. His only previous illness had been measles in April of the previous year. There was no history of disease in the family, and the housing conditions were good. Five days before admission the boy vomited but appeared to have completely recovered within an hour. Two days later vomiting again occurred and was accompanied by fever and loss of appetite, and the child kept his head held in his hands, as though in pain. Next day (April 15th) he was unable to stand on account of "weakness in the legs." On the 16th he lost the power of his right arm but regained this by the evening. He was extremely irritable during examination following admission to hospital. He appeared to suffer discomfort on palpation of the neck and kept his head inclined to the right side. There was slight resistance to flexion of the neck. A flaccid paresis of the right leg was present associated with loss of tendon reflexes. The knee- and ankle-jerks were diminished on the left side. Plantar responses were both flexor, and the Kernig tests gave negative results. There was no weakness of either arm.

On April 19th flaccid paresis of the right leg and slight neck rigidity were still present and lumbar puncture was carried out; 50 c.cm. of clear cerebro-spinal fluid were withdrawn under pressure. A small coagulum formed in the fluid on standing. A cell count gave 130 per c.mm., and lymphocytes were in excess of polymorphonuclear cells. No organisms were found on microscopic examination. Biochemical analysis of the fluid gave: total protein, 80 mg. per 100 c.cm.; chlorides, 643 mg.; sugar, 0·132 per cent.; gold test, no precipitate.

On April 21st the temperature was 97·4° F., and remained at this level for three weeks after varying between 97° F. and 99·4° F. during the first four days in hospital. By the 24th neck rigidity had disappeared but the boy still remained abnormally irritable for two weeks after admission. During the patient's fifth week in hospital the temperature showed a slight tendency to irregularity, on one occasion rising to 99° F. About this time the pulse-rate became more rapid, and there was a slight loss in weight. Pulse and temperature settled and the patient was discharged to Challenger Lodge as a case of poliomyelitis on July 6th with paresis of the right leg still present.

The boy was seen on Jan. 21st, 1934, six months after discharge. There was considerable wasting of all the muscles of the right thigh and leg, but limited voluntary flexion and extension at the ankle-, knee-, and hip-joints could be carried out. Knee- and ankle-jerks on the paralysed side were absent; on the left side they were noticeably increased. The plantar responses were both flexor and both Kernig reactions were negative. Nothing else of note was found on examination. The boy was able to move about with the aid of a splint and his general health was good.

CASE 3.—E. F., a girl aged 4 years and 6 months, was admitted to hospital on August 3rd, 1933. Ten days previously she had been involved in a motor accident receiving injuries to the legs and left hand; she was not rendered unconscious, and when treated for her injuries nothing was found to suggest the presence of intracranial damage. She appeared to be in normal health until the sixth day after the accident when she was noticed by her mother to be drowsy. The same day (July 30th) she was incontinent. The drowsiness persisted to the time of admission. Throughout the day of July 31st she complained of a severe headache which disappeared by the evening and did not return. On the night of August 2nd she complained of pains in the back and right side, became delirious, and ran a temperature of 104° F. At the time of admission the child was lethargic and the temperature was 100° F. The next day she was more drowsy and irritable during examination; 10 c.cm. of clear cerebro-spinal fluid under slight increase of pressure were obtained by lumbar puncture. The fluid showed no increase in cells, and no tubercle bacilli or other organisms were found in it microscopically. Biochemical tests of the fluid gave the following results: total protein, 50 mg. per 100 c.cm.; chlorides, 720 mg.; sugar, 0·07 per cent.; gold test, no precipitate.

The day after lumbar puncture the child's condition began to improve; the improvement was maintained and she was discharged from hospital on August 12th after examination had eliminated the possibility of a cranial lesion. Next day she had a severe fit at home which lasted fifteen minutes and was associated with twitching of the right side of the face, right arm, and leg. She was troubled with retching after the fit and remained drowsy for the rest of the evening. She was readmitted to hospital the following day (August 14th) and the same evening had a severe fit, this being followed by vomiting and prolonged drowsiness. Two days later the girl was allowed up, and up to the time of discharge on August 24th was extremely active. Beyond a slight rise in temperature following the fit she was afebrile during the time in hospital after readmission. The tuberculin skin test was positive. The exact nature of the condition was not determined but a tentative diagnosis of epilepsy was made.

On Jan. 17th the girl was seen in her home, five months after discharge. Since leaving hospital she had continued to make uninterrupted progress and when seen was in excellent health. Her previous health is of interest. Between the ages of two and three years she had whooping-cough, chicken-pox, and German measles. At the age of three and a half years she had three severe fits all involving the right side which were never satisfactorily explained and which did not recur. The girl comes of a family known to be tuberculous. She is the second youngest of ten children, two of whom died at the age of six months, one following pneumonia and the other from tuberculous meningitis. Of those alive one sister suffers from abdominal tuberculosis and a brother and sister from pulmonary infection. The father also is tuberculous.

COMMENT

Recovery from tuberculous meningitis, though extremely rare, is not unknown. In a careful review Cramer and Bickel [1] collected 46 cases, including one of their own, which were confirmed either by demonstration of *Bacillus tuberculosis* in the cerebro-spinal fluid or by production of tuberculosis in guinea-pigs by injection of cerebro-spinal fluid, the latter test being positive in 20 cases. In many of these recovery was temporary, and death followed within a few months from recurrence of meningitis or from the effects of tuberculosis elsewhere. In some, permanent sequelæ remained. Martin [2] collected 20 undoubted cases reported since 1894.

All these seem to have presented fairly definite clinical evidence of tuberculous meningitis, though Cramer and Bickel mention three cases in which the symptoms were abortive; and Martin suggests that recoveries are possibly more frequent than has been believed, and that very mild cases which result in recovery may pass unrecognised.

Those in our series are remarkable for: the absence of the classical evidences of meningitis; the extreme mildness and transience of such nervous symptoms and signs as existed; the absence in two of the three of any definite chemical or cytological change in the cerebro-spinal fluid; and the absence in the same two of any sequelæ up to the present time. None of the three was, in fact, at the time of the attack, thought to be suffering from meningitis at all. They seem, therefore, to fall into a somewhat different category from previously reported cases of recovery from tuberculous meningitis. We believe that the proved occurrence of such cases as these may throw new light on the problem of the pathogenesis of tuberculous meningitis.

In an important paper on this subject Rich and McCordock [3] published evidence from which they concluded that the prevalent teaching—that tuberculous meningitis is part of a general miliary (blood-spread) infection—is incorrect. They claimed that careful examination of the brain will show in practically every case that the meninges have been infected from an older focus in the vicinity, most often in the brain substance, from which tubercle bacilli have escaped in large numbers into the subarachnoid space. They contend further that the diffuse exudative reaction characteristic of meningitis can occur only if there be introduced into the subarachnoid space a number of bacilli in excess of what is likely as a result of even the most severe miliary tuberculosis. They support these contentions by evidence from experiment and from human cases after death.

If this view be correct it follows that a patient who develops tuberculous meningitis has, at some previous time, suffered an infection of his central nervous system by tubercle bacilli, which have set up a localised lesion—probably a caseous nodule (tuberculoma) superficially placed in the brain substance, or a circumscribed caseous focus in the meninges (meningeal plaque). It seems probable that the occurrence of this initial infection might in some instances be marked by clinical evidence, probably slight and transient, of a pathological process within the central nervous system. It is in the hope of obtaining some further light on this problem that we are including in our investigation specimens of cerebro-spinal fluid from children, such as these three, in whom the tuberculin test is positive and who present clinical evidence of meningeal irritation or other nervous lesions, but in whom tuberculous meningitis in the clinical sense is not present and does not develop during the child's stay in hospital.

We are as yet unable to offer proof that this suggested explanation of the facts here recorded is correct and that these incidents in the patients' histories coincided with the setting up of circumscribed lesions in brain or meninges, which may eventually cause meningitis. The subsequent history of these children will be of much interest.

One conclusion, however, seems clear. In the light of the facts recorded it is necessary to recognise that any clinical evidence of meningeal irritation or cerebral lesion, no matter how slight and transient, in a patient in whom the tuberculin reaction is positive, may be an indication of tuberculous infection of the central nervous system, even in the absence of clinically active tuberculosis elsewhere in the body, and of any definite cytological or chemical abnormality in the cerebro-spinal fluid. And the recognition of such an incident in a patient's history as a danger signal may be a step in the direction of prevention of the deadliest of all forms of tuberculosis.

We wish to express our thanks to Prof. Charles McNeil, Dr. Lewis Thatcher, and Dr. Douglas Nicholson for permission to publish the cases, and for the use of clinical records of patients under their care; also to Lieut.-Colonel W. F. Harvey and Dr. W. O. Kermack, of the laboratory of the Royal College of Physicians of Edinburgh, for cytological and chemical examinations of cerebro-spinal fluids. In the case of one of us (H. J. R. K.) the work reported in this paper was carried out during the tenure of the Kirk Duncanson fellowship for medical research.

CYCLOPROPANE ANÆSTHESIA IN OBSTETRICS

BY WESLEY BOURNE, M.D., M.Sc., F.R.C.P. Canada

(From the Royal Victoria Montreal Maternity Hospital, Canada)

BY the work of Henderson and Lucas [1] done on lower animals at the University of Toronto, by their discovery that cyclopropane possesses anæsthetic properties, by their studies of its percentages anæsthetic concentrations, by their findings concerning its effects on the circulation and respiration, and by their investigation of its influence on metabolism, they were justified in suggesting that it may be developed as a safe anæsthetic for man.

From this suggestion and from such assurances Waters [2] and his collaborators of the University of Wisconsin have gone on to use cyclopropane as an anæsthetic in surgery. They have found that in much lower concentrations it is equal in efficiency to other gaseous anæsthetics, that an excess of oxygen may be administered with this potent anæsthetic, that surgical anæsthesia can be produced in three to five minutes, that laryngeal reflexes are abolished more quickly than with ether, that it causes relaxation comparable with that of ether, that the blood pressure and pulse and respiratory rates are not altered to any appreciable extent, that recovery takes place in less than five minutes, and that the after-effects are very slight. With so much to go on, it seemed safe to use cyclopropane in obstetrics (just as divinyl oxide (vinesthene) [3] has been satisfactorily employed in this clinic during the past year).

In the series of cases herein reported, cyclopropane* was administered through a simple machine devised especially for the use of vinyl oxide in obstetrics and made by the Foregger Company of New York. The principal feature of this machine is a closed system containing alkali for the removal of carbon dioxide from the expired air so that the same anæsthetic may be breathed over and over again, thus making it very economical to use this rather expensive gas. Intermittent analgesia was produced as indicated for the more severe labour pains, and anæsthesia was maintained for the delivery procedures.

The facts of the first administrations of cyclopropane to parturient women are set out in the accompanying Table. This list shows considerable variety in the conditions of the patients as well as in the procedures of delivery. Satisfactory analgesia was easily produced when very small quantities of cyclopropane were inhaled with oxygen. Although none of the times of analgesia was long, I think it would be quite safe to relieve the pains with cyclopropane much earlier in labour than has been done, for the reasons that the uterine contractions have not been inhibited and that so much oxygen was used. We all know that it is good to administer oxygen intermittently—good for the mother and good for the fœtus, especially should the heart of the latter be weak. The use of oxygen in obstetrics is very important. During anæsthesia any required degree of muscular relaxation could be obtained without evident harm, and recovery was devoid of untoward effect to mother or child.

The bromsulphalein dye test [4] for liver function was carried out in three normal cases and in one of eclampsia. Practically no dye was retained in the blood of the normal women when the test was applied about twenty-four hours after the administration of cyclopropane, and as the liver of the eclamptic woman was damaged to an extent of more than 55 per cent. before delivery the damage was not enhanced by cyclopropane, there being less than 50 per cent. dye retention in her blood twenty-two hours after anæsthesia. Corroboration of the effects of cyclopropane on hepatic function has been obtained from experiments on dogs in the department of pharmacology of McGill University. It was found that cyclopropane administered over relatively long periods of time causes practically no impairment of liver function in normal dogs and no additional damage to those previously poisoned with chloroform.[5] It may be pointed out that this feature is equally favourable for cyclopropane and for vinyl oxide [3] when compared with chloroform.[6] It is apposite to mention that any measure of the action of a drug on the liver may be taken as good evidence of what is going on concurrently in other organs, indeed in the rest of the body.

From this inchoative study I may say that cyclopropane seems to be very suitable for the relief of pain in obstetrics, for the following reasons: (1) An abundance of oxygen is given with the cyclopropane. (2) Circulation and respiration are not depressed. (3) Anæsthesia is produced without appreciable metabolic disturbance. (4) Liver function is not impaired. (5) Anæsthesia is quickly and agreeably induced, satisfactorily maintained at any desired depth with ready flexibility and with minimal danger to the mother and child, and recovered from easily and uneventfully.

---

* The cyclopropane was obtained through the generosity of Prof. H. E. Reilley, of the Department of Physics, McGill University.

Clinical and Laboratory Notes

A CASE OF PARATYPHOID A FEVER IN BRISTOL

By J. D. Allan Gray, M.B., F.R.C.P. Edin., D.P.H.

SENIOR PATHOLOGICAL OFFICER, PREVENTIVE MEDICINE DEPARTMENT, UNIVERSITY OF BRISTOL; AND

A. D. Gardner, M.D. Oxon., F.R.C.S. Eng.

BACTERIOLOGIST UNDER MEDICAL RESEARCH COUNCIL, SCHOOL OF PATHOLOGY, UNIVERSITY OF OXFORD

WITH the possible exception of a few cases in travellers returning from abroad paratyphoid A fever can hardly be said to have existed in England since the war. It may therefore be of interest to record the case of an adolescent who contracted it at home without having travelled or associated with travellers. Moreover there is some instruction to be drawn from the serological data on which the diagnosis was based.

Previous History.—A youth, 16 years of age, lived in an orphanage at Bristol, until two years ago, when he went to live with his brother in London. On Dec. 12th, 1933, he was admitted to the Central Middlesex County Hospital suffering from tinea cruris and follicular tonsillitis which both cleared up under suitable treatment. On Jan. 27th, 1934, in accord with regulations, he was sent to a hospital in the area of his previous location, viz., Southmead, Bristol, and came under the care of Dr. P. Phillips. There were no cases of typhoid or paratyphoid fever in the hospital during the patient's stay there, and as far as is known the patient was never in contact with anyone who had been abroad. He had a long history of constipation and megacolon, but apparently had never previously had enteric fever and had never received T.A.B. vaccine.

Clinical History.—The illness began on Feb. 27th and the patient was later transferred to Ham Green Fever Hospital under Dr. B. A. Peters. The clinical features were typical of enteric fever (typhoid or paratyphoid). The onset was insidious with general malaise, dizziness, drowsiness, anorexia, and constipation. The temperature rose by "steps" to 104° F., the pulse was slow, the spleen was palpable (three finger-breadths below the costal margin), and scanty rose spots were observed on the abdomen. One unusual feature was observed, namely, that the spleen remained palpable until March 28th—ten days after the temperature had fallen to normal (March 18th). By the 26th the patient was fit to be out of bed, and recovery was uneventful.

AGGLUTINATION TESTS

Dates (onset Feb. 27th)	H Suspensions. T	A (R.F. 5)	B	O Suspensions. T (R.F. 9)	A (R.F. 2)	B (Aertrycke) (R.F. 6)
March 10th	O (at 25)	2500	O (at 25)	120	25	150
„ 23rd	O (at 25)	700	O (at 25)	150	25	300
May 4th	O (at 25)	10	O (at 25)	10	O (at 5)	30
„ 22nd	—	O (at 5)	—	O (at 5)	—	—

The figures represent the last dilution at which strong partial agglutination was found.

As the accompanying Table shows, the tests with (Oxford) H-suspensions of *Bact. typhosum* (T) and *Bact. paratyphosum* B (B) showed no flocculation throughout (though traces of granular clumping could be detected in the typhoid suspension up to 1 in 50 in the first test), whereas *Bact. paratyphosum* A (A) showed an initially high titre which gradually fell to nothing during the following eight weeks. The O reactions will be discussed below.

Bacteriological Examination.—Repeated tests of stools and urine failed to reveal any organisms of the typhoid-paratyphoid group. No blood culture was done, an omission which is explained rather than excused by its being habitual in this country. We should like to register a plea for the routine practice of this procedure in all cases of suspected enteric fever.

The fluctuation of the paratyphoid A H-agglutinin during the course of the illness is exactly what one would expect in an acute enteric fever, when the first test is done in the middle of the second week—i.e., somewhere near the peak of the curve—and the second a fortnight later, when a rapid fall would be in progress. Neither previous infection nor inoculation could give rise to this phenomenon; nor is there any evidence that the patient had ever undergone either. According to the accepted canons of serology, the production of paratyphoid A flagellar (H) agglutinins in high concentration and a typically falling graph during convalescence can only be due to infection with *Bact. paratyphosum* A. With regard to the somatic (O) agglutinins, the low level of the paratyphoid A, and the more considerable height of the others are surprising, but we do not know enough about the serology of this infection to judge how abnormal this may be. We know that there is a somatic antigen common to the three organisms, in addition to the specific somatic component of each; and it may be that this—the former—is the more active in paratyphoid A fever.

The figures given in the Table for the O agglutinins on March 10th are probably too low, since the serum had been stored for more than a fortnight before testing, and we know that O agglutinins are less stable than H. The apparently delayed peak of the O curves is therefore probably unreal.

Our thanks are due to the physicians in charge of the case for their kind permission to publish it.

SUPPURATIVE OVARITIS FOLLOWING MUMPS

By J. B. McKinney, M.B. Belf.

H. Hilton Stewart, M.D., M.R.C.P. Lond.

AND

H. Ian McClure, M.B., B.Sc. Belf., F.R.C.S. Edin.

We have found no record of ovaritis as a complication of mumps published since 1929, and no British record since 1925. The only report of ovaritis occurring in a mumps epidemic is that of Troitsky,[1] who found non-suppurative ovaritis in 13 out of 33 girls afflicted. The condition was regarded as, pathologically, a peri-oöphoritis. Recovery was the rule and no permanent change in menstrual function is described.

The literature was reviewed by Harlow Brooks in 1913[2] and in quoting the few cases on record he stated that none had been published between 1903 and 1913. He also called in question the diagnosis in a case reported by Meinhardt.[3] This is the only one of suppurative ovaritis following mumps that we can find in the literature, and Brooks's comment is as follows: "Inasmuch as this is the only instance reported in the literature in which metastatic pus formation took place in the ovary, although several instances in which suppuration has taken place in the male sexual gland are recorded, Meinhardt's case cannot be definitely accepted and the possibility of a concurrent appendicitis or salpingitis is suggested." It is therefore important to place on record the following case of suppurative ovaritis following mumps with operation later and recovery.

Mrs. A., aged 43, became ill on Feb. 7th, 1933, with sore-throat and difficulty in swallowing. Her two sons were at this time lying in the same room suffering from typical mumps. Her throat and tonsils were acutely inflamed. A whitish exudate covering the tonsils in parts was easily removed without causing bleeding. Temp., 99·6° F.; pulse-rate, 104. A swab from the tonsils proved negative to *B. diphtheriæ*. On Feb. 8th her morning temperature had risen to 100·2° and the pulse-rate to 106. Both parotid glands were now enlarged and markedly tender, but the submaxillary glands appeared normal. There was definite improvement in the condition of the tonsils. She now complained of headache and nausea, but did not vomit. In the evening the temperature was 103·6° and the pulse-rate 128. On Feb. 9th the morning temperature was 104·8° and the pulse-rate 142. While there was no change in the condition of the parotid glands, the pharynx and tonsils appeared normal. She now complained of severe pain in the epigastrium, and was vomiting frequently. Her tongue was dry and furred. The abdomen moved freely on respiration, without increasing the severity of the pain but there was definite tenderness in the epigastrium. There was no change in the pulse-rate and temperature at noon, but the pain was now referred to both iliac fossæ. The vomiting was replaced by almost continuous retching. The abdomen still moved freely on respiration, but there was marked tenderness low down in both iliac fossæ. There was no rigidity of the abdominal wall, nor was any mass palpable. Rectal examination was indefinite. The patient's condition was unchanged in the evening, save that the parotid swellings were somewhat diminished. (J. B. McK.)

On Feb. 10th the morning temperature was 104·6° and the pulse-rate 144. The abdominal pain was much worse, and retching almost continuous. She had now diarrhœa (one motion per hour), and the stools contained a fair amount of mucus. The tongue was dry and furred and the odour of the breath fœtid. There was no apparent swelling of the parotid glands, but some tenderness yet remained. The abdominal findings were as before, but on rectal examination there was marked tenderness on both sides of the pelvis. Ovaritis was diagnosed. (H. H. S.)

On Feb. 11th the temperature was 99·6° and the pulse-rate 124. Abdominal findings remained unchanged; the retching had yielded to the administration of atropine. In the evening the temperature was 103·6° and the pulse-rate 136. On vaginal examination there was a fair amount of bleeding from the uterus. There was exquisite tenderness in all fornices and the uterus appeared to be retroverted and of normal size with some diminution in mobility. The last menstrual period had finished on Feb. 3rd.

On Feb. 12th the morning temperature was 99·6° and the pulse-rate 92. A mass was palpable in the left iliac fossa. The evening temperature did not change, while the pulse-rate rose to 100. From Feb. 13th–15th the temperature remained normal and the pulse-rate ranged from 76 to 86. While the patient had no symptoms, the mass in the left iliac fossa remained unchanged. Feb. 16th: morning, temp. 99°, pulse-rate 78; evening, temp. 99·8°, pulse-rate 80. Feb. 17th: morning, temp. 99·6°, pulse-rate 80; evening, temp. 104·4°, pulse-rate 96. The temperature then fell to normal and remained so till Feb. 24th, when it suddenly rose to 101·8°. There had been no change in her condition in the intervening period. Coincident with this rise of temperature on the 24th the patient complained of severe pain in the left iliac fossa and began to vomit. The mass was now remarkably tender and nothing could be made out on vaginal examination except that it appeared to be distinct from the uterus, and very tender. It reached almost half-way to the umbilicus.

Under chloroform and ether anæsthesia the abdomen was opened by a midline subumbilical incision by H. I. McC. Pus welled into the wound. The pelvic cavity was closed off by adhesions and omentum. The appendix was lying behind the terminal ileum and was normal. On further examination of the pelvis a considerable quantity of odourless pus was cleared away. Both Fallopian tubes were of normal size and appearance, save for a few adhesions to the bowel. The left ovary was almost entirely necrotic and for the most part had disappeared. What remained was intensely engorged, soft, and on pressure collapsed between the fingers exuding pus. The right ovary was also the seat of a necrotic process but not to such a marked degree as the left. It was a little enlarged and on section was the seat of multiple abscesses, varying in size from a pinhead to that of a pea. The general abscess cavity was cleared out, and the necrotic ovarian tissue removed; it was possible to conserve about one-sixth of the right ovary. The pelvic cavity was drained through the abdominal wound. The retroverted position of the uterus was considered to be a barrier to drainage of the pouch of Douglas through the posterior fornix. Convalescence from the next day onwards was uneventful, and the patient left hospital three weeks later with the abdominal wound completely healed. Nothing was felt on vaginal examination except some thickening in both lateral fornices and complete immobility of the uterus. (H. I. McC.)

This patient has remained well since her illness, and menstruation has retained its normal characters.

Belfast.

MEDICAL SOCIETIES

ASSOCIATION OF CLINICAL PATHOLOGISTS

The summer meeting of this association was held at the Royal Infirmary, Gloucester, on June 23rd. Dr. E. N. DAVEY, pathologist to the hospital, occupied the chair. The proceedings were largely devoted to a consideration of the

Clinical Pathology of Coma

Dr. G. ROCHE LYNCH (London) spoke of the

TOXICOLOGY OF THE BARBITURATE GROUP OF DRUGS

He pointed out that all drugs of this group have the common basis of a combination of malonic acid with urea, the different proprietary preparations being produced by the substitution of various radicles at varying points; some of these preparations in addition to the malonyl-ureide compound also contained various proportions of amidopyrin or pyramidon. A single pharmacological dose produced sleep; repeated doses might in sensitive persons give rise to such symptoms as drowsiness, ataxic gait, ptosis, diplopia, and visual hallucinations. The barbiturates were not cumulative in the ordinary sense of the word, but after prolonged exhibition the effects might be slow in disappearing; the margin between the effective and the toxic dose was small; after a toxic dose symptoms might appear in a few minutes; these were headache, ataxia, vertigo, and drowsiness passing on in to coma; there might be a preliminary period of excitement. On the establishment of coma the plantar reflex might become Babinski in type and the breathing periodic, the pupils were small but not pin point, and the temperature became subnormal; broncho-pneumonia tended to appear after the first 24 hours of coma. The speaker pointed out that many persons showed an idiosyncrasy to the barbiturates and uttered a warning for their use with caution in toxic conditions of the liver, hyperthyroidism, chronic sepsis, renal disorders, and in all states of allergy.

There was considerable variation between the minimum and the average fatal dose. Post-mortem findings were not characteristic; broncho-pneumonia was almost constant but this was of no special type; the liver and kidneys showed fatty and parenchymatous change, but this might be only evident on microscopic examination. It had been pointed out to the speaker by Dr. W. D. Newcomb that the cerebellum frequently showed a pressure cone. Pemphigoid and bullous rashes might appear on the skin.

He questioned whether in all cases returned as suicide from barbiturate poisoning the drug had actually been taken with fatal intent. He recorded one instance in which ten tablets of a barbiturate preparation were taken during one night; on recovering consciousness the patient recollected having taken two only; the remaining eight had apparently been taken in a state of somnambulism induced by the drug. He recommended that in cases where patients are given more than sufficient tablets for one night they be instructed to take the night's dose and then to place the remainder in an inaccessible spot.

In the treatment of barbiturate poisoning Dr. Roche Lynch advocated washing out the stomach; for this purpose alkali should on no account be used as this rendered the poison more soluble; strong coffee and glucose should be left in the stomach and the washout repeated two or three times at intervals of four hours or so. Colonic lavage was useful and should be repeated after 12 hours. Cardiac stimulants should be exhibited in full doses. Lumbar or cisternal puncture was of the utmost importance and should be repeated every 12 to 15 hours so long as the case seemed to demand it. This procedure served both to remove the poison which was excreted in high percentage into the cerebro-spinal fluid and also to relieve cerebral pressure. Other methods of treatment were by strychnine, picrotoxine, and alcohol. Great claims had been made for treatment with strychnine and massive doses had been given. Dr. Roche Lynch, although regarding strychnine as valuable, urged reasonable caution in its use.

In identifying a case of barbiturate poisoning the urine, stomach contents, and cerebro-spinal fluid should be examined for the poison; examination of the cerebro-spinal fluid was of particular importance as drainage should be persisted with until the drug had practically disappeared. The speaker described the methods of identification of the drug in the various body fluids and pointed out that the barbiturates fell into two groups, one of which was rapidly broken down while the other was more stable. Dial belonged to the former group and the amount of this excreted in the urine might be very small.

Dr. J. G. GREENFIELD (London) reported finding excess of protein in the cerebro-spinal fluid; in view of the evidence that cerebral œdema with increase of cerebral pressure played some part in the production of symptoms he queried the safety of cisternal puncture.

Dr. GREENFIELD reported several cases of

SUBDURAL HÆMATOMA

He stated that this condition appears to be becoming more frequent, probably on account of the increase in motor accidents. Its occurrence was much commoner in males than in females. He pointed out that the cerebro-spinal fluid might be absolutely normal and not even under pressure; sometimes it showed slight discoloration of the supernatant fluid after centrifugalisation and an increase of protein, but these features were not constant. Flakes of fibrin might be present in the fluid as withdrawn; their presence constituted an important diagnostic aid. Dr. Greenfield thought it was difficult to account for the long latent period between injury and the onset of pressure symptoms on the assumption of actual continuance of the hæmorrhage. The increased cerebral pressure might be brought about by imbibition of fluid into the hæmatoma, this being occasioned by increase in the osmotic tension of the hæmatoma contents due to breakdown of the blood.

Dr. A. G. SHERA (Eastbourne) described several cases of

COMA DUE TO SUBARACHNOID HÆMORRHAGE

He drew attention to the existence of a spinal as well as a cerebral form; the former never produced coma and was only mentioned for the sake of completeness; in the spinal form the main symptom was severe pain in the back relieved by lumbar puncture. In both the spinal and the cerebral forms the cerebro-spinal fluid was almost invariably blood-stained, the blood was intimately and uniformly mixed with the fluid, and on centrifugalisation the supernatant fluid was coloured to a degree depending on the distance of the date of the hæmorrhage. Besides giving relief to the headache, lumbar puncture was an important diagnostic measure; the condition was usually accompanied by some degree of fever and, short of examination of the cerebro-spinal fluid, the diagnosis between it and meningitis might be impossible. Massive albuminuria might occur and papillœdema and retinal hæmorrhages were common.

Dr. GREENFIELD showed microphotographs demonstrating deficiency of the media of the cerebral vessels to be common at points of bifurcation; it was at these deficient sites that the aneurysms whose rupture gave rise to subarachnoid bleeding were formed.

Dr. F. B. SMITH (Preston) spoke of

DIABETIC COMA

He stressed the importance of the examination of the urine for sugar and acetone in this condition, but attached little importance to the estimation of the blood-sugar. He pointed out that in certain cases uræmia and diabetic coma might occur together; it was important therefore to know the blood-urea level. In treatment he considered that the administration of glucose as a means of combating ketosis should play a prime part; the level of the blood-sugar induced by this glucose feeding he considered to be more or less immaterial and frequent examinations of the blood-sugar were not necessary in the treatment of diabetic coma.

Dr. S. C. DYKE (Wolverhampton) stated that some degree of urea retention was common in diabetic coma and might reach a high degree; he cited one case in which it had reached 350 mg. per cent.; the patient recovered. He considered that it was important in the treatment of diabetic coma to bring the blood-sugar level down to reasonable limits, otherwise the tendency to tissue water depletion was not combated. He advocated the administration of saline rectally, intraperitoneally, and subcutaneously in preference to intravenously.

Dr. L. JANES (Brighton) pointed out that the unlimited introduction of saline into the system might serve to upset the mineral balance of the organism; he suggested that Ringer's solution was a preferable form in which to administer fluid.

Dr. A. RENSHAW (Manchester) asked why, since there was plenty of available sugar in the blood in diabetic coma, it was necessary to give sugar by the mouth.

HYPERTENSIVE ENCEPHALOPATHY

Dr. S. C. DYKE reported seven cases illustrating the occurrence of coma, and in some cases convulsions and other grave cerebral manifestations in association with raised blood pressure. He used the term "hypertensive encephalopathy," first employed by Oppenheimer and Fishberg, to describe the condition. Five of the patients referred to were children or young adults; in addition to coma all these showed convulsions and some of them amaurosis; two patients were elderly, convulsions were absent in these cases. All the younger patients were suffering from acute glomerulonephritis; evidence of renal damage was absent in the elderly subjects. The common feature to all was a raised blood pressure. The speaker pointed out that when occurring along with evidence of renal damage this condition is usually described as "uræmia"; in none of the cases observed, however, was the blood-urea significantly raised, and the term was not therefore applicable. Treatment was by venesection, lumbar puncture, and magnesium sulphate rectally and by mouth, and all cases made a good recovery.

Dr. CUTHBERT DUKES (London) considered that all the cases described were of nephritis and that the manifestations might properly be called "uræmia."

Dr. A. F. S. SLADDEN (Swansea) considered that in the light of present knowledge some examination into the meaning of the term "uræmia" was advisable.

Dr. P. C. HOU (Cheeloo) described a case of

Monocytic Leukæmia

The patient in the course of a short illness during which non-hæmolytic streptococci were isolated from the blood stream showed a white cell count of over 200,000 per c.mm., the increase in the cell count being due to mononuclear cells. By supravital staining these cells gave the appearance of being monocytes. After death nearly all organs showed infiltration with cells of this type. On warm stage preparations of the blood the cells were non-motile.

Dr. E. N. DAVEY (Gloucester) demonstrated specimens from a case of Addison's Disease unsuccessfully treated with Eucortone. At post-mortem examination extensive tuberculous disease of both adrenals was found. An exacerbation of an old tuberculous lesion of the lung waked into activity in the course of the treatment.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

THIS society met at Newcastle-on-Tyne on June 8th, when Mr. FRANK STABLER read a communication on

Blood Reinfusion in Hæmoperitoneum associated with Ruptured Ectopic Gestation

He had performed auto-transfusion in 14 cases of hæmoperitoneum during the last three years; in 13 cases the bleeding was due to acute rupture of a tubal pregnancy, and in 1 it was from a ruptured vein on the surface of a pedunculated subperitoneal fibroid. His technique was as follows:—

> Immediately after arresting hæmorrhage he baled the fluid blood out of the abdomen with a coffee cup into a pint glass measure, containing one ounce of 2 per cent. sodium citrate solution, and covered with six to eight thicknesses of muslin gauze soaked in citrate. The whole was kept in a basin of water at 100° F., and one ounce of citrate solution was added as the blood was baled in. If there was any difficulty in securing enough blood, the table was lowered from the Trendelenburg position. The reinfusion was done immediately after the abdomen was

closed. He used the most suitable vein at the bend of the elbow, making a diagonal incision, and tying in a cannula, and ran in the blood at a rate not faster than one pint in one hour.

Mr. Stabler quoted several typical cases: one had a blood pressure of 54/38 on admission, ten hours after rupture, the temperature being 96° F. and the pulse 132, impalpable at the wrist. When the abdomen was closed the blood pressure was 65/40. During transfusion it went up gradually and at the end of transfusion it was 115/63 with a pulse-rate of 132. It was common for blood pressure to rise 20 to 30 mm., red cell count to rise by 1½ to 2 millions, and hæmoglobin to rise 20 points. Control cases showed that blood pressure did not rise as a result of anæsthesia, the Trendelenburg position, or hæmostasis alone; in fact, where transfusion was not done there was a fall in blood pressure for two hours of about 10 points, so that transfusion actually produced a gain of 30 to 40 mm. blood pressure. Regarding the possibility of introducing infection with the blood, Mr. Stabler thought that the blood stream was the safest place to put organisms other than hæmolytic streptococci, and if those organisms were present in the abdominal blood the end-result would probably be the same whether they were injected into the blood stream or not. However, blood in the peritoneal cavity often became infected after about 48 hours, and therefore reinfusion was always avoided if the acute rupture had occurred more than 24 hours before operation or if there was fever. Multiple pulmonary embolism from rouleaux of corpuscles or small clots were possible; in this connexion Mr. Stabler regarded the rate of injection as important. One patient died 42 hours after operation, but death was not attributable to the reinfusion. Since the pathologist's report on the autopsy was: "Button-hole mitral stenosis; lungs show chronic venous congestion and three small patches of bronchopneumonic consolidation; microscopically they do not show any evidence of embolic blocking."

Mr. HARVEY EVERS read a communication on the

Lower Segment Cæsarean Section

detailing his experience in 150 cases. The results were as follows:—

—	Mothers died.	Babies.		Morbidity.
		Stillborn.	Died.	
Whole series (150)	4	5	6	29
Cases operated on before labour (27)..	0	1	0	2
Suspect or septic cases (123) ..	4	4	6	27
Failed forceps cases (24)..	3	2	3	14
Suspect cases, excluding failed forceps (99)	1	—	—	13

The results were very satisfactory as a whole. The figures for suspect cases were extremely good considering that many of the cases would have been regarded by some obstetricians as unfit for Cæsarean section. The failed forceps group, as might be expected, gave the worst results, but in view of the serious condition of several of the patients he thought them reasonably good. 75 per cent. of the maternal and nearly 50 per cent. of the fœtal mortality occurred in this group, and the morbidity was high. It would be difficult to produce a parallel series of cases treated by the classical method with such satisfactory results.

The following were the four fatal cases:—

CASE 23.—Failed forceps; died of general peritonitis on the fifth day. It would have been better to drain this case.

CASE 58.—Emergency. Prolonged labour; membranes ruptured 12¼ hours; died of broncho-pneumonia on the 31st day.

CASE 73.—Failed forceps; retained placenta, removed manually after operation; died of broncho-pneumonia on the 36th day.

CASE 84.—Failed forceps; much damage to soft parts; died of broncho-pneumonia on the 7th day.

Indications.—The great majority were cases of contracted pelvis. In some the operation was done after trial labour, and the basic factor at fault was poor uterine action rather than disproportion. It was in these cases that the lower segment approach had special advantages over the classical method; it reduced the number of inductions of labour. In 5 cases there was a placenta prævia, but in only 3 of them was it the real indication for operation; there was troublesome hæmorrhage, and Mr. Evers was not impressed with this means of access for this type of case. Fibroids were present in 4 cases, but only provided the indication for interference in 1; the fibroid was posterior, and though it obstructed labour it did not interfere with the approach to the lower segment. There were several cases of breech presentation, several elderly primiparæ, and 1 of sacro-coccygeal tumour. In 3 cases the operation followed induction of labour which had failed; 1 of them showed severe morbidity. In 1 case the cord was 100 in. long and was round the neck nine times.

Technique.—Mr. Evers agreed with Mr. Stabler that a douche followed by antiseptic treatment of the vagina and cervix was sound practice, though he had only had this carried out on rare occasions.

Anæsthesia had usually been general, never local; spinal anæsthesia was used twice. The patient was horizontal, a slight Trendelenburg position was used in the early cases, but it was not essential and encouraged flow of septic matter from the vagina into the uterus. The incision used was the ordinary low vertical subumbilical transperitoneal incision; on two occasions when the extraperitoneal route was used it was unsatisfactory. It was important that the bladder should be quite empty. The peritoneal cavity was packed off by gauze. The peritoneum of the utero-vesical pouch was incised transversely and the bladder pushed down. This was only liable to be difficult in repeat cases. In 16 of the early cases a transverse uterine incision was used; it had, however, no advantage in delivering the head, bleeding was more severe, and it was difficult to prevent tearing into the blood-vessels at the sides. A vertical incision was now used; the uterus should be pushed into the middle line first, and any torsion present undone; an accurately median vertical incision minimised hæmorrhage. It should begin as low as possible, and should be extended upwards by scissors. Extension downwards of the incision during delivery might wound the bladder, and extension or tearing up into the upper segment increased bleeding and weakened the scar. The membranes were preserved while the incision was made; then 1 c.cm. of pituitary extract was injected into the uterine muscle. Bleeding from the cut edges was controlled by catch forceps or by special forceps designed by Mr. Evers.

The head was delivered by lifting the caput and moulded part of the head up into the wound; then pressure was exerted on the fundus, the head being kept fully flexed. The previous injection of pituitary was a great help. In difficulty, one or both blades of a pair of short forceps were used. This was often necessary in cases not in labour, or when the head was floating. One blade was used in 20 cases, two blades in 10 cases, and the feet were extracted first in 8 cases of deliberate version or of breech presentation.

Delivery of placenta and membranes.—In 15 of his early cases Mr. Evers delivered the placenta per vias naturales at the end of the operation. Case 73, in which the retained placenta had to be manually removed, induced him to discard the method. This was a failed forceps case, and the manual removal might have contributed to the fatal result. Since then he had always waited for the placenta to separate, and in many cases it was expelled into the lower segment and could be removed by roping the membranes. In a few the hand must be passed into the upper segment to remove it, but this should be avoided if possible. The uterus was closed by two layers of sutures and the peritoneum by continuous catgut. There was complete lack of tension, apposition was excellent, and healing sound. In suspect and failed forceps cases, a piece of tissue drain was split at one end; one portion drained the uterine wound, and the other the utero-vesical pouch. It should not be removed too soon.

Repeat cases.—There were 39, of which 29 had had classical and 10 lower segment operations; of the 29, 3 had had two previous operations and 1 had had three; of the 10, all had had only one previous operation. In one lower segment case the upper segment had been encroached on and the scar was thin at that point; in the others there was no sign of scar. In patients becoming pregnant again (49 cases after the lower segment operation, there has been no case of ruptured scar. Some had had normal delivery at full term, many have had induction, and many have had repeat operations.

Mr. Evers summarised the advantages of the operation as follows: (1) Trial labour can be made with much less risk. This diminishes the number of Cæsarean sections and inductions. (2) The danger of sepsis is much less and if it occurs it is likely to be pelvic and not general. (3) There is a definitely lower maternal mortality in suspect and failed forceps cases. (4) The operation, though technically more difficult, is accompanied by much less hæmorrhage. (5) The convalescence of the patient is considerably less stormy. (6) The risk of subsequent rupture of the scar appears very slight. The only disadvantage of the operation is that it is admittedly sometimes difficult to do in cases not in labour.

Dr. FARQUHAR MURRAY read a communication on

The Value of Lipiodol and X Rays

in the diagnosis and treatment of pelvic mischief. The technique adopted consists of injecting 8 c.cm. of slightly warmed lipiodol by means of the screw syringe provided by Messrs. Bengué. The patient was under anæsthesia and the vagina and cervix had been swabbed with acriflavine. The cervix was not dilated but was clamped to the cannula by a volsellum. The patient was sent to the X ray department with the volsellum still clamping the cervix, and a second photograph, which was essential for correct interpretation, was taken in 24 hours. In a normal case the shadow of the uterine cavity, attenuated threads representing the tubes, and a mass, usually well defined, near the ostia, were visible. In 24 hours the uterine and tubal shadows had disappeared and there was merely diffuse blurring. The presence of vaginal shadow and clinical observation indicated that drainage in these cases was both per abdomen and per vaginam. Normal tubes were distensible and also contractile, and this was a disadvantage when neo-hydriol, a preparation thinner than lipiodol was used, as far as the shadows were concerned. Dr. Farquhar Murray discussed the interpretation of tubal and terminal shadows, which were of great importance. With regard to sterility lipiodol provided a method of obtaining information which prevented purely speculative and often futile operations.

> There were three main types of case. In the first the uterus was shown up in the photograph, but not the tubes. Operation was not advised here, as the state of the tubes was unknown and a plastic operation at the cornua produced results too speculative to be justified. In the second type, the solution distended the tubes to the abdominal ostium, which was sealed. Terminal blobs of solution were observed in 24 hours. This showed patency and normality of the tube as far as the ostium and salpingostomy was indicated. In the third type the solution passed to the abdominal ostium merely as a fine thread; in 24 hours there were only two small dots corresponding to the ends of the tubes. This, in Dr. Murray's opinion, probably means fibrosis of the tube; the result of salpingostomy in such a case was very doubtful.

Sometimes lipiodol with an X ray revealed an error in the insufflation test.

In cases of pelvic pain where examination was negative and diagnosis rests between urinary and tubal infection, Dr. Murray, with the idea of avoiding operation if possible, proceeds as follows:—

> The general condition and urinary tract were treated for two months, citrates, bromides, and aperients figuring prominently in the régime. If this did not cure, injection of lipiodol and X ray examination was done. Laparotomy was advised if the solution did not enter the tubes. If it entered the tubes but did not escape into the abdomen, or if it passed into the abdomen freely with normal photographs, further symptomatic treatment was recommended.

If the shadows appeared normal, one would be reasonably certain that the tubes were at fault if the patient admitted that the injection made the pain worse, and by the indirect evidence that in some cases the pain had been ultimately relieved. If a definite lesion is proved to exist operation was not done, because the damage could not be gross or it would have been palpable. If the solution reached the ends of the tubes, though it failed to reach the abdomen, the existence of tubal drainage was proved and this justified optimism. If the pain remained after a further two months' treatment, operation was justified.

In cases of chronic cervicitis and vaginitis which required radical disinfection, it had been his rule to inject lipiodol and have the cases X rayed. Definite proof of tubal disease was sometimes found even if there was no pain. Lipiodol and X ray examination gave useful information in cases [illegible] in young women not only abou[illegible] dage, but also about the one which it was hoped to conserve. This may mean intelligent instead of speculative treatment at laparotomy.

Cases were described by Dr. FARQUHAR MURRAY and Mr. HARVEY EVERS.

WOOLWICH WAR MEMORIAL HOSPITAL.—This hospital, opened six years ago with 112 beds, is already so seriously inadequate that an appeal is being made for £50,000 for enlargements. There is a waiting-list of 202, and the bed accommodation is exceeded. In consequence of extensive building the population is definitely growing and the position is officially described as a "terrible problem." The allocation of the wards is unsatisfactory, and since there is only one ward for men it has become the invariable practice to admit urgent cases to the children's ward. There is a maternity ward for eight mothers, but on one occasion in the past year 15 mothers and 14 babies were being nursed. The housing of the nursing staff "causes considerable concern" and the radiological departments are proving too small for requirements. The weekly cost per patient last year was £3 9*s.* 6*d.*

REVIEWS AND NOTICES OF BOOKS

1. Nephritis and Allied Diseases

Their Pathogeny and Treatment. By ROBERT PLATT, M.D. Sheff., M.R.C.P. Lond., Physician, Royal Infirmary, Sheffield; Visiting Physician, Montagu Hospital, Mexborough. London: Humphrey Milford, Oxford University Press. 1934. Pp. 166. 7*s.* 6*d.*

2. Hypertension and Nephritis

Third edition. By A. M. FISHBERG, M.D., Associate Physician to Beth Israel Hospital; Associate in Medicine, Mount Sinai Hospital, New York City. London: Baillière, Tindall and Cox. 1934. Pp. 668. 32*s.* 6*d.*

1. Dr. Platt has succeeded in less than 200 pages in presenting a clear and readable account of the main features of nephritis. Beginning with a chapter describing the anatomy and physiology of the kidney, in which his views are largely based on those of Cushny and Verney, he proceeds to describe the main changes in renal function occurring in disease. His discussion of the relative importance of such factors as the diminution of the serum protein and salt-retention in the production of œdema is lucid and well reasoned, and the third chapter which deals with tests of renal function is particularly valuable in that the tests given are fully up to date and prolixity is avoided. In later chapters Dr. Platt illustrates various types of disease by examples from his own experience. It is perhaps unfortunate that he should not have separated the various types of disease which are usually included in the term "eclampsia," and it is perhaps possible at the present day to discuss the treatment of that condition with rather greater assurance than the author feels to be justified. Essential hypertension is disposed of in a chapter of nine pages and brevity has perhaps been carried too far, for the less instructed reader may fail to recognise the importance of many features of the disease described. The occurrence of papillœdema is, for example, not mentioned, and throughout the book the description of various ocular manifestations in nephritic and hypertensive states might be amended. In spite of these small defects, few, if any, better books on this subject are available at the present time.

2. For the earnest student, eager to get clear knowledge concerning diseases of the kidneys, the appearance of the third edition of Dr. Fishberg's book provides a great opportunity. To the physician versed in this branch of medicine it is an event. Considerable additions and alterations have been made. The subjects of extrarenal nitrogen retention, hypochloræmia, and albuminuria due to cerebral lesions are amongst the more important additions, whilst those interested in therapeutics will find the use of salyrgan, magnesium sulphate, and acacia fully discussed.

The last edition of Dr. Fishberg's book appeared in 1931. The present volume is larger by over 50 pages, and it may perhaps be asked whether the author will not next produce a magnum opus in several volumes together with a short handbook more suitable to the purse and desires of the student. Whether he does so or not the existing form of his book is unquestionably a very fine presentation of the subject. Every chapter is admirably documented with references, neither the ancient nor the latest investigators escape the eye of the writer; at the same time Dr. Fishberg never loses sight of the fact that nephritis and hypertension are diseases which must remain in the care of the general practitioner, that laboratory facilities on an extensive scale are not always available, and that the practical outlook is essential.

The book is one which should be read and re-read by student, physician, and pathologist.

Moderne Therapie der Neurosyphilis

By BERNHARD DATTNER, Dr. Med. et Jur., Vienna. Vienna: Wilhelm Maudrich. Pp. 334. RM.22.

THAT a monograph of over 300 pages should be required for a full examination and discussion of present-day methods of treating neurosyphilis is surely a striking commentary on their unsatisfactory nature. Were treatment as specific as the treponeme appears to be there would be one method, and one alone, just as typhoid fever and diphtheria can be successfully and specifically combated. But the existence of therapeutic variety and diversity can only mean that no one procedure is reliably curative. Dr. Dattner's review covers the whole field of general paralysis in convenient fashion; he makes six classes of technique—viz., treatment by (1) infective disease, (2) avirulent material, (3) unspecific chemical substances, (4) new specific medicaments, (5) physico-chemical methods, and (6) sunray and personal blood injections. Each is discussed critically, weighed in the balance, annotated, and summarised. For tabes a similar line is followed, but there is more to be said of symptomatic treatment here, as perhaps is natural. The treatment of cerebro-spinal syphilis is also described.

On the whole, we consider that the usefulness of tryparsamide is under-estimated by the author, and the value of malaria and recurrent fever technique rather overstressed. None the less no one can fail to note how much the burden of treatment has been lightened by methods in vogue to-day, and how general is a feeling of hopefulness. The book is enriched by numerous tables and illustrations, and provides also a summary of lumbar puncture procedures and tests.

External Diseases of the Eye

By DONALD T. ATKINSON, M.D., Consulting Surgeon to the Santa Rosa Infirmary and the Nix Hospital, San Antonio, Texas. London: Henry Kimpton. 1934. Pp. 704. With 479 engravings. 35*s.*

THE details of external diseases in this book are profuse. About 150 pages are devoted to diseases of the eyelids alone; these include congenital anomalies, affection of the skin, fungus diseases, tumours and operations on the lids. For ptosis, five different operations are described, but there is no reference to operations which utilise the superior rectus muscle or to Hess's operation. Clinically we miss any warning of the danger to the cornea if inefficiently protected after any operation for ptosis. No less than 12 operations for ectropion are described and 10 for entropion, but not the simple operation of excising skin and muscle for spasmodic entropion of the lower lid. For lacrymal disease Meller's (misprinted "Müller") procedure for excision of the sac is described—not so fully as it deserves, and though

Toti's and West's operations are not referred to, the author advocates the temporary insertion of a rubber drainage-tube through an opening into the nose. The chapters on conjunctival and corneal diseases are on a similar scale, but so much space is devoted to rare conditions that the commoner ones are apt to get crowded out. Angular conjunctivitis, for instance, is only referred to in passing, and the specific effect of zinc sulphate on the Morax-Axenfeld bacillus is not mentioned. The bacteriology of the conjunctiva, which is of great practical importance, finds no place in this book.

Besides external diseases, properly so-called, there are chapters on the iris, ciliary body, lens, and on glaucoma. These subjects are not dealt with in the same detail as the rest, and there is no reference to fundus conditions, even in glaucoma. The usual operations are described and illustrated. The subject of refraction is outside the scope of the work. In the chapter on the eye muscles several operations are described, but no adequate treatment of concomitant squint is described and no reference to its orthoptic treatment.

On the whole the work is valuable, chiefly as containing accounts of a number of rare conditions such as yaws and leprosy and rare fungus diseases, which will with difficulty be found elsewhere. The numerous drawings in black and white are clear and useful, and so are the many photographs, taken not directly from a patient but from wax models. Four interesting drawings illustrate the results of optical iridectomies or iridotomies, in which the author succeeded in restoring useful vision to patients previously given up as blind.

Operative Gynecology

By Dr. H. V. PEHAM, Privy Councillor, Professor of Obstetrics and Gynecology; Chief of the I. Frauenklinik of the University Vienna; and Dr. J. AMREICH, Privatdozent for Obstetrics and Gynecology of the University, Vienna. With an introduction to the edition in English by GEORGE GELLHORN, M.D., Professor of Clinical Obstetrics and Gynecology, Washington University School of Medicine, St. Louis, Mo. Authorised translation made by L. KRAEER FERGUSON, M.D., Associate in Surgery, University of Pennsylvania. London: J. B. Lippincott Company. 1934. Two volumes. Pp. 779. 5 guineas.

WE agree with Prof. Gellhorn, who in his introduction, says that the authors deserve much credit for having made this monumental work accessible to the English-speaking public. The first volume deals with such matters as the design and management of the operating theatre, the nature of anæsthesia advised, and post-operative complications. The last eighty pages contain a detailed description of the relations in the pelvis, the blood-vessels, nerves, and lymphatics, and the ureters. In the second volume are descriptions of the actual operative procedures recommended. The authors have chosen to describe in detail one, or at most two, operations for the surgical cure of any condition. The treatment of cervical cancer receives keen attention, and the chapter devoted to it includes a quantity of carefully collected statistical data on the end-results that may be expected. For the cure of prolapse the orthodox repair of the pelvic floor is advised; vaginal hysterectomy is not considered in this connexion. For prolapse associated with urinary incontinence it is claimed that the best results are obtained by the interposition operation. Baldy's operation is recommended for the operative correction of a retroverted uterus, and vaginal operation for the repair of bladder fistulæ.

The production of the work deserves high praise. Almost all the illustrations, and they are extremely numerous, are original, and the artist, Karl Hajek, has faithfully reproduced the pictures familiar to those who have wide clinical and surgical experience, and the operative details are shown so clearly that the procedure is easy to follow. Paper, type, and arrangement are alike excellent. This work will appeal to all interested in gynæcological surgery, but it will be most appreciated by the young specialist. As Prof. Gellhorn remarks, so complete are the descriptions, so exhaustive is the recital of technical minutiæ, and so impressive are the pictures that the reader may well imagine himself present at the operation.

Diseases of the Spinal Cord

By WILLIAMS B. CADWALADER, M.D., Professor of Clinical Neurology, University of Pennsylvania Medical School. London: Baillière, Tindall and Cox. Pp. 204. 29s.

Dr. Cadwalader's unambitious and handy book on diseases of the spinal cord is intended for the student of medicine, neurologist, surgeon, and general practitioner; as such, it ought not to vie with more elaborate text-books on the one hand, or with mere vade-mecums on the other. A serious endeavour has been made to set down in concise and accurate fashion the cream of present-day lore in regard to the subject, so that no reader will be disappointed. This is a difficult matter, as Dr. Cadwalader is well aware; but he has discharged his task with considerable success. He gives us evidence of original investigation as well as of wide knowledge of the literature; his descriptions are compact and tidy, as befits his aim; the illustrations, clinical and pathological, are well chosen. There is little in the volume with which any will disagree; perhaps the author rather over-states his case in claiming that primary lateral sclerosis is "now accepted as a distinct entity"; and it is premature, surely, to hold that muscular dystrophy, Thomsen's disease, and certain other conditions here examined are dependent on disturbances of the sympathetic system.

Whither Medicine?

By JOSEF LOEBEL. Translated by L. M. SIEVEKING and I. MORROW. London: Sidgwick and Jackson. 1934. Pp. 296. 7s. 6d.

THE curious title of this book was no doubt chosen in the belief that a knowledge of the past is of interest only as a guide to the future, for in simple language it is a semi-popular history of medicine and the medical sciences. It deals less with facts—though plenty of these are stated—than with general trends of outlook and atmosphere, and it will be found interesting reading by those who have a liking for a mildly philosophical outlook. It preaches sound general doctrine, such as for example that the body works as a whole, and the details seem to be, in the main, as accurate as one can expect from an author who attempts to cover such a large field. The translation is efficient, though one rather doubts whether such expressions as the "precipitation" of sugar on page 90, and the "pus" of a cerebral tumour on page 181 really represent the sense of the original.

THE LANCET

LONDON: SATURDAY, JULY 7, 1934

BACTERIOPHAGE IN CHOLERA

D'HERELLE's early thesis "that the bacteriophage might be used as a benign parasite to wage war upon pathogenic organisms for the benefit of man and beast"[1] naturally aroused more than academic interest, and reference to our columns over the past four or five years will provide sufficient testimony to the energy with which his idea has been pursued. Such a study will, however, make equally clear that in the now considerable mass of literature on bacteriophage therapy there has so far been lacking any substantial measure of agreement about the results obtained and about their proper interpretation. This absence of precision or finality as the outcome of much experimental work has led us repeatedly to urge that only by test on a large scale, carried out with adequate controls, recorded fully and accurately and evaluated statistically, can there be any hope of determining the preventive and therapeutic value of this agent. In 1931 Lieut.-Colonel J. MORISON, addressing the section of epidemiology of the Royal Society of Medicine,[2] whetted appetite for such a formal trial with a preliminary account of the field experiments being carried out in India. Since then these tests have been continued and extended under his direction with the assistance of Dr. E. MILFORD RICE and Dr. B. K. PAL CHOUDHURY, under grants from the Royal Society and the Indian Research Fund Association. The work now extends, therefore, over a period of several years, and the April issue of the *Indian Journal of Medical Research* contains a detailed statistical examination of the large amount of material collected and the results so far reached. This report, which needs close consideration, is divided into four sections. In the first the discussion turns upon the incidence of cholera in areas in which bacteriophage has or has not been utilised as a means of prevention. The second gives an account of district epidemics in villages and upon tea estates. In the third the fatality-rate of treated cases is examined, and in the fourth statistics bearing upon the influence of bacteriophage therapy upon infectivity are analysed.

To measure the effect of bacteriophage upon incidence, two districts in the province of Assam were selected, Nowgong and Habiganj. Each contains a population of over half a million persons, and possesses a dying river, along which, as MORISON has shown, cholera tends to appear; both are situated in the plains, but they are 140 miles apart in different river basins. In Nowgong the distribution of bacteriophage began in December, 1929, in Habiganj not until June, 1932, so that in the latter at present the experimental period is too short to be of service. As controls to the experience in Nowgong the authors take (1) the previous incidence of cholera in the area and (2) the contemporary incidence of cholera in distant Habiganj, and also in similar areas more closely situated. In Nowgong the deaths per 10,000 of the population have been, for 1930, 0·99, for 1931, 0·78, for 1932, 0·46, and for 1933, 0·36. Examination of the death-rates between 1906 and 1929 shows that the lowest previously recorded in the area were 1·34 in 1918, 1·42 in 1920, and 1·62 in 1923. There has been no previous recorded period in which the death-rates for four consecutive years have been comparable with those of 1930 to 1933. The distribution of bacteriophage has thus been associated in time with an abnormally low mortality from cholera. In space, the comparison lies mainly between Nowgong and the district of Darrang, which adjoins Nowgong on the opposite bank of the Brahmaputra. Between 1906 and 1929 there was a considerable degree of association between the level of their death-rates from cholera in each month of the year; between 1930 and 1932 there was none. The mortality both in the adjacent area of Darrang and in the more distant area of Habiganj showed no decline in 1930 to 1933 on the scale of that experienced in Nowgong. "Something," it is said, "has happened in Nowgong which has not happened before and has not happened in the control areas." Of that there seems to be no doubt; but is that "something" the result of the distribution of bacteriophage? The answer must be that the association both in time and space is *perfectly consistent* with that hypothesis, but on the other hand the present limitation of the observations both in time and space makes it impossible to accept the results as yet as definite proof of cause and effect. We cannot be sure that some one or another unknown variable, that may affect the incidence of cholera, has not also changed in Nowgong concurrently with the administration of bacteriophage. For instance, the figures show that in Darrang, the death rate, taking the average of three year periods, fell steadily from 1924–26 to 1930–32, and in 1930–32 was lower than had ever previously been recorded, though remaining at a level considerably above that of Nowgong. A longer period of observation, an extension of the therapy to other areas, will eventually strengthen what is at present a striking and suggestive result.

Further evidence favouring the efficacy of bacteriophage is, however, available in the other sections of this report which deal with fatality and infectivity. In so fatal a disease as cholera the ideal method of evaluation, the use of bacteriophage on alternate cases in villages, was not possible; "it would certainly result in a riot should one form of treatment seem less efficacious than another." The method of analysis, therefore, in comparing treated with untreated cases has been to examine carefully all other factors that might, it was considered, differentially affect the fatality rate —e.g., age, sex, caste, and period of the epidemic in which the cases occurred. For such study results are available from two epidemics.

---

[1] See THE LANCET, 1932, ii., 198.

[2] Ibid., 1931, ii., 1311.

The first, in Sibsagar, is divided into three consecutive periods of time, and the fatality rates of the treated and untreated are thus compared at, broadly, each stage of the epidemic. In each of these periods the cases treated with bacteriophage within 48 hours of onset were observed to have an appreciably lower fatality rate than the untreated cases—namely, 24·6, 23·5, and 20·0 per cent. as compared with 51·8, 40·4, and 34·9 per cent. in the untreated. From the results it appears that the bacteriophage-treated patients had their greatest advantage in the earlier and more fatal stage of the epidemic. As the virulence declined, as measured by the decreasing fatality rate of the untreated, the fatality of the treated remained approximately constant—a rather curious phenomenon. Such a form of comparison, however, as the authors point out, may unduly favour the treated group of patients, for cholera is in some cases so rapidly fatal that even when treatment is at hand every case has not the same chance of treatment. The untreated will inevitably have more deaths, for they include the severest cases. To allow for this, the authors adopt the process of excluding from the untreated group all deaths that occurred on the first day of illness, while making no alteration in the treated group. Still it was found that the untreated suffered a greater fatality rate than the treated, while from further analysis it appeared that the administration of bacteriophage upon the first day led to the greatest reduction in mortality. In a second and more virulent epidemic than that of Sibsagar—in the Darrang villages—the mortality in the treated group was nearly half that in the untreated: after, on the principle explained above, deducting the fulminating cases from the untreated group and leaving the bacteriophage group untouched, the fatalities were 78·1 per cent. for the untreated and 44·4 per cent. for those receiving bacteriophage within 24 hours.

Here again we have a strong prima facie case in favour of bacteriophage but we hesitate to accept it as more than that. The authors have certainly done all in their power to prove an equality of characteristics between the treated and untreated groups, but in the absence of a deliberately random allocation of cases to each group one cannot escape the question whether some unknown and possibly important factor may not have been responsible for the fact that "Mr. X" is found amongst the untreated and "Mr. Y" amongst the treated.

To say that rigid proof is still lacking is not to underrate either the importance of the work that Colonel Morison and his associates are carrying out or the value of the evidence they now put forward. Extension of their observations in time and space must place their case for the prevention of cholera by means of bacteriophage on a firmer foundation, and we trust that such an extension will be found possible. The case for treatment is more difficult. Further observations on the same lines can hardly do more than confirm the present result without making it any more secure. A random distribution of cases to the treated and untreated group is the only unassailable mode of procedure, but it is a method that demands, in dealing with human beings, two perhaps impossible requirements—namely, a complete lack of faith in the therapeutic agent employed, and a population "at risk" to which the test can be applied without the differences in the treatment given being conspicuous. Perhaps it is only in fiction that such a situation could be created.

TUBERCULOUS MENINGITIS

The accepted teaching of the pathogenesis of tuberculous meningitis is that it is a part of a general miliary tuberculosis, the blood stream carrying all over the body large numbers of bacilli derived from some focus of disease in the thorax, abdomen, or elsewhere, and the meninges of the brain sharing in this general infection and then becoming the seat of inflammation and exudation. This doctrine has been challenged by Rich and McCordock as a result of a careful anatomical study of the brain and spinal cord in 82 cases of tuberculous meningitis,[1] and quite a different explanation of the origin of meningitis was suggested by them. By careful and complete sectioning of the brain and cord they found in all but 5 of their 82 cases one or more caseous foci in close proximity either to the meninges or to the intraventricular surfaces, and actually extruding caseous material into the subarachnoid space or the ventricles. In the 5 cases where the examination was incomplete, older foci were occasionally found, although evidence of their communication with the surface was not obtained. These foci were visible to the eye, but most of them were beneath the surface of the brain and would easily escape detection in any but a very searching examination of the brain. This proof of the existence of older caseous tuberculous foci in the brain in practically every case of tuberculous meningitis led the authors to the conclusion that the disease results from a local infection with caseous material, heavily loaded with tubercle bacilli, rather than from miliary tubercles in the meninges. It is true that in most cases of tuberculous meningitis, especially in young children, there is also a general miliary tuberculosis which includes the surface of the brain; but in a significant number tuberculous meningitis is present without general miliary tuberculosis. Further in support of the view of Rich and McCordock is the common experience of finding miliary tuberculosis of the lungs, the liver, spleen, and kidneys, without any exudative inflammation of the pleura and peritoneum in close proximity; while yet another point in favour of their theory is that it gives a better explanation of variations in onset and course of the meningitis. The discovery of older tuberculous lesions in the brain in nearly all cases of tuberculous meningitis suggests an analogy with the primary Ghon focus in the lungs. The analogy is not complete, but it goes some distance. In the brain, as in the lung, there is a primary deposit. In both organs it is a small focus and has to be searched for with special care or it will be missed. In the lungs it is deposited by the airways; into the brain it is carried by the blood stream. In the lungs it is generally single; in the brain it is often multiple.

Rich and McCordock's theory would serve to explain the occurrence of such rare cases as are reported on another page by Dr. Macgregor,

[1] Bull. Johns Hopkins Hosp., 1933, lii., 5; see also The Lancet, 1933, i., 651, and 1933, ii., 192.

Dr. Kirkpatrick, and Dr. Craig, in which a few tubercle bacilli find their way into the cerebro-spinal circulation from an adjacent focus, but fail to set up meningitis. In these cases infection of the cerebro-spinal fluid by tubercle bacilli was proved by animal inoculation. The children all reacted to the tuberculin test, but they neither showed the clinical features of tuberculous meningitis, nor did they develop this complication after a period of many months. In two of the cases the cerebro-spinal fluid was practically normal in its chemical and cellular constitution, and here the type of bacillus was bovine; in the third, the fluid showed an inflammatory reaction similar to that of tuberculous meningitis and was found to contain bacilli of human type. (Of the 214 cases of tuberculous meningitis analysed by Dr. A. S. Griffith in our last issue about a quarter were due to bovine bacilli.)

The interesting results recorded by MacGregor, Kirkpatrick, and Craig were obtained in the course of a study of tuberculous meningitis in children which is still proceeding, and which attempts to correlate its clinical, morbid, anatomical, and bacteriological aspects. They are significant in several ways. They are not presented as examples of recovery from tuberculous meningitis—a rare event of which a certain number of authentic cases are on record, occurring nearly always in older children and adults. They belong to the still rarer group of tuberculous infection of the cerebro-spinal fluid without meningitis. The occurrence of three cases of this kind in the course of one investigation suggests that this condition may be commoner than has been believed. In such cases a general miliary tuberculosis as the result of a heavy infection seems impossible, although there remains the possibility of the escape of a few bacilli from the choroid plexus. The further history of the cases will be of great interest, since their significance is much greater than that associated with rarity. When studied alongside cases of typical meningeal disease they should add considerably to our knowledge of the pathology of tuberculous meningitis. It is desirable that so fatal and so common a disease should be studied in one comprehensive investigation; the new observations on the morbid anatomy of the disease must be tested and verified; the bacilli must be typed; and a complete neurological record of the cases must be made so that clinical and pathological observations may be correlated. When we remember that tuberculous meningitis is not a primary disease; when we are now told that the meningitis is the result of an older focus of disease which may be here, there, or anywhere on the surface or in the interior of the brain, and that the choroid plexus and the spinal cord must not be forgotten; and when we realise that this older local deposit in the brain has come from a primary focus of disease in the thorax, abdomen, or almost any part of the body, we begin to appreciate the labour entailed by a thorough study of the disease from its beginning to its fatal close. Such a task is, of course, beyond the powers of an individual; the collaboration in the Edinburgh investigation of a morbid anatomist, a bacteriologist, and a clinician gives promise of valuable results from the completed study.

THE CHILD WITH POOR SIGHT

"Blindness," as it affects children, was defined by the Education Act of 1921 as "too blind to be able to read the ordinary school-books used by children," and this definition has been extended in practice to cover all whose sight will probably be made worse by following the regular school curriculum. To call these children blind is not only incorrect but harmful, for it creates a quite unnecessary feeling of dread both in the children and their parents. The first recommendation of the Board of Education Committee,[1] presided over by Dr. Ralph Crowley, is that no child should be certified as blind who is unlikely to be put in the class designated by the Blind Persons Act of 1920 as "so blind as not to be able to perform any work for which eyesight is essential." The committee was invited to consider the problems of the "partially blind," and it begins its report by asking permission to call them "partially sighted." This group comprises first, those who cannot follow the ordinary curriculum but can see well enough to be taught by special methods involving the use of sight, and secondly, those suffering from conditions such as myopia, which may be aggravated by following the ordinary curriculum. Most myopic children see well, both at a distance and near at hand, when their refraction is properly corrected; it is on grounds other than defective vision that they need special treatment. Some ophthalmic surgeons indeed doubt whether normal school work has any deleterious effect on their eyes. It is certainly right, however, to take special precautions during any stage of progression as shown by an increase of refraction of more than 1 D a year, by active ophthalmoscopic changes, by deterioration of vision, or by myopia high in relation to the age of the child such as −4 in a child of 6 or −6 in a child of 10. As to partially sighted children who are not myopic but have corneal nebulæ, congenital defects, or cataract, for example, it may be said that those with a visual acuity after correction of 6/24 or worse, with a near vision of J 8 or J 10, need special arrangements. To these may be added those with diseases liable to be progressive, such as optic atrophy and retinitis pigmentosa.

Owing to difference of opinion about the degree of myopia requiring special treatment, it is not really possible to give any estimate of numbers; but the report assumes that it is needed by something like 6000 children (myopes and non-myopes) in England and Wales. Of these about 2600 are already in schools for the partially sighted or in blind schools, and this means that some special educational provision is needed for rather more than 3000 others. The ways in which these children are now being educated and the improvements that ought to be introduced are fully discussed in the report. Special schools, or special classes in ordinary schools, are maintained by 22 different local authorities. Of these London has led the way, having 11 different schools or classes, while Liverpool has 6 special classes, all of them attached to ordinary schools. In sparsely populated areas there is much greater difficulty. For children whose disability is not great the ordinary schools can be used if individual attention is possible—this depending largely on the amount of interest taken in them by the headmaster and on the supervision of the ophthalmic surgeon. Sometimes the only alternative may be a blind school, but the committee hopes that the Board of Education will take immediate steps to require that schools for the blind should admit or retain partially sighted children only if special provision is made for their education by sighted methods. It further suggests that the Board might bring about a reorganisation of the residential blind schools so as to set aside some for partially sighted children only. Otherwise the children are taught by methods which will not fit them for post-school life, and on reaching the age of 16 they are turned out into the sighted world ill-equipped educationally and socially and bereft of the assistance which is available for registered blind persons. Special schools for the partially sighted are now supplemented by special classes in ordinary schools, and the report is largely concerned with the relative merits of these two systems. The special school involves segregation of the children from their sighted mates and the disadvantages of this are so great that in spite of administrative difficulties the committee leans decidedly to the plan of special classes in ordinary schools. Whenever possible, it feels, partially sighted children should be educated in classes forming an integral part of ordinary elementary schools. One objection to the special schools, as at present conducted, is that in most of them no difference is made in the educational treatment of myopes and non-myopes.

---

[1] The committee was appointed in 1931, and its report, just published and entitled "Partially Sighted Children," is obtainable from H.M. Stationery Office. 3s.

It is the duty of the ophthalmic surgeon, in the light of his periodical findings, to advise what modifications of the curriculum such as the extension or curtailment of close work or of physical exercises should be made in any particular case. Difficulty often arises over scholarships, but the surgeons consulted by the committee offer little or no evidence that the unrestricted curriculum of the secondary school has proved directly responsible for deterioration of vision of myopic children attending it; and the report maintains that if a child has gained a scholarhip to a secondary school the question whether he should be debarred for ophthalmic reasons from benefiting by it ought to be decided only on consideration of the circumstances and not according to rule. As to the curriculum itself, there are two subjects inviting comment. In the first place myopes in special schools are now commonly forbidden to read at all, and the committee wants to remove this restriction in the case of all but very high myopes or those with serious fundus changes or evidence of rapid increase of myopia. Others should be permitted to read any printed matter that is easily legible to them with their glasses at a distance of about 14 in., with the ordinary precautions against stooping. Secondly, as to physical exercises, at present there are certain restrictions on the syllabus for ordinary schools; for instance, skipping and jumping are forbidden, presumably because myopes are specially liable to detachment of the retina. Unless however there is high myopia, or myopia with fundus changes, this danger is so remote for children that it is legitimate to disregard it. Save in the circumstances just mentioned, the myopic child should be allowed to pursue the full physical training syllabus with the exclusion of exercises which involve sustained bending of the body forward and downward. For those with acute or subacute inflammation in the eyes (trachoma, obstinate phlyctenular disease, or interstitial keratitis) a special hospital school at Swanley is provided. The committee points out that a similar one for the north of England is badly needed.

ANNOTATIONS

THE CAMBRIDGE MEDICAL CURRICULUM

The end of the May term at Cambridge saw the final seal of approval set by the Regent House on the proposed alterations in the examinations for medical degrees. Details will be given in our forthcoming educational number, but it may be convenient to state here the main effect of the changes.

It will be remembered that as long ago as 1931 a syndicate was appointed to inquire into certain difficulties which had arisen and to suggest remedies. The University authorities were struck with the diminishing proportion of medical students who entered for the Natural Sciences Tripos. Whereas at one time almost all did so, soon after the war only 77 per cent. entered. Finally only 44 per cent. embarked on an honours course. The duplication of examinations was a factor in this: students felt it an unnecessary burden to take up for examination the subjects of anatomy and physiology both for the second M.B. and for the tripos. The first step proposed was therefore to exempt from the second M.B. those who reached a qualifying standard in these subjects in the tripos. The next was to include such subjects as general pathology and biochemistry in the first part of the tripos and not merely in Part II., which is only taken by the more advanced students. The syndicate's first report presented in June, 1932 (THE LANCET, July 30th, 1932, p. 256), and discussed by the Regent House in the following October, implemented these changes by the establishment of a Medical Sciences Tripos. This proposal aroused strong opposition on several grounds. Many considered it undesirable to segregate medical students from others working at natural sciences, and some feared for the prestige of the Natural Sciences Tripos if it were in effect thus divided. Others contested hotly that general pathology and biochemistry were subjects of vocational and not of educational value, but were not very convincing in their attempts to discriminate between the two.

The report was therefore referred back to the syndicate and a more acceptable solution was found. But the first report had not been fruitless; it brought out clearly the urgent need for change. Realising this, the Natural Sciences Tripos committee met the syndicate in a generous spirit, with the result that these changes have been accommodated within the four corners of the Natural Sciences Tripos. Another important alteration is that it is now compulsory for a medical student to attain a honours standard in some tripos, not necessarily the Natural Sciences Tripos, before he can proceed to the final M.B. examination. This at once raises the M.B. Cantab. to the status of a honours degree; those who do not wish to read for honours are not excluded, but they will have to content themselves with the diplomas as many now do. It is anticipated that insistence on the attainment of a honours standard in a tripos will reduce the number of rejections in the later M.B. examinations.

The normal course of events for a medical student at Cambridge will therefore run as follows: He can take his first M.B. examination either before or soon after entry. Organic chemistry will now be transferred from the second M.B. to form Part IV. of the first M.B. Physics and mechanics will be telescoped into one part, the remaining parts being inorganic chemistry and general biology. If a student fails to reach the required standard in anatomy and physiology in the Natural Sciences Tripos, or if he has taken some other tripos, he will have to pass a qualifying examination in the defective subject or subjects in the following October or December. If he entirely fails to reach a honours standard he must take the examination again as a qualifying test. The first part of the tripos can be taken at the end of the second or of the third year. Students will, however, be encouraged to take three years over their preparation for it, unless they are considered sufficiently good to proceed to the second part of the tripos. The remaining part of the second M.B., known to generations of students as "Bugs and Drugs," will disappear. An oral examination will be held in pharmacology, and optional questions will be set in that subject in the physiology papers of the tripos. It will be necessary to attend a course of instruction in pharmacology in Cambridge or at some other approved school. A separate examination in general pathology is held to be no longer necessary since it will be a subject of examination in the tripos and in the final examination. The net effect of this will be that a student who enters Cambridge having passed his first M.B. need have no examination beyond his tripos and an oral test in pharmacology until he reaches the finals. And it may be claimed that this change has been effected without in any way impairing the educational value of his training, but in effect enhancing it. All students entering the University from now on will come under these new regulations.

A good deal of unnecessary apprehension has been aroused in the minds of Cambridge medical graduates with regard to the changed regulations for proceeding to the M.D. As before, a thesis will be required, but it has been felt that, in the past, making the thesis the sole requirement has, in effect, discriminated unfairly against those engaged in practice compared with holders of laboratory appointments. The latter are in a better position to compose a thesis on academic lines than are the former. A candidate may therefore present a thesis either of such a standard as will exempt him from further examination or he may thereby establish a prima facie claim to be allowed to show clinical knowledge in the special branch with which his thesis deals. It is not intended to make it harder to obtain the M.D., but to make the conditions fairer for men whose clinical knowledge and experience entitle them to the higher degree.

POST-OPERATIVE PULMONARY COMPLICATIONS

PULMONARY complications continue to rank high in the list of the risks attached to major surgery. In a recent communication H. F. Griffiths[1] has analysed a large series of cases and has drawn some interesting conclusions about the pathogenesis of these complications. He finds that bronchitis and pneumonia occur no less commonly after regional or spinal anæsthesia than after the more commonly used general anæsthetics. At the same time he confirms the general belief that the incidence is largely confined to operations involving the peritoneal cavity, particularly when upper abdominal incisions are used. These facts indicate that it is the site of operation rather than the method of establishing anæsthesia that is mainly responsible. The real trouble, as has been suggested previously in these columns, seems to be that a patient with an abdominal operation wound will not cough if he can avoid doing so, and his bronchial secretions accumulate to set up infection. It is for this reason that, as Griffiths points out, hyperventilation induced by carbon dioxide does no good and may actually make matters worse, except in the comparatively rare cases of massive collapse of the lungs. Griffiths finds that the incidence of pneumonia is greater in the winter months, and that men are afflicted more commonly than women, possibly because they smoke more heavily. There seems to be little reason at present for hope that means will be found to prevent chest complications, since the only way to avoid a painful abdominal incision would be to avoid operating on the abdomen.

FROM THERAPEUTIC TO ACCIDENTAL MALARIA

THE Wagner-Jauregg treatment of general paralysis by inoculation with malaria has for some years been looked at askance by those who have foreseen in this practice the possibility of malaria becoming endemic in areas where it has hitherto been absent. A discussion occurred in July, 1929, at the Congrès de Dermatologie et de Syphiligraphie in Paris, when on the one side this issue was held to be impossible on account of the alleged absence of sexual elements in the blood of the inoculated patients, while on the other side experimental evidence was produced in controversion of this hypothesis. A disquieting, concrete contribution to the solution of this problem was made on May 15th of this year by Dr. R. Martin, Dr. Chassigneux, and Dr. Rouèssé in a communication to the French Academy of Medicine. The case they cited was that of a woman of 24, who had never left France, and who had lived uninterruptedly near Paris for several years. During August and September, 1923, she used to spend her evenings with her husband who worked as a labourer close to an asylum where the subjects of general paralysis were inoculated with *Plasmodium vivax*. She was often stung by mosquitoes, and in September both she and her husband suffered from a benign tertian fever which was promptly cured by quinine. When she had a second attack in April, 1934, *Plasmodium vivax* was found in her blood. While there can be no question of giving up such an effective treatment of general paralysis, it may well be asked if its practice is at present being safeguarded by all the desirable precautions. As pointed out at the French Academy on the occasion of this communication, the persons in charge of this treatment are assuredly experts in psychiatry. But they may be virginal neophytes in the realms of parasitology, ignorant or at least inadequately appreciative of the fact that the parasite of malaria may exist in the blood without provoking fever in its host. Also, on account of lacunæ in their knowledge, they may control the infection for which they are responsible so imperfectly that the patient harbours the malarial parasite for a year or more. The risk of malaria becoming endemic would be reduced if this treatment were to be centralised in institutions staffed by zoologists as well as by psychiatrists, and if the institutions themselves were not to be located in rural areas affording favourable conditions for mosquito life.

FLUORINE AND MOTTLED TEETH

Four years ago a mining community in Arkansas, U.S.A., abandoned an otherwise satisfactory water-supply on evidence suggesting that it was responsible for defective enamel formation of the developing teeth in children. The water was from a deep well and inquiry[1] by the U.S. public health service failed to establish the exact nature of the agent which caused the mottled teeth. It was not until later that a connexion was traced between the defect and the presence of fluorine in the water; in a review last year Dr. F. DeEds, of Baltimore, stated[2] that a daily intake of 0·1–0·15 mg. of fluorine per kg. of body-weight was sufficient to mottle the teeth. Cases had then been reported mostly from the western states of America and North Africa. Mottled teeth are now beginning to attract attention in this country. The *Analyst* for June contains a paper by Dr. Guy Barr and Mr. A. L. Thorogood. The National Physical Laboratory have recently examined samples of water from various localities in Essex sent them by Dr. N. J. Ainsworth, L.D.S., who discusses in the same issue the clinical significance of small quantities of fluorides in drinking water. Dr. Ainsworth had first observed mottled teeth in a young patient at Maldon, Essex, and then had gone on to examine a large number of Maldon school-children, when it became clear to him that the condition was identical with that described by Black and Mackay, in 1916, as occurring in many districts of the United States between the Mississippi and the Rockies, notably in Arizona. Dr. Barr's analyses showed that the water of areas where mottled teeth did not occur was free from fluorine, whereas water from the affected areas contained 4·5–5·5 parts per million. It seems clear from American experience that the substitution of deep-well water for that from shallow wells was a frequent antecedent of mottled teeth, some deep well water containing appreciable amounts of fluoride. Coagulation with aluminium sulphate followed by filtration will remove sufficient fluorine to render water harmless, the optimum pH for this reaction being 6·7 to 7·5, preferably near the lower figure. The amount of aluminium sulphate needed is rather large—from 17 to 34 times the fluorine present. The process of determination investigated and recommended by Barr and Thorogood is based on one described by de Boer involving the use of an alizarin-zirconium reagent which gives a pink to yellowish-brown colour with water containing fluorine. The technique described enables an amount of fluorine equivalent to 5 parts per million to be determined with an accuracy of 0·1 part. Maldon is one of the few places where there is a local industry of producing salt from sea-water, but there seems no reason to connect this fact with the occurrence of fluorosis, as Dr. Barr found that the proportion of fluorine to chlorine in sea-water was 170 times less in sea-water than in the positive well-water. The desirability of examining new sources of water-supply from deep wells by the method used by Barr or by some other trustworthy means is clearly indicated.

THE INTRADERMAL REACTION IN BRUCELLA INFECTIONS

There are an increasing number of reports by different workers on the failure to demonstrate agglutinins in the blood in cases of undulant fever. The reason for this is not clear. It may be that unsuitable strains are used for the agglutination test, or that the suspensions are rendered insensitive by the severe treatment with formol or other reagents. Or again it may be that the range of serum dilutions tested is so narrow as to fall within the pro-agglutination zone. These possibilities are mentioned in order that they may be taken into account before the definite conclusion is reached that agglutinins are absent. Whatever the explanation, there is undoubtedly some dissatisfaction with the agglutination test, leading many workers to make use of the intradermal allergic reaction. Though the antigen employed in this test was originally a filtrate of an old broth culture, it seems clear that a simple saline suspension of organisms from an agar culture is equally effective. E. Arbatskaia and H. Moroskin[1] record some results obtained with a brucella suspension heated to 70° C., and standardised to an opacity similar to that given by 2000 million *coli* per cubic centimetre. The intradermal injection of 0·1 c.cm. of this reagent gave rise in allergic patients to an erythematous reaction which became noticeable in 6–8 hours and reached its maximum in 24–48 hours. Besides the erythema there was a red, tender, indurated swelling, sometimes accompanied by a slight rise in temperature and enlargement of the axillary glands. Pseudo-reactions developed within a few minutes, but disappeared completely within 24 hours. Of 35 undulant fever patients tested, 21 gave a positive blood culture, 30 a positive agglutination, and 34 a positive intradermal reaction. Five patients with an absence of agglutinins reacted to the intradermal test, while only one patient with agglutinins gave a negative skin reaction. Non-specific positive reactions were observed in 11 out of 36 tuberculous patients, but when the strength of the bacillary suspension was reduced to 500 million per cubic centimetre, they no longer occurred. In their conclusions Arbatskaia and Moroskin recommend the use of a reagent of this strength in order to avoid occasional skin necrosis and non-specific reactions in highly sensitive patients.

While the interpretation of a positive agglutination reaction is fairly well understood, it is still doubtful what significance should be attached to a positive intradermal reaction. Is it, like the tuberculin reaction, a mere index that the subject has at some time or other been infected with the specific agent, or does it indicate that infection is active at the time? J. D. Goldstein[2] recently tested 253 unselected hospital patients in Rochester, N.Y., using a saline suspension of three-day liver agar slope cultures of *Br. abortus*, killed by heat at 60° C. for one hour, and standardised to 500 million per cubic centimetre. Twenty-six patients injected with 0·05 c.cm. of this reagent reacted positively. Of these, only five had an agglutinin titre of 1/80 or over, while 13 gave histories indicating possible sources of infection with *Br. abortus*. The conclusion drawn by Goldstein from these observations is that the intradermal test is of value in patients with undiagnosed pyrexia, and in afebrile patients without agglutinins whose symptoms may nevertheless be referable to a brucella infection. This conclusion may be correct, but it is certainly going beyond the facts. Far more information is yet required about the development, the intensity, and the persistence of a positive skin reaction in latent and in overt brucella infections before it will be justifiable to diagnose active infection on the basis of this reaction alone. Ample opportunity exists for survey work on the frequency of this reaction in exposed and non-exposed populations and in pyrexial and apyrexial patients.

RADIATION THERAPY IN CANCER

THE principles which should guide radiation therapy are being eagerly sought in every part of the world where this comparatively new weapon in the war against cancer is being tried. Many observers are devoting their attention to the quantity and equal distribution of the energy used, and to the study of biopsy material and of cancer tissue cultivated in vitro, with the object of noting the radio reactions induced by varying the doses and time-spacing, and establishing a more or less standardised dosage. Dr. Henri Coutard, as will be seen by those who read his lecture printed on another page, approaches the problem from a different angle. His work is based entirely on exceedingly careful observations of clinical facts. From these observations, proceeding step by step, he has been able to demonstrate that whereas in cancers of embryonic type the factor of intensity of irradiation is of chief importance, in the case of differentiated cell growths the time factor may be of equal or even greater importance. The modification of the vasculo-connective and general tissues resulting from the use of large daily doses with an intensity per minute exceeding 5 r would not be of great importance in the embryonic type of cancer; but the same daily doses with the same intensity per minute would, generally speaking, entirely defeat their object if applied to the treatment of highly differentiated cancers. These contrasting results are thought to depend upon the specificity of the cell reaction to radiation. In the embryonic radio-sensitive type of cancer the cells are held to be destroyed directly by the intensive dose, and therefore the end-result is not affected by the modification of the supporting tissues; whereas in the case of tumours of the resistant, differentiated type, only those cells actually in mitosis are damaged early, and the final destructive effect of the irradiation is believed to depend upon the gradual maturation of the remaining cells. This effect does not materialise when the vasculo-connective tissue is substantially altered by the intensity of the daily dose; on the contrary, instead of the malignant cells becoming more sensitive, a condition of radio-resistance is produced in them. According to Coutard, avoidance of damage to the supporting tissues is therefore essential: only a slight reaction is permissible if a good end-result is to be obtained.

Having at first completely failed in the treatment of certain types of cancer, Coutard made careful observations on surface tumours, varying the daily dose and intensity. He was finally able to demonstrate that by using small daily doses of low intensity, and lengthening the total duration of treatment, success could be obtained even in radio-resistant tumours. Using this method he has achieved good results even in infiltrating cancers of the larynx. He finds that the tumour response and radiation tolerance of the vasculo-connective tissue differs in individual cases and cannot be determined in advance; he holds, therefore, "there exists no fixed method of treatment but a simple clinical treatment for each individual patient and for the special type of tumour." The laborious technique carried out at the Fondation Curie involves the concentrated attention of highly skilled workers, and on account of the length of time necessary for the treatment of each case and the quantity of apparatus required can only be carried out at special centres. Even if the particular technique used is not practicable in institutions where large numbers of patients have to be treated and relays of skilled workers are lacking, the facts ascertained at research centres such as the Fondation Curie are of the utmost value. Radiological treatment is still at an experimental stage, and premature attempts at standardisation of dosage are to be deplored. Only by developing centres for clinical study in close coöperation with research laboratories are we likely to make the best possible use of the powerful but dangerous weapon to our hand.

THE BROAD TAPEWORM IN DOG AND PIG

THE presence of *Diphyllobothrium latum* in North America has excited a good deal of interest,[1] and, according to H. B. Cushing and H. L. Bacal,[2] its incidence is increasing in Montreal. The number of patients attending three hospitals in this city for this infection between 1906 and 1928 was 13, and between 1929 and 1933 was 37, 12 of them attending last year. As to the fish which harbour the plerocercoid stage infective for man, no instance of infection was found in those caught in the St. Lawrence river; it was limited to those imported from the Great Lakes during the months when the river fish are out of season. But interest in this matter is being taken in Russia also, and the work which is being done there has not led to the same conclusions as have been drawn in America. It may be recalled that in commenting on the findings of Thomas B. Magath and Hiram E. Essex[1] (that in only 1·5 per cent. of eggs of this tapeworm passed by the dog was there development of the coracidium which infects the first larval host) we emphasised the fact that since dogs may harbour many adult worms they may pass many eggs, so that these may tend to make up in quantity what they lack in infective quality. Investigation by Wictor Tarassow[3] shows, however, that such a poor potential infectivity as this is no necessary attribute of eggs from the dog. True, these develop more slowly than do those from man, for in 14 to 16 days the coracidium has appeared in 7·8 to 9·2 per cent. of eggs from the dog as against 72 to 73 per cent. of those from man; but after 21 to 25 days the figures are just over 50 from the dog and just over 75 from man. Quite clearly it cannot be taken for granted that the dog is a negligible factor in the spread of this tapeworm to man. In this respect Tarassow has implicated the pig also as a definitive host alternative to man. He himself swallowed, and he fed to each of two pigs, six plerocercoids, the stage in the pike infective for the definitive host, and in all three instances two adult worms developed. He next dissected 15 swine from four different villages. In three of the villages fish were eaten and the offal thrown to pigs, and 8 of 11 of these harboured the broad tapeworm; in the fourth village fish was not eaten and none of 4 pigs was infected. Prophylactic measures against this worm must be given a considerably wider range than has hitherto been generally realised.

ANOTHER GENERAL ANÆSTHETIC

READERS of Dr. Bourne's paper on cyclopropane in obstetrics (p. 20) will be interested to hear of a brief article on the drug which appears in the May number of the *Magazine* of the University of Leeds Medical Society. The author, Dr. W. Stanley Sykes, has used cyclopropane so far in only a few cases, but his experience has been very satisfactory. Obviously it has great merits as a gaseous anæsthetic. It is as innocuous as nitrous oxide so far as effects on blood chemistry and on internal organs are concerned, yet it is far more potent and gives better muscular relaxation. The practical drawback to its wide employment is the high cost of its production. This obstacle is overcome, however, when well-constructed machines are used for its administration, these comprising a carbon dioxide absorption chamber, so that the cyclopropane can be breathed over and over again. The drug is now being investigated in this country under the auspices of the Anæsthetics Committee (Medical Research Council and Royal Society of Medicine) and we shall be surprised if in the future it does not secure an important place among general anæsthetics.

MECHANISM OF RELIEF OF CHEST PAIN AFTER THYROIDECTOMY

COMPLETE thyroidectomy, which is now being undertaken extensively in America for patients with angina pectoris and congestive heart failure,[1] has now been found by Weinstein, Davis, Berlin, and Blumgart[2] to relieve immediately chest pains not associated with exertion, and the skin hyperæsthesia and tenderness of the deeper tissues of the chest wall not uncommonly found in cases of chronic heart disease. The more permanent relief of angina and of the symptoms of severe heart failure which results from the removal of the normal thyroid usually sets in only some weeks after operation, at a time when the basal metabolism has undergone considerable reduction. The immediate relief of symptoms cannot be explained by the reduction of basal metabolism, and the authors suggest that the relief is due to interruptions of nerve impulses from the heart resulting from the operation, and is comparable to the effect of cervical sympathectomy. In three anginal cases in which hemithyroidectomy was done as a preliminary, exertion taken within two weeks of the operation produced anginal pain only on that side of the chest corresponding to the thyroid lobe left in situ. Between the second and eighth weeks after operation pain was again felt on the operated side, but after a second operation to remove the remaining part of the gland, and when the metabolic rate had fallen considerably, there was permanent relief from angina. The thesis set out is thus that of a double mechanism—the immediate temporary relief of chest pains and tenderness after complete thyroidectomy being due to the interruption of different impulses from the heart at the time of operation, while permanent relief is dependent on the reduced work of the heart associated with the development of the hypothyroid state.

"MEN IN WHITE"

THE reading-room of the staff club at "St. Jude's Hospital" is not a restful place, and the resident staff who appear in Sydney Kingsley's play at the Lyric Theatre lead anything but restful lives. Loud speakers throughout the hospital keep calling attention to the fact that George Ferguson, F.R.C.S. (the hero), is wanted on the telephone; and this leads his fiancée to put her foot down and demand that he shall take surgery rather less exclusively after his approaching marriage. The conflict between love and a career is thus set going in earnest, and she finds a strong antagonist in a senior surgeon (excellently played by Mr. Lewis Casson) who wants Ferguson to abjure easy practice and serve a long and stern apprenticeship to his profession. A scene in which the young man disobeys a physician's orders and thereby saves a child's life at once endears him to the audience, and he retains our sympathy and respect through the appalling complications that arise from his relations with a young probationer nurse. These lead to a scene in the operating theatre which borders on the improbable but includes a striking exhibition of routine aseptic and antiseptic precautions. The technical side of the play is, indeed, almost beyond criticism, and Mr. Robert Douglas as Ferguson gives a consistent and convincing performance; but even after being anglicised by Dr. "Merton Hodge" the story remains faintly transatlantic in tone. Apart from the behaviour of the hospital board of governors, there was little in the play that could be called enlivening; and though many people will enjoy the chance of seeing behind surgical scenes, the central problem really makes less impression than the ingenuity with which a special department of life is presented.

Surg. Rear-Admiral R. W. B. Hall, C.B., O.B.E., has succeeded Surg. Vice-Admiral Sir Reginald St. G. S. Bond, K.C.B., as Director-General of the Medical Department of the Navy.

Dr. Robert Hutchison has been elected president of the Royal Society of Medicine for the coming year. The names of the new presidents of sections will be found in our news columns.

THE death is announced, as having occurred on Wednesday, of Madame Marie Curie, the joint discoverer with her husband of radium.

IT is announced that Mr. Edward William Meyerstein has given £70,000 to the rebuilding scheme of the Middlesex Hospital, bringing his magnificent benefactions up to the sum of £100,000.

WE regret to announce the death on Tuesday last of Sir James Kingston Fowler, consulting physician to the Middlesex Hospital and well known both for his work in relation to tuberculosis and as an authority on medical education.

THE LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.—Applications are invited for the Wandsworth scholarship, which will be vacant in October. The scholar must undertake research in tropical medicine and will be expected to spend a substantial part of his time overseas. Further particulars will be found in our advertisement columns.

PROGNOSIS

A Series of Signed Articles contributed by invitation

IX.—PROGNOSIS IN SURGICAL TREATMENT OF PEPTIC ULCERS

"Out of this nettle, danger, we pluck this flower, safety."

THE public have long known what many surgeons have failed to grasp, that no operation is free from danger and risk of life. What every patient wants to know is the extent of this risk and the chances of ultimate cure; and yet of all branches of surgery this is the most uncertain. To be analysed and fully appreciated the results of operation have to be put in a statistical form, but when so expressed they are dependent upon so many factors that they will seldom remain undisputed. The most important duty of a surgeon is to know when not to operate, for patients who can be cured medically should never be subjected to operation; but the inclusion of many of these milder cases will do much to improve the surgeon's statistics. If surgery be imperative the wise choice of operation will not only give a lower operative mortality-rate but a higher percentage of ultimate cure, but in some cases unsatisfactory end-results compel the rejection of a relatively safe operation for one carrying a rather higher risk. Above all, the results of any one operation will largely depend upon the surgeon who performs it. One surgeon may perfect one method, another a second. Hence it is impossible to state that any one operation performed for a certain lesion will universally be followed by a given percentage of deaths or cures. Only by the study of a large series of his own cases is the surgeon able to inform his patients of the results they may expect from the procedure he advocates.

In the present article the selection of cases for surgical treatment cannot be discussed. The results are based upon a study of 1805 operations personally performed. The patients had all previously been treated medically but only 1727, which have been followed for periods of 1–21 years, are analysed.

PYLORIC AND DUODENAL ULCERS

The commonest type of peptic ulcer is that in the duodenum. At times such ulcers may extend in part beyond the pyloric vein on to the stomach and since my own experience has been that such may occasionally be followed by carcinoma, a complication which does not follow a true duodenal ulcer, they have in my own series been analysed separately. Their treatment, however, is identical and therefore for present purposes they will be considered together. Generally speaking three methods of treatment have been advocated: (1) gastro-duodenostomy, with or without excision of the ulcer; (2) gastro-enterostomy, anterior or posterior; and (3) partial gastrectomy. It is in the choice of these operations that so much divergence of opinion has been expressed by different surgeons.

It has been claimed that gastro-duodenostomy allows of direct attack upon the ulcer and is not followed by gastro-jejunal ulceration, and that partial gastrectomy, by permanently lowering the acidity, almost entirely abolishes the later onset of gastro-jejunal ulceration. It is by perfecting the technique of one or other methods that different surgeons have obtained such varying results. My own choice on both theoretical and practical grounds has been for gastro-enterostomy. By firmly embedding the ulcer the dangers of hæmorrhage and perforation are overcome, while the gastro-enterostomy is a safe procedure with very good end-results. The risk of operation should never be above 2 per cent., whereas the published statistics of partial gastrectomy even in the case of its most skilled exponents lies in the neighbourhood of 6 per cent. The danger of subsequent marginal ulceration in my own cases has been rather over 3 per cent., so that the mortality of gastro-enterostomy together with the subsequent incidence of marginal ulceration is less than the mortality of partial gastrectomy, which in my opinion should be left for those cases that later do develop such ulceration.

In my own series there were 784 cases of uncomplicated ulcers in this situation treated by gastro-enterostomy. The mortality was rather under 2 per cent. and it included a consecutive series of 283 cases without a death. When it is remembered that these are all patients who had been seen by a physician and treated by medical methods it will be realised that in such a series the risk to life from perforation or hæmorrhage, if no operation had been performed, would probably have been considerably higher than this.

A number of the patients in the series who had been watched for not less than five years were carefully investigated for the collective investigation of the British Medical Association[1] and this investigation showed that 84·9 per cent. of them were completely cured. Many of these patients were working men of the hospital class who, owing to the nature of their work, were unable to take any dietetic precautions and yet remained free from all trouble. Of the total group of 784 cases, 26 subsequently developed gastro-jejunal ulcer and this complication necessitated further operation. Six at a rather later date showed the onset of carcinoma. However, in 3 of these the carcinoma only occurred after a long period and at a site remote from the ulcer and therefore were not related either to the ulcer or to the operation. It is true that the condition would have been prevented by a partial gastrectomy, but this is no more reason to advocate that measure than it would be to perform it in normal people as a preventive of subsequent carcinoma.

My own views therefore are that cases of duodenal ulcer should be treated medically in the earlier stages. For the resistant, progressive, or complicated cases gastro-enterostomy is the operation of choice. When so treated about 85 per cent. will be completely cured. The mortality will not be more than 2 per cent., gastro-jejunal ulceration will occur in about 3·3 per cent., and about 0·7 per cent. will later develop carcinoma of the stomach. In none of the cases so treated in my series did a severe anæmia supervene.

Gastrectomy.—Since for the above reasons my own choice is for gastro-enterostomy combined with embedding the ulcer, there are in this series only a few cases treated by partial gastrectomy, the method being advocated only for those patients who showed a very high acidity or where there was some other complication. Of the 20 patients so treated two died, and one developed a gastro-jejunal ulcer. There were no examples of subsequent carcinoma or profuse anæmia. There were also only 15 cases treated by gastro-duodenostomy. But here again a fair comparison cannot be drawn; they were all unusual or complicated cases and the real value of this operation can only be obtained from the figures of those surgeons who use the method frequently, and a discussion of such figures would be out of place in this communication. Of the 15 cases two died, but in the survivors there were no complications.

---

LESSER CURVE ULCERS

It is now universally accepted that many such ulcers are cured medically and therefore the results of operation, as discussed here, only apply to those cases where this treatment has been tried, or to cases referred by a physician for surgical treatment. For this lesion there is an increasing tendency to choose *partial gastrectomy*. This is especially so on the European Continent where practically no other operation is performed and the practice shows some signs of spreading to this country. As already mentioned, even in the hands of the most expert exponents of this operation, the mortality is in the region of 6 to 8 per cent. Moreover it would seem to be theoretically incorrect to remove some three-quarters or seven-eighths of the stomach in order to excise a small chronic ulcer which may be only one or two centimetres in diameter. It is therefore my custom to treat these cases by one of three methods, according to the nature of the ulcer.

Wedge resection, with temporary occlusion of the pylorus and gastro-enterostomy.—All small ulcers in the middle of the lesser curve which are manifestly benign in nature are treated by this method.

The ulcer is excised by a wide wedge after the arteries have been tied, or more rarely destroyed by the cautery. The opening so formed is sutured, the pylorus occluded temporarily with a running silk suture and a gastro-enterostomy performed, the stoma running parallel to the greater curve and so placed that one-half lies proximal and one-half distal to the line of suture of the wound of excision.

In my own series 310 patients were so treated with 13 deaths, a mortality of 4·2 per cent., and in a group which were watched for a minimum of five years there were 88 per cent. complete cures. Of the total, six, two of which were excised by the cautery, developed recurrent ulcers and five showed the later onset of carcinoma. There was one case of severe anæmia following the operation.

Partial gastrectomy.—In some cases where the ulcer is large and adherent to the pancreas or there is much surrounding induration, a wedge resection would necessitate the removal of so large a portion of the stomach that considerable deformity would result.

In this type of lesion and in all those in which there is the slightest suggestion, either in the symptoms or in the appearance at operation, of the presence of early carcinoma a partial gastrectomy should be performed. The drawback of this operation lies in its somewhat higher operative mortality, but in spite of the theoretical objections to the removal of so much healthy stomach, the end-results, with the exception of the relatively small danger of the onset of severe anæmia, are remarkably good.

In my own series there were 240 cases of chronic ulcers so treated with 30 deaths, a mortality of 12·5 per cent. This is considerably higher than many published series, but the method has only been used for the larger and more serious ulcers. There were no examples of recurrent ulceration or of the onset of carcinoma, but four later developed severe anæmia. In the series watched for a minimum of five years 70·2 per cent. were completely cured, the figures being lower than the last series owing to the higher primary mortality.

Gastro-enterostomy.—In some cases the ulcer is so large or is situated so high up on the lesser curve that either a complete gastrectomy would be necessary or the partial gastrectomy would be so extensive and difficult that it would carry with it a high mortality.

In such cases it is my custom to perform a gastro-enterostomy as a palliative operation. Should carcinoma be present the relief will of necessity be only temporary, but even a partial gastrectomy in such conditions would be certain to be followed by recurrence. *In about 40 per cent.* of the cases a cure will result, while in the remainder the ulcer will persist but usually becomes *so much smaller* that an excision becomes possible at a later date. Some of the patients are gravely ill, so that even so simple a procedure is associated with a relatively high mortality.

In my own series of 17 cases there were five deaths. There were also five cases in which the ulcer persisted *and a second operation* was necessary. It may be said then that of all surgical ulcers of the body of the stomach which are treated by methods varying with the nature of the lesion the total mortality will be approximately 7·5 per cent. Some 80 or 85 per cent. will be completely cured, 1·7 per cent. will develop recurrent ulceration, about 1 per cent. will show the *onset of profound anæmia at a later date*, and less than 1 per cent. will develop subsequent carcinoma.

ULCERATION WITH SEVERE HÆMATEMESIS

The most difficult class of case to treat is that of severe hæmatemesis from peptic ulceration. There is *no doubt that many such cases die if treated* medically, but on the other hand, they are very bad subjects for surgical interference, even if the operation be preceded by a blood transfusion. As a general rule the diagnosis between hæmorrhage from an acute or chronic ulcer is not difficult, but at times the patient is so seriously ill that an accurate history cannot be obtained, and since hæmorrhage from an acute ulcer usually abates under medical treatment, the decision is one of considerable importance. In actual practice no hard-and-fast rule can be made. To treat all cases of severe hæmorrhage surgically would lead to a high mortality, but if surgical treatment be denied to the patient many lives will be lost. Every case therefore must be regarded as a problem in itself, a problem in which each surgeon may hold opposing views. It thus becomes almost impossible to give a prognosis which in any degree approaches accuracy. The mortality is of necessity high, for only those cases will be selected for operation which it is thought will die if left. The *nature of the operation* will also vary in the hands of different surgeons. A bleeding duodenal ulcer can nearly always be controlled by embedding the ulcer and completely occluding the duodenum, and then performing a gastro-enterostomy; but for gastric ulcers the operation may consist of exposing the ulcer and ligating the bleeding points, ligating the arteries passing to the ulcer, [illegible] even performing a partial gastrectomy. In my own series there were 50 cases treated surgically and the mortality was between 20 and 25 per cent., *but it is impossible to estimate how many of these cases would have died without operation.*

PERFORATED ULCERS

Whereas in the last group of cases discussed the surgeon's difficulty lies in coming to a decision whether to operate, in this group there is no such difficulty. In the presence of so grave a disaster practically every patient will die if no operation be undertaken, and therefore it is the surgeon's duty to operate even if only 1 per cent. of the patients can be cured. Fortunately, with the growth of knowledge and a realisation of the importance of early operation the *dangers of perforation* have been enormously decreased. In my own series, as in every one published, the importance of the *time factor is manifest* and more credit is due to the practitioner who makes an early diagnosis and insists upon immediate *operation* than to the surgeon who performs the operation. In cases operated upon within the first twelve hours the mortality should not be greater than 5 per cent., and the fall in the mortality of the more recently published series is almost wholly due to the inclusion of a larger number of cases treated in this period. Recently published series show a total mortality of not more than 15 per cent. as compared with the 50 per cent. to 60 per cent. of a few years ago. The question as to whether the operation should consist of a simple suture, or whether this step should be combined with a gastro-enterostomy or even whether a partial gastrectomy should be performed, is one which has led to considerable dispute. The surgeon must always keep in mind that his first duty is to save the life of the patient and the possibility of subsequent trouble becomes of relatively minor importance. If he feels that the patient's condition is quite good, that the perforation has been recent, and that he can perform a gastro-enterostomy in a few minutes, he may be wise to carry out this step at the first operation, but if he is at all dubious he should be content with a simple suture, if necessary combined with drainage; but in such cases the patient must always be carefully watched afterwards and if the ulcer persist a second operation undertaken at a later date.

A. JAMES WALTON, M.S., F.R.C.S., B.Sc.,
Surgeon, London Hospital.

SPECIAL ARTICLES

EPIDEMIOLOGICAL SIGNIFICANCE OF THE SEROLOGICAL TYPES OF PNEUMOCOCCI

BY IAN M. CHRISTIE, M.D. Glasg., D.P.H.
LATE RESIDENT ASSISTANT PHYSICIAN, KNIGHTSWOOD FEVER HOSPITAL, PUBLIC HEALTH DEPARTMENT, GLASGOW

THIS paper describes a study of the incidence of the different types of pneumococci in patients and nurses in Knightswood Fever Hospital from April, 1932, to May, 1933. The nursing staff was taken as a selected healthy community, and examinations as to the type of pneumococcus present were made on each nurse at least once a month. The findings recorded are those obtained by repeated examination of 100 healthy adults for varying lengths of time during the 13 months of the investigation, the average period of observation being eight or nine months and the minimum four months. The method employed throughout was the intraperitoneal injection of mice with sputum or mucoid material from the back of the throat, and subsequent typing by means of appropriate antisera. Before proceeding to a discussion on these points it is necessary for the proper appreciation of the significance of changes in the nasopharyngeal pneumococcal flora of the persons examined to include a brief description of the prevalence of acute respiratory diseases in Glasgow and the type of pneumonia admitted to hospital during the period of study. The findings of the investigation are then submitted with reference to, first, the Group IV., then Types I. and II., and lastly, Type III. pneumococci.

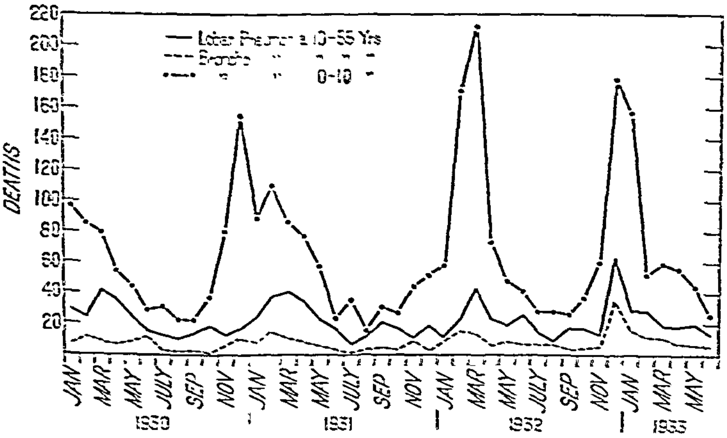

FIG. 1.—Deaths from acute respiratory disease in Glasgow (1930–33).

PREVALENCE OF ACUTE RESPIRATORY DISEASES IN GLASGOW FROM JANUARY, 1930, TO JUNE, 1933

These epidemiological happenings are illustrated in Fig. 1, in which is set forth the deaths notified each month as lobar pneumonia and broncho-pneumonia in the age-period 10–55 years, and also the number of deaths from primary broncho-pneumonia under the age of 10 years. The first two graphs were chosen because of the fact that the age-group 10–55 represents the period of predilection for lobar pneumonia, the corresponding figures on the incidence of deaths from broncho-pneumonia in adults being included for the sake of contrast. The third graph gives the number of deaths notified as acute primary broncho-pneumonia in children which is a much less easily definable class. It is necessary to point out that the course of these different respiratory infections was complicated by an outbreak of influenza which occurred in Glasgow in December, 1932.[1] With regard to the curve of deaths for lobar pneumonia, it will be noted that the disease occurred in periods of high prevalence at regular intervals of approximately 12 months. In the years 1930–32 the highest level was always in the month of March, but the fourth elevation occurred three months earlier than was customary and coincided with the outbreak of influenza in December, 1932. The two periods of high prevalence of lobar pneumonia in 1932 were in the nature of explosive outbreaks, there being a sudden rise to a peak level followed by a more gradual fall. They contrast markedly with the curves of incidence in 1930–31, when there was a broader and more sustained graph. The curve of broncho-pneumonia in adults, apart from a gentle rise each spring, ran a very even course until December, 1932, when it participated in the sudden rise of acute respiratory disease associated with the influenza epidemic. The incidence of deaths notified as acute primary pneumonia in children is of particular interest. In 1930–31 there was no definite association with the curve for lobar pneumonia, but in 1932 there was a complete change, the curve of deaths from acute pneumonia in children corresponding exactly with the two epidemic periods of lobar pneumonia and this prevalence in children being much more intense than the incidence in adults.

TYPE OF PNEUMONIA ADMITTED TO KNIGHTSWOOD HOSPITAL

The present inquiry was begun in the spring of 1932, when the epidemic of lobar pneumonia was in progress, and was continued throughout the period of influenzal prevalence which occurred at the end of the year. As was mentioned above, the influenzal outbreak was accompanied by a high incidence of lobar penumonia,[2] and it is of interest to note that a marked alteration in the types of infecting pneumococci was observed in the cases admitted to hospital at that time.[3] This is illustrated in Table I., which sets forth the frequency and fatality percentages of the cases during the two periods.

TABLE I

A Comparison of the Incidence and Type of Lobar Pneumonia admitted during Two Epidemic Periods of Pneumonia and Influenza Respectively

—	Lobar pneumonia period. Feb.–June, 1932.				Influenza period. Dec., 1932–Jan., 1933.			
	Cases.	Deaths.	Frequency (per cent.).	Fatality (per cent.).	Cases.	Deaths.	Frequency (per cent.).	Fatality (per cent.).
Type I. ..	47	12	42·0	25·5	14	1	23·3	7·1
Type II. ..	41	10	36·6	24·4	32	12	53·3	37·5
Type III. ..	2	2	1·8	100·0	7	3	11·7	42·6
Group IV. ..	22	1	19·6	4·5	7	—	11·7	—
Total ..	112	25	—	22·3	60	16	—	26·7

The Table demonstrates how the incidence of Type I. pneumonia fell from 42 per cent. in the first period to 23·3 per cent. in the second period, with an accompanying diminution in mortality of 18·4 per cent., whereas the incidence of Type II. infections rose from 36·6 to 53·3 per cent. with an increase in death-rate of 13·1 per cent. The Type II. infections during the influenza period were severe at all ages, and the excess of Type II. over Type I. illnesses persisted throughout the first six months of 1933. The frequency percentages for Type III. pneumonia showed a very marked increase which was accounted for by these infections occurring in elderly people already weakened by concurrent influenza.

It might appear then that the outbreak of influenza not only precipitated the seasonal prevalence of lobar pneumonia, but initiated a very marked alteration in the character of the infecting pneumococcal types.

The salient points elucidated may be summarised as follows: (*a*) During the year 1932 lobar pneumonia occurred in epidemic form on two occasions. (*b*) Both these periods of epidemic prevalence were accompanied by corresponding epidemics in children. (*c*) The second epidemic period coincided with an outbreak of influenza in the city, and was associated with a marked alteration in the character of the infecting pneumococcal types. (*d*) In the years 1930–31 a high incidence of lobar pneumonia occurred in the spring months, but epidemic features were not so prominent, and the inter-relationship between the incidence of the disease as it occurred in the adult and in the child not so apparent.

Group IV. Pneumococci

The behaviour of these organisms in the nursing staff during the two epidemic periods is illustrated in Fig. 2, which shows, that along with and following the high incidence of lobar pneumonia in the spring of 1932, there was a correspondingly high percentage of Group IV. pneumococci. This incidence of Group IV. organisms tended to follow the case incidence of lobar pneumonia. There was a fall in the Group IV. curve from 71 per cent. in April to 27 per cent. in August, after which the carrier-rate gradually rose to 38 per cent. for December. In January the curve fell to 31·5 per cent., but rose to a peak of 48 per cent. in March, dropping to 36 per cent. in April. The incidence of the Group IV. organisms thus showed a considerable degree of fluctuation, a feature which is not in accordance with the findings of some other observers. Rosenau, Felton, and Atwater [4] recovered pneumococci from samples of the community in proportions around 90 per cent., with only a moderate degree of variation. Cruickshank [5] also found the percentage of pneumococci in the throats of inmates of a mental institution to be constantly between 92 and 100 per cent. On the other hand, the report [6] on a study of the nasopharyngeal bacterial flora of a group of the Manchester population, over the period July, 1925, to September, 1927, states that "the fluctuations in the pneumococcal carrier-rate were curious and unexpected."

The incidence of the Group IV. organisms in the 100 nurses comprising the selected healthy community showed a marked difference in the results obtained by one exmination of each person as compared with those obtained by repeated examinations, a fact which is brought out in Table II.

TABLE II

Incidence of Pneumococci in 100 Healthy Persons

Types of pneumococci isolated.	Results obtained by—		
	Single examinations.		Repeated examinations.
Group IV.	40	55 per cent.	85
Type III.	9		17
Type II.	4		15
Type I.	2		8
Nil	45		15

It will be seen that the percentage of pneumococci isolated by a single examination of each person was 55, Group IV. organisms accounting for 40 per cent., but by means of repeated examinations Group IV. organisms were recovered from as many as 85 per cent. of the series. The occurrence of Group IV. organisms in individual nurses showed that persistence of the organism in any one person was not a common feature. In a minority of cases the organisms were recovered on successive examinations over a period of five to eight months, but generally the carrier state was markedly intermittent in character.

To obtain further information as to the significance of these Group IV. organisms, 36 strains were typed by means of antipneumococcal sera for Types IV.–XXXII., the antisera being kindly supplied by Miss Cooper,[7] of the Bureau of Laboratories, Department of Health, New York. The proportion of Group IV. strains classified by means of the additional antisera is contrasted with a further series isolated from (1) adult convalescents in pneumonia pavilions and (2) adults and children suffering from acute pneumonia, the results being set forth in Table III.

TABLE III

Proportion of Group IV. Strains Typed by Antisera IV.–XXXII.

Source of strains.	Examined.	Strains that typed.	Strains that remained unclassified.
Healthy persons ..	36	17	19
Adult convalescents ..	36	20	16
Acute pneumonia ..	28	16	12
Total	100	53	47

It will be seen that by means of these additional antisera 53 per cent. of the series were further classified. In all 18 different types were isolated and the incidence of these is demonstrated in Table IV.

TABLE IV

Incidence of 53 Group IV. Strains Classified by Antisera IV.–XXXII.

Type of pneumococcus.	Number typed.	Type of pneumococcus.	Number typed.
IV.	6	XV.	1
V.	2	XVI.	2
VI.	10	XVII.	1
VIII.	5	XVIII.	1
IX.	2	XX.	4
XI.	2	XXI.	6
XII.	2	XXV.	1
XIII.	2	XXXVIII.	2
XIV.	3	XXX.	1

Apart from the Type VI. pneumococcus the different types were uniformly distributed. A Type VI. pneumococcus was isolated on ten occasions, six occurring in infants with acute broncho-pneumonia, three in adult convalescents, and one in an adult with broncho-pneumonia.

Some interesting points were noted in dealing with these strains. The degree of significance to be attached to the recovery of Type VI. pneumococcus from the throat was variable. In a child with acute pneumonia a Type VI. strain and a pneumococcus unclassified by sera IV.–XXXII. were isolated from the throat on two separate examinations during the acute phase of the illness. Two weeks later the child developed an empyema, from the pus of which Type I. pneumococci were obtained. On the other hand, in a fatal broncho-pneumonia in a child of two and a half years with mild conjunctivitis and otorrhœa, Type VI. organisms were isolated not only from the throat but also from the conjunctival and aural discharges. It is probable that in the first case the organisms appeared as temporary parasites, and that in the second they were the real cause of the illness. A noteworthy finding was recorded in a child of six months. At the onset of an acute broncho-pneumonia a Type XIV. pneumococcus was isolated. Ten days later, when the illness was at its height, a second examination was made with the result that well-marked agglutination occurred with every type antiserum from I.–XXXII. One other feature was the tendency for neighbouring types to be isolated at one time; Types XXVIII. and XXX., Types XIII. and XIV., and Types XX. and XXI. being isolated from individuals living in close association. Regarding the unclassified strains, 12 were isolated from cases of acute pneumonia, of which 6 were lobar and 6 broncho-pneumonic in character. The remaining 35 were recovered from convalescents and healthy persons.

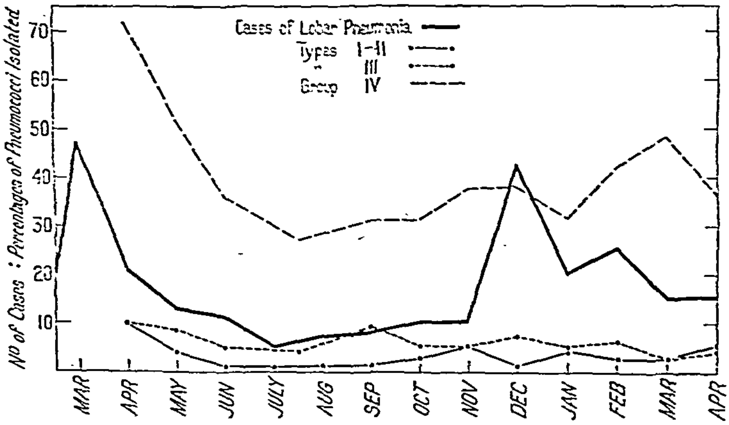

FIG. 2.—This chart shows the number of cases of lobar pneumonia (thick black line) in Knightswood Hospital from March, 1932, to May, 1933; and also the percentage of nurses harbouring pneumococci of various types during the same period.

Types I. and II. Pneumococci

From Fig. 2 it will be observed that the carrier-rate of Types I. and II. pneumococci in the nursing staff was as high as 10 per cent. in April, 1932, following the first epidemic period, but remained continuously between 1 and 5 per cent. throughout the rest of the investigation. The distribution of these organisms is illustrated in Table V., in which is presented a comparison of the pneumococcal flora in the throats of 60 nurses during their period of training in pneumonia pavilions; with that obtained from a control series consisting of 75 nurses who had not previously served in these wards.

TABLE V

Incidence of Pneumococci in the Throats of 60 Nurses in Pneumonia Pavilions and 75 in Control Wards (April, 1932, to May, 1933)

Types of pneumococci.	Pneumonia wards.		Control wards.	
	Positive.	Per cent.	Positive.	Per cent.
I. ..	8	13·3	—	—
II. ..	13	21·7	2	2·7
III. ..	7	11·7	11	14·7
IV. ..	53	88·3	59	78·8

The figures were obtained by means of repeated examinations, and they clearly demonstrate how, with two exceptions, the incidence of the Types I. and II. pneumococci was confined to nurses serving in pneumonia wards.

In these wards 21 nurses proved to be carriers of Types I. and III. pneumococci at one time or other, whereas, in the control series, there were only two Type II. carriers who were stationed in diphtheria and scarlet fever pavilions respectively. During the first half of the study there was an equal number of Types I. and II. carriers, but in the second portion when a preponderance of Type II. infections occurred there was an increased proportion of Type II. carriers. Two nurses proved to be persistent carriers of these organisms for periods of three and five months respectively, but otherwise the carrier state was short-lived.

The feature of these results is that the case of lobar pneumonia is the source of spread of the two chief pathogenic types and that nurses in attendance on such cases are liable to become carriers of these organisms, usually for a short space of time, but without any apparent danger to themselves or to others. The significance of this is increased by the fact that a similar incidence of Types I. and II. pneumococci was found among patients in pneumonia wards admitted with conditions other than Type I. or II. pneumonia, and it is evident then that in this particular pneumonia pavilion there was a continuous frequency of Types I. and II. pneumococci for a period of at least one year; and that a not inconsiderable number of patients admitted with conditions other than pneumonia together with the nurses on duty in these wards were exposed to this high concentration of Types I. and II. pneumococci, and yet in no instance did any of these persons develop a pneumonia due to these types.

Type III. Pneumococci

The behaviour of the Type III. pneumococcus as a nasopharyngeal parasite in the community is of peculiar interest. Avery and others[8] in 1917 *recorded the percentage of Type III. pneumococci* among normal persons in New York to be as high as 28 per cent., but in this country the incidence has usually been *estimated between 5 and 10 per cent.* In the present study, however, as a result of repeated examinations the Type III. pneumococcus was recovered from 17 per cent. of the normal persons examined, a percentage which is more in keeping with the American figures. Furthermore, it was found that once established in the nasopharynx the Type III. pneumococcus showed a greater tendency to persist than did the organisms of Types I., II., or Group IV. This is demonstrated in Table VI. in which is set forth the incidence of these organisms in 11 Type III. carriers upon whom repeated examinations were made for at least five months after the detection of the carrier state.

TABLE VI

Illustrating Degree of Persistence of Type III. Pneumococcus in 11 Normal Persons

Carriers.	Apr.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.	Jan.	Feb.	Mar.	Apr.
A ..	III.	III.	III.	..	III.	III.	III.	III.	III.	III.	..	..	..

C ..	III.	—	IV.	..	III.	III.	—	IV.	III.	III.	—	—	—
D ..	III.	—	—	..	III.	—	III.	IV.	IV.	IV.	IV.	—	—
E ..	III.	—	—	..	..	III.	III.	II.	—	IV.	—	—	..
F ..	IV.	IV.	—	IV.	III.	IV.	—	—	—	—	—	—	III.
G ..	..	..	..	III.	III.	III.	III.	—	III.	—	IV.	IV.	IV.
H ..	..	..	..	..	..	..	..	..	III.	IV.	III.	—	IV.
I ..	—	III.	..	—	—	IV.	IV.	..	..	..	..	..	..
J ..	IV.	IV.	III.	..	—	—	—	—	IV.	IV.	..	..	..
K ..	..	..	..	..	..	..	..	III.	IV.	—	IV.	..	..

The Table shows that six nurses were fairly constant carriers of the Type III. pneumococcus for periods varying from 6 to 13 months. Carrier A proved to be a true persistent carrier in as much as the organism was isolated on every examination over a period of ten months. In Carrier B the organisms showed considerable intermittency during the first seven months of the inquiry, but were constantly recovered during the last six, while in Carrier F the Type III. pneumococcus was isolated in August, a Group IV. organism in September, and no other pneumococci were recovered until April, when the Type III. organism again appeared.

Summary

A study of the epidemiological characters of acute primary pneumonia in adults showed that the highest prevalence usually occurred in the spring months. In the selected healthy community under observation it was noted that the highest incidence of Group IV. pneumococci also occurred at that time of the year. In 1932 the occurrence of lobar pneumonia in epidemic form was more marked than in the years immediately preceding and was intimately associated with the incidence of acute primary *pneumonia* in children, to such an extent that it appeared that on each occasion the prevalence of lobar pneumonia was merely an incident in a respiratory epidemic. It is possible that the occurrence of influenza in the city provoked the second outbreak of lobar pneumonia, and it might seem as if epidemic outbreaks of the disease could coincide with the usual rise in the incidence of Group IV. pneumococci in the nasopharyngeal passages of the community, or develop *suddenly by reason of some powerful exciting influence,* as in this instance by the widespread occurrence of influenza. Furthermore, it would also seem more in accordance with the epidemiological evidence that the Types I. and II. organisms develop autogenously from the parasitic Group IV. pneumococci which normally inhabit the nasopharyngeal passages.

Although the case of lobar pneumonia was demonstrated to be a fertile source for the dissemination of the Type I. or II. pneumococci to healthy persons, yet a direct spread of infection seldom occurred and the carrier state was therefore regarded as a normal and generally harmless sequel, of little *consequence from a public health standpoint.* The Group IV. pneumococci were the dominant organisms in the community, but their incidence was subject to marked degrees of fluctuation, and in gauging their significance the employment of antisera for Types IV.–XXXII. was a most valuable aid. Regarding the Type III. pneumococcus it would appear as if it were really essentially saprophytic in character. *It occurred as a persistent parasite in 17 per cent.* of the persons examined, and its incidence appeared to bear no relation either to the individual case of pneumonia or to the general prevalence of the disease.

Conclusions

(1) Acute pneumonia due to pneumococci Types I. and II. is a disease which usually has its highest prevalence in the spring of the year. (2) In periods of epidemic prevalence there is, as a rule, evidence of increased *activity* among the Group IV. pneumococci. (3) The development of Types I. and II. pneumococci is autogenous in the vast majority of cases. (4) The Types I. and II. pneumococci seldom promote the spread of the disease by direct contact. (5) When responsible for a case of acute pneumonia, however, they readily spread to persons in contact and produce the carrier state. (6) Secondary contact *carriers are infrequent.* (7) Group IV. organisms are common organisms in the community. Their incidence is not constant but subject to a marked *degree of fluctuation.* (8) *The use of Group IV.* antisera for Types IV.–XXXII. is of considerable value in determining whether any one type is more prevalent or more fatal. (9) The Type III. pneumococcus is primarily saprophytic in character and in *the present inquiry was recovered from 17 per cent.* of the normal persons examined.

I desire gratefully to thank Dr. William Dow, medical superintendent of Knightswood Hospital, who afforded me every available facility and *encouragement.*

[illegible] HOSPITAL.—Lord Wakefield [illegible] ation-stone of this new hospital [illegible] id gave a cheque for £1100 to complete the £10,200, which the building will cost. The institution, which will have 20 beds, will serve a population of 40,000. The equipment will cost a further £2000.

COMPENSATION FOR OCCUPATIONAL DISEASES

INTERNATIONAL ACTION

IN 1925 the International Labour Conference adopted a Convention providing for compensation for occupational diseases, the important proviso of which is that it shall be on the same basis as in national laws for accidents. A schedule of a few occupational diseases is a part of this Convention. The schedule is a very short one because great difficulty was experienced in arriving at agreement in regard to the basic principle of the Convention, and it was deemed wise to restrict the number of diseases inscribed on the schedule.

However, this conference passed a recommendation to the effect that its governing body should instruct the International Labour Office to continue its studies with a view to subsequent revision of the Convention by additions to the schedule. In the nine years which have elapsed since the adoption of the 1925 Convention the matter has been studied by the International Labour Office and its correspondence committee on hygiene, and the present conference had before it a proposal for a considerable extension of the schedule. In the first place the conference had to decide whether the partial revision of the Convention of 1925 was to be dealt with in toto at the present conference or whether the so-called "two reading" procedure should be followed. In this latter case, after discussing the general outline of the Convention, a questionnaire is prepared which is sent to the Member States for reply, and a final decision in regard to the Convention is taken at the following session. In this instance it would have been 1935. However, in spite of considerable opposition the conference decided to deal with the revision of the Convention in one reading.

The matter was then referred in accordance with the rules of procedure to a committee which, after sitting for over a week, recommended the extension of the schedule by the addition of the following occupational diseases:

Silicosis, with or without pulmonary tuberculosis; phosphorus poisoning; arsenic poisoning; poisoning by benzene, its homologues, and their nitro- and amido-derivatives; poisoning by the halogen derivatives of hydrocarbons of the aliphatic series; pathological manifestations due to radium, radio-active substances, and X rays; and primary epithelioma of the skin arising out of handling tar, pitch, and similar substances.

The principal difficulty in dealing with the draft Convention centred on the inscription of silicosis, and particularly on whether compensation should be paid for silicosis when tuberculosis coexists. A number of medical men, acting as expert advisers to certain national employers' associations, were on the committee, and these strongly urged the view that it is difficult to separate during life for assessment purposes the incapacity caused by silicosis from that caused by associated conditions, especially tuberculosis. It was stated that at least in Holland no tuberculosis was ever observed in association with silicosis, and on the other hand it was stated that certain forms of tuberculosis without any silicosis produced the same signs and symptoms as silicosis with tuberculosis. Various difficulties arising out of legal enactments in certain countries were also adduced in favour of providing compensation for silicosis only and not for the total incapacity arising out of silicosis with tuberculosis. Difficulties of administration in countries which allow the certification for compensation of incapacity or death by any registered practitioner were also urged against the inscription of silicosis, as it was considered—no doubt correctly—that the diagnosing of this condition can only be carried out satisfactorily by experts. However, in the end the committee adopted by a very large majority the following formula of inscription:

Silicosis with or without pulmonary tuberculosis, provided that silicosis is an essential factor in causing the resultant incapacity or death.

The revision of the Convention as proposed by the committee was adopted by the conference by 78 votes against 8.

The committee also submitted to the conference for transmission to the governing body a series of five resolutions, the first four of which referred to silicosis. These resolutions can be briefly summarised as follows:

The states ratifying this Convention are recommended:

1. To establish a list of trades and industries in which there is a risk of contracting silicosis, giving due regard to the progress of scientific and clinical investigations into the ætiology of the disease.
2. To give attention to prophylactic measures, especially to the prevention of dust and the importance of preliminary and periodical examination of employees subjected to exposure to silica dust.
3. To entrust the diagnosis and certification of silicosis to medical men specially qualified for this work with facilities for adequate radiological examination, and to organise some suitable method of coördinating experiences concerning the carrying out of medical, radiological, and pathological examinations as well as the results of scientific investigations.
4. To institute special investigations regarding the incidence of silicosis and tuberculosis in the coal-mining industry.

The fifth resolution recommends the governing body to consider the inscription on the agenda of the 1935 conference the consideration of adding to the schedule ankylostomiasis, carbon disulphide poisoning, and such other occupational diseases as may be considered advisable.

MEDICINE AND THE LAW

Charge of Criminal Abortion: Effect of Previous Acquittal

William Maxwell, a herbalist, has given his name to a leading case in English criminal law. He was convicted at York assizes last February on two counts of an indictment charging him with (1) manslaughter of a woman whom he was treating as one of his patients, and (2) using upon her an instrument with intent to procure miscarriage. He was found guilty and was sentenced to 20 months' imprisonment. In criminal cases the English law shows special anxiety that the evidence laid before a jury shall be limited to the particular issue which it has to try. Except in specified exceptional circumstances the jurors must not be told that the accused has done (or is suspected of having done) the same thing before. Such information might persuade them into thinking that on that account he is likely to have been guilty in the case before them now. The more natural it would be for jurors to be so persuaded, the more assiduously does the law seek to exclude the risk of persuasion. Maxwell had not been previously convicted of criminal abortion or of any other crime. But he was tried seven years ago at Leeds for the manslaughter of a woman patient and was acquitted. This fact was brought out, as will presently be explained, at the trial at York. What effect would it have on a jury's mind? What effect ought acquittal to have on anyone's mind? These were the issues which the recent judgment in R. *v.* Maxwell had to decide. The jury at York last February was allowed by the trial judge to hear of the previous acquittal and to convict Maxwell. The Court of Criminal Appeal refused to interfere. The case was referred to the House of Lords by a rare exercise of the Attorney-General's power to certify a point of criminal law as of exceptional public importance. The House of Lords upset the conviction and ordered Maxwell's release.

THE FACTS AND THE STATUTORY POSITION

There is no need to elaborate the facts disclosed at Maxwell's trial. It was his case that, at the time of the seizure and collapse which immediately preceded his patient's death, he was in another room; he said he had not touched her on this occasion. The Lord Chancellor observed that the evidence against Maxwell at York was undeniably strong and some very damaging admissions had been made. These considerations, of course, made it more essential to give him all proper protection from injustice. The mention of the previous trial and acquittal in 1927 "might have been the last ounce which turned the scale against him."

The cross-examination of an accused person is governed by the Criminal Evidence Act, 1898, which enabled all accused persons to be witnesses in their own behalf. They received specific protection but there were certain conditions in which the protection might be forfeited. In the application of the Act to Maxwell's case the material words are those which enact that an accused person, giving evidence as a witness, "shall not be asked . . . any question tending to show that he has committed or been convicted of or been charged with any offence other than that wherewith he is then charged, or is of bad character, *unless* . . . he has given evidence of his own good character." At York the defence seems to have almost unnecessarily drawn attention to what had happened at Leeds. A witness for the Crown was cross-examined as follows: "Is it a fact within your own knowledge that a patient whom he was treating some years ago died during the treatment?" The answer was "Yes." Counsel for the prosecution then claimed the right to clear the matter up by asking "What happened to William Maxwell upon the death of his patient?" The judge disallowed the question in that form, but eventually the point arose again when Maxwell entered the witness-box. He told his counsel that he had had large numbers of women patients. "Have you ever been convicted of any offence in your life?" "No, I have lived a good, clean, moral life." This certainly amounted to "giving evidence of his own good character" within the meaning of the Criminal Evidence Act. It would have entitled the Crown to cross-examine Maxwell about his previous convictions but Maxwell had no previous convictions. The Crown elicited from him the fact of the previous trial and acquittal at Leeds in 1927, and the case proceeded with the result already stated. The Crown could argue that, by giving evidence of his own good character, Maxwell had thrown his statutory shield away and had exposed himself to a question whether, in the words of the Act, he had "been charged" with another offence. The Crown contended that, after the questions asked by the defence had elicited half the story, it was proper that the jury should hear the whole story.

LORD SANKEY ON THE EFFECT OF ACQUITTALS

The House of Lords answered these arguments by declaring that an acquittal nullifies a charge. Nobody would ever be able to clear his character if the fact that a prima facie charge had once been made against him were always to endure as a slur upon his reputation. The prosecution must not say that a man who has been acquitted can still remain under a cloud. If someone is charged before a magistrate and the prosecutor immediately admits that he has made a mistake, there is no slur; such an idea was "contrary to the whole idea of English jurisprudence." The mere fact of a charge "cannot in general be evidence of bad character or be regarded as other than a misfortune." The acquittal at Leeds in 1927 did not go to show that Maxwell must be guilty at York in 1934, or that Maxwell was an untrustworthy witness; it was therefore a quite irrelevant fact. Apart from the Criminal Evidence Act, irrelevant matters must be excluded because, if allowed, they were likely to lead the minds of the jury astray into false issues. Lord Sankey's judgment in R. *v.* Maxwell is a reminder that legal standards of probability are different from ordinary standards. The ordinary man, if selecting a confidential clerk or a domestic servant from a group of candidates, would probably avoid choosing one who had been previously convicted of dishonesty or who had even been suspected of dishonesty. In a court of law this consideration or prejudice must be rigidly excluded.

VITAMIN STANDARDISATION

SECOND INTERNATIONAL CONFERENCE

THIS conference, convened by the Health Section of the League of Nations, met on June 12th at the London School of Hygiene and Tropical Medicine. The personnel was almost the same as on the first conference in 1931, including Profs. Steenbock, von Euler, Poulssen, Jansen, Fridericia and Drummond, and Madame Randoin; new faces were those of Prof. Szent-Györgyi from Hungary, Dr. Nelson from U.S.A., and Prof. de Mattei from Italy. The absence of the German delegates was much regretted. The conference met under the chairmanship of Dr. E. Mellanby, F.R.S., and Miss Harriette Chick, D.Sc., and Dr. W. R. Aykroyd were, as before, the secretaries.

Sir GEORGE BUCHANAN, as a member of the Permanent Standards Commission, opened the conference and Sir HENRY DALE, F.R.S., representing the same body, followed with some words of general advice, applicable to all biological standards as well as to vitamins. He urged the conference to confine its official deliberations to the definition of standards and units and to avoid discussing methods of biological testing, which were the concern of the individual worker and did not demand international coöperation. Finally he begged the delegates, when they left the conference to return home, to give their fullest consideration to the actual means of implementing the decisions which they had just taken, for there existed no international machinery for imposing the use of the standards and units upon the governments, scientific workers, or industrial concerns of the various countries. Sir Henry Dale made the suggestion, in this connexion, that all those possessing editorial influence with any journal should bring pressure to bear on the editorial boards to refuse papers dealing with vitamins in which units other than international units are used.

The conference spent a part of its three days' life in plenary session, but for the larger part of the time it was broken up into four committees, each dealing with one of the vitamins A, C, D, and B_1, for which standards and units had already been set up in 1931. The work of the delegates was to consider how the standards and units which they had then established had worked in practice, and what changes ought to be made in response to the very considerable body of knowledge which had accumulated in the intervening three years. The reports on the working of the standards revealed few complaints, the only important one being connected with the use of crystalline carotene as the standard for vitamin A; workers complained that it offered difficulties in the actual mechanical handling. The advance of knowledge, however, revealed a number of points at which improvement might be made. Three of the vitamins, A, C, and D, had progressed into being more or less well-defined crystalline bodies, and the day was even dimly in sight where a biological test might be abandoned altogether, and a measurement of a chemical reaction or of a physical constant might take its place.

The actual decisions of the conference are best considered under the heads of the individual vitamins. The recommendations are embodied in a report which awaits the confirmation of the Permanent Commission on Biological Standardisation. The Permanent Commission meets later in the summer, and after its meeting the report will be published.

Vitamin A.—Knowledge of the chemistry of carotene has so progressed that pure β-carotene, of m.p. 184° C. (corr.) and optically inactive, was able to be recommended in place of the impure carotene, provisionally adopted before. The unit previously adopted was the biological activity of 1 γ of the standard carotene: β-carotene possesses greater biological activity than the old standard, and the amount of β-carotene which would provide a unit of the same size, that is to say, which possesses the same biological activity as 1 γ of the old standard, was fixed at 0·6 γ. Much work has been put into ascertaining a suitable solvent for administering the carotene to rats: in coconut oil, fulfilling certain tests, so satisfactory a solvent has been found that it was possible to recommend the distribution of the new β-carotene standard in solution, thereby obviating the difficulties encountered by workers in handling the crystalline material. A well-tried sample of cod-liver oil, whose potency in international units has been well established, was recommended for adoption as a subsidiary standard. Finally, a spectrophotometric test, measuring the coefficient of absorption at 328 mμ, was regarded in certain strictly defined circumstances as being a satisfactory measurement for vitamin A in liver oils and concentrates. A figure is given relating this measurement to the biological activity and thus, within a narrow sphere, the use of a biological test is eliminated.

Vitamin B_1.—The adsorbate on acid clay, previously adopted, has been found most satisfactory in practice; its further adoption was therefore recommended, together with the maintenance of the unit as then defined.

Vitamin C, like vitamin A, has progressed into the realm of pure substances: the lemon juice previously adopted as standard was therefore abandoned and pure *l*-ascorbic acid, as defined by a number of physical constants, was recommended in its stead. The unit was retained and 0·05 mg. of *l*-ascorbic acid was accepted as the equivalent in biological potency of 0·1 c.cm. of fresh lemon juice, whose biological activity was previously used as the unit.

Vitamin D.—The old standard material of irradiated ergosterol in olive oil solution was considered by all to have behaved well and there is still a large quantity of it available. It was not considered that there was any advantage to be gained at present by attempting to substitute crystalline vitamin D for it, but provision was made for such an ultimate change, when it should appear desirable. One very awkward set of facts, however, came to light in considering the standard for vitamin D. Research has recently been accumulating results which indicate that all animals do not utilise all antirachitic materials in the same relative proportion. Cod-liver oil, for instance, is much more potent as an antirachitic, relative to irradiated ergosterol, when it is tested on chicks than it is when tested on rats. Thus if a biological test of cod-liver oil as compared with the international standard irradiated ergosterol is made with chicks as the test animal, a much larger number of units of vitamin D will be attributed to the cod-liver oil than would be the case if the same comparison were made with rats. It is possible that other animals, pigs and man, are again different, and it is impossible, in the present imperfect state of knowledge, to avoid the major heresy in biological standardisation of defining the animal used for the test. Though it proved impracticable to obviate this difficulty completely, there is little doubt that further research will once more make generalisation possible.

Other vitamins.—The possibility of setting up pure lactoflavine as a standard for vitamin B_2 was canvassed, but it was generally felt that it would be premature to do so and that there were no practical arguments for haste, since deficiency of vitamin B_2 was not yet definitely linked up with any recognised syndrome of disease in man.

The conference was evidently a triumph of international coöperation; it created an atmosphere where only true facts could survive and where no element of individual or national self-interest crept in to mask the truth. In those circumstances an agreed set of recommendations was easily produced in the brief space of three days.

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

DISCUSSIONS ON HEALTH INSURANCE

IN spite of official opposition on the part of the American Medical Association to any form of national health insurance, a certain ferment of inquiry is at work in many parts of the country. Less than a year ago (July 12th, 1933) a committee on survey of medical services and health agencies reported to the House of Delegates of the Michigan State Medical Society recommending the adoption of the principle of health insurance. The House of Delegates was not ready to accept this recommendation, but in January last sent Dr. Henry A. Luce, speaker of the House, and Dr. Nathan Sinai, chairman of the committee, to England to make a further study of the English system. These observers have made their report and the Michigan doctors are now committed to the principle of health insurance provided that its administration is under the control of the medical profession. A detailed plan will be submitted to the House of Delegates when it reassembles in the autumn. It is probable that this plan will provide for an administrative board of governors made up of three physicians, one dentist, one pharmacist, one nurse, one hospital superintendent, two representatives of industry, and two representatives of the general public. The politicians are not invited to participate. Fear of corruption through political control has been one of the main forces operating against health insurance in this country. The voluntarily insured family will be guaranteed free choice of physician.

In the meantime the West Coast has provided many private experiments in health insurance, some respectable, others not. In the State of Washington a large proportion of the medical profession is engaged in organised contract practice, and there is a feeling that a system of compulsory health insurance will be the outcome of the present trend. In California the majority of the profession is opposed to health insurance, but there is an important minority with many lay sympathisers. At the 1934 meeting of the California State Medical Association a State-wide plan for providing hospital service in return for periodic payments failed to secure a necessary two-thirds majority. Dr. Rodney, spokesman for the opposition, is an ardent advocate of compulsory health insurance. It was, as you have already noted,[1] in the lively atmosphere of California that Mr. John Kingsbury, co-author with Sir Arthur Newsholme of "Red Medicine," and director of the Milbank Memorial Fund, recently launched his proposal for meeting the present problem of the costs of medical care.

The basic problem, says Mr. Kingsbury, is this: the costs of medical care are incurred in a haphazard, uncertain, and unbudgetable way. And the underlying cause is the fee-for-service purchase of medical service. He agrees with Sir Arthur Newsholme that the health of every individual is a social concern and responsibility, and that medical care in its widest sense for every individual is an essential condition of maximum efficiency and happiness in a civilised community. After discussing the history of insurance in Europe and in America Mr. Kingsbury comes to "tentative conclusions" based upon the incomplete report of Dr. I. S. Falk and Mr. Edgar Sydenstricker and upon his own studies. An insurance plan should not aim primarily to furnish financial assistance to the poor, but to enable all who cannot afford to pay for adequate medical service as individuals to purchase it as groups. The plan should therefore care for all who have incomes up to $3000 or even $5000. However, the plan must include the very poor who are slow to come into a voluntary system. Insurance should therefore be compulsory. European experience shows clearly that schemes which are voluntary at first eventually become compulsory. Cash benefits should not be included in a health insurance scheme. The cost of adequate service is estimated at $36 per person annually. This includes specialist and nursing care, dental care, in-patient treatment when needed, drugs, and medicine; also institutional care for mental disease and tuberculosis. Medical services of the kinds which are ordinarily purchased privately would cost about $27 per person. Administrative control is given to the laity for financial and executive problems, and to the profession for control of professional problems. Mr. Kingsbury holds that European systems of insurance have never dealt adequately with preventive care. Provision in his scheme is made for periodic medical examinations, immunisations, prenatal and postnatal care. The present is a favourable opportunity for the consideration of all these matters in California, as the State Senate have just appointed a committee to investigate the high costs of sickness.

IRELAND

(FROM OUR OWN CORRESPONDENT)

THE IRISH MEDICAL ASSOCIATION

THE annual meeting of the Irish Medical Association was held in the Royal College of Surgeons, Dublin, on June 26th, under the presidency of Dr. Robert J. Rowlette. For the first time in its history the programme of the meeting included a scientific session. Two discussions had been arranged—on the modern treatment of pulmonary tuberculosis, and the relations of the medical officer of health and the general profession. Dr. E. T. Freeman gave a careful account of the gold treatment of pulmonary tuberculosis and of the parts that the various surgical procedures—artificial pneumothorax, phrenicectomy, thoracoplasty—play in treatment. He was followed by Dr. J. T. Daniel, tuberculosis officer of the city of Dublin, who gave a survey of the present-day lines of treatment, without confining himself to the newer methods. He stressed the important place in treatment that must be taken by rest, fresh air, diet, and hygienic surroundings and habits of life. Others who took part in the discussion were Dr. John Shanley, Dr. J. C. Flood, Dr. A. J. d'Abreu, and the president. Dr. J. A. Harbison, medical officer of health for County Dublin, opened the second discussion, and surveyed the respective spheres of action of the medical officers of health and the general practitioners. He was followed by two other county medical officers of health, Dr. J. A. Musgrave, of Louth, and Dr. T. J. R. Maguire, of Roscommon, and by Dr. T. P. McDonnell and Dr. T. F. Armstrong, who spoke from the point of view of the general practitioner.

In the afternoon the business session of the Association was held. Dr. Rowlette and Mr. H. F. MacAuley were declared re-elected as president and vice-president respectively, and the names of those elected to the council were read out. The annual report states that the membership during the year 1933 had increased from 339 to 365. Six members had died, 14 had resigned, and 27 had been removed from the list for non-payment of subscriptions; 73 new members had been elected. During the year a joint council with the Irish committee of the British Medical Committee had been formed—the General Council of Medical Associations—and this body was authorised by the Irish Medical Committee to act for the profession as its executive in representations to Government departments. The finances of the Association were satisfactory. Dr. Thomas Gillman Moorhead was elected an honorary member of the Association.

An account of conversations between the B.M.A. and the Irish Medical Association with a view to amalgamation as far as members resident in the Irish Free State were concerned was given by Mr. MacAuley, vice-president. The meeting expressed its approval of the steps that had been taken and authorised the continuance of conversations on the same lines.

In the evening the members dined together and entertained a number of guests at the Dolphin Hotel. No annual dinner had been held since 1914. The guests included Mr. Sean T. O'Kelly, vice-president of the Executive Council of the Irish Free State and Minister for Local Government and Public Health; the Lord Mayor of Dublin; the Attorney-General; Dr. Moorhead, president of the B.M.A.; and Mr. Doran, chairman of the Irish Hospitals Commission.

KING'S PROFESSOR OF THE PRACTICE OF MEDICINE

The President and Fellows of the Royal College of Physicians of Ireland have elected Dr. Victor Millington Synge to the King's professorship of the practice of medicine in the School of Physic in Ireland, Trinity College, Dublin, vacant by the death of Dr. F. C. Purser. Dr. Synge has been for several years one of the visiting physicians to the Royal City of Dublin Hospital. It will be remembered that Dr. Purser had only held the office two months when his sudden death occurred.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

WORK FOR THE DEAF AND BLIND

The Scottish Association for the Deaf have opened a boot-repairing factory in Glasgow, which is the first of its kind in Scotland. The factory is equipped with modern plant, and an instructor foreman has been appointed. There is accommodation for about 24 workers, most of whom will be deaf. Sir Robert Wilson, chairman of the association, in opening the factory, spoke of the difficulty in obtaining positions for the deaf when they left school, as employers feared that their handicap might increase the number of accidents. Dr. James Kerr Love, vice-president, said that during the last 40 years the percentage of acquired deafness among school-children had been reduced by half, which he attributed to better attention in hospitals and the work that was being done among school-children. He believed that at present the powers of the local authorities were not being fully used.

At the recent Aberdeen conference the capacity of the blind to learn salesmanship was discussed. It was admitted that though successful selling schemes for disposing of the work of the blind have been organised by all the societies of Scotland, most of the centres could give instances of blind people who had failed to earn their own living as salesmen. It was thought this was probably due to lack of enterprise and proper training. Modern business methods should be made available to the blind by means of braille price tabs and receipt slips and so forth. In spite of differences of opinion as to how far it was practicable to teach the blind salesmanship it was felt that the idea should be systematically tried. The blind tea-merchant has long been a familiar figure in Scotland, and though the sale of other merchandise —notably their own handiwork—is more complicated, a strong interest in the possibilities of this type of work for the blind was shown at the conference.

SHEFFIELD RADIUM CENTRE

DEPARTMENT FOR DEEP X RAY THERAPY

This department, which has been in use for some months, was to have been opened by the Duke of York on July 5th, but the engagement had to be cancelled on his doctors' orders. The apparatus for high voltage X ray therapy has been especially designed and incorporates the latest advances. It is, moreover, so designed that if the X ray tube suffers from a broken or worn out filament, or if the anode requires adjustment, the tube can be taken to pieces and put together again with little trouble and at very small cost, and routine work can be resumed within an hour or two. The Greinacher high tension circuit has one end earthed and supplies two tubes at 200 kv. and 10 m.a. each. The current is rectified by continuously evacuated valves and then smoothed by condensers. The group of research workers of Metropolitan Vickers, the makers of the apparatus, described its advantages in the February issue of the *British Journal of Radiology.*

The necessary vacuum in both the X ray tubes and the continuously evacuated rectifiers is maintained by means of oil diffusion pumps, in action during all the time when the apparatus is in use, and the tube is sealed by the apposition of surfaces ground optically flat to within one or two wave-lengths of light. The anticathode in each tube is hollow and the surface emitting X rays is of gold. Inside the hollow anticathode water is circulated from the mains for cooling.

From the medical point of view we understand that the apparatus has so far been very satisfactory. The movements of the tube are similar to the well-known Holfelder Cannon. The whole tubes can move bodily up or down and the X ray beam can be used in any direction with the exception of an angle of 30 degrees which is blind because the water-cooling tubes cross the path of the beam. One tube has already been used for some 2000 hours and the routine work has been in progress all the time with only a few minor interruptions. The actual time of emission of X rays has been about 1000 hours. The number of patients treated (mostly by fractionation techniques) was 160 by the end of January—i.e., after three months' work. In addition, many hours have been spent in making physical measurements.

The apparatus is controlled by a staff nurse with no previous radiological training and all fields are arranged by a medical officer.

BRITISH HEALTH RESORTS ASSOCIATION

NORFOLK COAST CONFERENCE

The conference which took place on June 30th was the first to be held on the East coast.

Dr. Burton-Fanning (Norwich) presided at the morning session at Sheringham, and a summary of the aims and objects of the association was given by its founder, Lieut.-Colonel R. H. Elliot.

Dr. R. A. Young (London) then opened a discussion on

THE SEASIDE RESORT IN THE TREATMENT OF RESPIRATORY DISEASES

by quoting the words of Dr. Ellsworth Huntington (U.S.A.): "The climate found on the shores of the North Sea is the best in the world for human health and activity." Great Britain, Dr. Young continued, offered health resorts suitable, if chosen with discretion, for practically all the ills to which her islanders were subject. It was essential, however, if we were to make the best of our resources, that the indications and contra-indications of each resort and any seasonal limitations it might have should be better understood; nor must the effect of environment be ignored.

The coast and hinterland of Norfolk was rich in all the factors, climatic and environmental, that tend to stimulate, and its effect in those cases of respiratory disease which were capable of reaction to stimulating influences was almost magical.

Dr. L. S. T. Burrell (London) stressed the importance of putting the individuality of the patient even before the nature of his malady in selecting the health resort. The factor of peculiar value from the point of view of health in the English climate was its variability. Only in rare cases—where the mental make-up of the patient was such as to be impressed by foreign surroundings—had he ever known greater improvement to occur abroad than at one of the health resorts at home.

Dr. Andrew Morland (Mundesley Sanatorium) said that the dryness and freedom from fog of the East coast, together with the absence of extremes of summer heat or winter cold, made it an ideal all-the-year-round resort for the convalescent from acute respiratory disease. For those whose nutritive powers were inefficient some protection was necessary during the colder winter months. For this and other reasons he advocated sanatorium treatment for the consumptive. Though in its stimulating character the climate of the coast was comparable with that in the Alps, it had not the disadvantage of increasing depth and rate of respiration and of pulse-rate that were sometimes associated with high altitudes. Moreover, the important question of diet was much more satisfactorily arranged at home where plenty of fresh milk and vegetables were available. There was a certain robust type of consumptive, capable of rapid reaction, whose progress could be expedited by wintering in Switzerland, but the large majority made just as good if not better progress at sanatoria at home. Dr. Morland illustrated his thesis by graphs, one showing that the mortality rate from phthisis was appreciably less in countries bordering on the North Sea than elsewhere on the continent, and another that the gain in weight showed less seasonable variation in England than abroad. As regards seekers after health in general, Dr. Morland considered that one of the chief factors inducing people to go abroad was the irritating restrictions of D.O.R.A. at home resorts.

Dr. Valentine Blake (Great Yarmouth), president of the Norfolk and Norwich Medico-Chirurgical Society, presided at the afternoon session held at Cromer.

Climatic Factors in Treatment

Dr. Fortescue Fox (London) opened a discussion on "Climatic and allied factors in the incidence and treatment of disease, with special reference to the coast of East Anglia." He said that the invigorating climate of the coast, due to a remarkable combination of warm sunshine and cool air-currents, was in his opinion a great national asset. Too little attention had been paid in the past to the study of climate, and he pleaded for systematised observation and the collection of data by medical men practising in the coastal resorts, so that the matter could be placed on a more scientific basis.

Dr. S. H. Long (Norwich) referred to the Norfolk and Norwich Hospital's convalescent home at Cromer, and said that over a period of 25 years the rapidity and degree of improvement of the patients sent to the coast had been remarkable; the home was in constant use except for a period of six weeks in the winter.

Dr. W. J. Pearson (London) also stressed the immediate nature of the response shown by the debilitated to the tonic effects of the Norfolk climate. While it was true that in adults certain diseases either in themselves called for sedative treatment or resulted in so much pathological change as to render their victims incapable of reaction, this was rarely if ever the case in children. It followed that if the coast was too stimulating for adults in some circumstances, for children no better climate could be found.

Mr. L. C. W. Bonacina, F.R.Met.S., said there was a great deal of public misconception about the coast, particularly as regards its winter climate, owing to the false association of East coast with East winds. The Norfolk coast got no larger share of East winds than the country generally, for they blew with equal frequency elsewhere; neither was the direction of the wind the deciding factor in its pleasantness or the reverse. The temperature of a wind approaching England from the continent of Europe might be raised ten degrees by its passage across the Channel or the North Sea. On the contrary, a south-west wind reaching the East coast across a snowclad England might be distinctly colder. Taking the year round, wind, sunshine and vapour-pressure—the climatic factors that mattered most for health—were ideally blended on the coast of Norfolk.

Among the other speakers in the morning or afternoon were Sir Holburt Waring, Prof. Langdon Brown, Sir Stanley Woodwark, Drs. Leonard Findlay, Howard Humphris, M. B. Ray and J. B. Alexander, of London, and a number of Norfolk practitioners. The discussions were remarkable for their frankness and unanimity, especially regarding the contra-indications of the coast. As might be expected, these are illnesses of a type which at home would be treated on sedative lines, such as borderline mental cases, asthmatics of the type in whom the predominant factor is probably nervous, sufferers from migraine and epilepsy, those with hyperarterial tension, and elderly bronchitics with cardiac failure.

The members of the conference were received by the vice-chairman of the Cromer Urban District Council on the evening of their arrival, and entertained at dinner on Saturday evening, when Lord Meston was the principal guest. They were also entertained by the Sheringham Urban District Council to luncheon on Saturday, while Sunday was devoted to motor excursions along the coast.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Rear Admiral R. W. B. Hall, C.B., O.B.E., has taken up his duties as Director-General of the Medical Department of the Navy in succession to Sir Reginald St. G. S. Bond, K.C.B.

The following appointments have been notified:—

Surg. Comdr. A. W. Gunn to *Sussex* on recommg.

Surg. Lts. J. G. Slimon to *Vernon*; D. D. Steele-Perkins to *Gnat*; A. D. Hepburn to *Victory*, for R.N.B.; S. H. R. Price to *Victory* for R.N.B., Portsmouth, and to Exeter; H. E. B. Curjel to *Drake* for R.N.B., Devonport; H. A. Clarke to *Victory* for R.N.B., Portsmouth; and F. H. Ward to *Sussex* on recommg.

Surg. Lt. (Short Service) C. D. D. de Labilliere transferred to Permanent List.

ROYAL ARMY MEDICAL CORPS.

Capt. D. K. Weston relinquishes his commn.

Short service commission.—The undermentioned to be Lts. on Prob.: W. M. E. Anderson, H. B. Wright, J. Boyle, R. H. Foster, J. S. Ruddell, A. G. D. Whyte (from R.A.M.C., T.A., Supern, for serv. with the O.T.C.), A. L. Pennefather, C. G. O'Driscoll, D. T. Swift, F. E. Buckland, A. MacLennan, J. H. J. Crosse, J. Morgan, R. A. Stephen, E. H. P. Lassen, R. S. Vine, I. Buchanan, J. E. Jameson, M. W. Allen, W. T. Bermingham, and K. H. Clark.

The undermentioned Lts. on prob. are secd.: A. G. D. Whyte, C. G. O'Driscoll, A. MacLennan, J. Morgan, R. A. Stephen, K. H. Clark, and M. J. Horgan.

ARMY RESERVE OF OFFICERS

C. M. Fraser to be Lt.

TERRITORIAL ARMY

Capt. A. H. G. Down resigns his commn.

Lts. L. F. Richmond and N. H. Leslie to be Capts.

D. S. Anderson (late Offr. Cadet, St. Andrews Univ. Contgt., Sen. Div., O.T.C.) and A. D. Forgie to be Lts.

The King has conferred the Efficiency Decoration upon Maj. R. J. Bruce.

TERRITORIAL ARMY RESERVE OF OFFICERS

Lt.-Col. and Bt.-Col. J. W. Keay, Lt.-Col. J. H. Stephen and Maj. J. A. Morris, having attained the age limit retire and retain their rank, with permission to wear the prescribed uniform.

INDIAN MEDICAL SERVICE

Majs. to be Lt.-Cols.: B. Z. Shah, V. R. Mirajkar, A. J. D'Souza, B. C. Ashton, M. M. Khan, E. R. Daboo, and B. G. Mallya.

Capts. to be Majs.: F. R. W. K. Allen, M. Taylor, and W. Lawie.

Temp Lts. to be temp Capts.: S. S. Ahluwalia, M. Singh, and P. Papatla.

It is announced that Surgeon Rear-Admiral R. W. B. Hall and Surgeon Rear-Admiral W. W. Keir have been appointed Honorary Physician and Honorary Surgeon respectively to the King.

PANEL AND CONTRACT PRACTICE

AN OPENING FOR INJUSTICE

CONSIDERING how easy it is for a patient, or relative of a patient, to bring a charge against an insurance practitioner—involving, perhaps, professional honour, or even veracity—the exact means by which justice is administered are of no little importance.

It is obviously fair and right that any adult patient should be able to send a complaint to the clerk of the insurance committee (which is responsible for the administration of medical benefit) if he thinks that his doctor has done something he ought not to have done, or left undone something that he ought to have done. The procedure in this case is for the clerk to forward relevant extracts from the letter of complaint, or possibly the whole letter, to the practitioner concerned and to ask for his observations. These observations, or extracts from them, are sent to the insured person, whose further comment is invited. If this in turn contains anything which is thought to be important for the practitioner to know it is forwarded to him. The whole correspondence, verbatim, is then circulated to the members of the medical service subcommittee. (This consists of an equal number of lay persons who represent approved societies or insured persons and of medical men who represent the panel committee and the local medical committee—which in these days often have the same personnel. There is an independent chairman usually appointed from the neutral members of the insurance committee—i.e., from those representing the county council or the Ministry of Health.) The medical service subcommittee decides whether a hearing is necessary and, if so, arranges the time and place. Finally, having heard the case, it decides whether there has been a breach of the regulations; whether, if so, there should be a caution or censure; and whether money ought to be withheld from the practitioner's remuneration, and, if so, how much. Its decision is usually confirmed by the full insurance committee, but must also be confirmed by the Ministry of Health. Either party can appeal to the Ministry when the case is reheard de novo.

There is little to complain of in this procedure, for the members of the committee are not likely to know anything about the complainant or the doctor personally and justice can be correspondingly impartial.

It sometimes happens that the insured person does not want to make a complaint, but a relative does. If on the correspondence it appears to the medical service subcommittee that the complaint is one that ought to be investigated in spite of the insured person's refusal to complain, they have the power to advise either the medical benefit subcommittee or the main committee that this is a matter which requires investigation. Thereupon a resolution is passed by one of these committees "that the matter be referred to the medical service subcommittee for investigation." This procedure is called "getting a reference." The insurance committee (or its medical benefit subcommittee) is becoming the complainant, before one of its own statutory subcommittees, against a particular practitioner.

In these circumstances it may easily happen that some of the lay members of the medical service subcommittee—those representing either insured persons or approved societies—were present at the meeting at which the reference was passed. This hardly appears fair from the point of view of administration of justice, for a complainant can hardly act with equity as accuser and judge. On the other hand, the practitioner may rely upon the support of his professional brothers, for these are not likely to have been involved in getting the reference. The position is reversed, however, under Article 32 (2) of the Medical Benefit Consolidation Regulations, 1928, which not only gives a panel committee power to send a case to the insurance committee for investigation, but also provides that the insurance committee must in this case investigate. The only tribunal for this investigation is the medical service subcommittee, and this includes several members of the panel committee, all of whom have been steeped in the details which have resulted in the panel committee deciding for a reference. What confidence will the practitioner have in the impartiality of his tribunal when his professional brothers on it belong to the body which has instituted the proceedings against him; and what hope is there of the laymen on that tribunal supporting him against the advice (as he will think) of their professional colleagues—who now represent his accusers?

The particulars of a recent case have been published for all and sundry to know. Dr. A. made a complaint to the London panel committee that Dr. B. had tried to secure the transfer of insured persons to his list. The case was heard in the usual way by the attendance of both doctors before the ethical subcommittee, where Dr. A. submitted six signed statements from patients all alleging persuasion by Dr. B. to join his panel. Dr. B. tried to refute the allegations, but there was no opportunity of examining the people who wrote the letters, since they were not present. At the subcommittee meeting, nevertheless, the allegation was held to be proved. The subcommittee took a serious view of the case and decided to ask the full panel committee to take proceedings under clause 44 of the Medical Benefit Regulations, whereby they are empowered to make representations to the Minister that the continuance on the medical list of the practitioner would be prejudicial to the efficiency of the service. When this request came before the full committee it was said quite plainly that if the case was one of canvassing the General Medical Council should deal with it. If it was only a question of removal from the panel then the proper action was to refer it to the medical service subcommittee. The point here is that there was so much discussion of the case that no one present could fail to be impressed with the opinion of Dr. B. which had been formed by the subcommittee.

Solicitors were instructed to take steps to carry out the committee's resolution and to begin proceedings with a view to the removal of the practitioner's name from the medical list. The solicitors, however, at once realised the difficulty and reported their opinion that unless the committee got further and stronger evidence their case would be unsuccessful. The subcommittee thereupon instructed them to proceed with the collection of further evidence. The solicitors did so; and their comments on the statements obtained from six witnesses were as follows: (A) and (B) were vague and would not stand up to the cross-examination. (C) Actually asked to be transferred. (D) A good witness, but would not have written had he known that there would have been any trouble; therefore doubtful strength. (E) Doctor against whom complaint was made was specially sent for and there was no mistake.

(F) This patient was told the doctor he wanted to see was Dr. A. In view of this report the subcommittee decided *not* to try to get Dr. B. removed from the panel; but as in the course of the investigations it had been discovered that he gave some of these insured persons who are not on his list medicine by prescription on the official form and on one occasion a certificate without seeing the patient, it asked the panel committee to refer the case to the medical service subcommittee for investigation. This will require the consent of the Minister of Health, for it is technically out of time owing to the delay involved in the investigation by the panel committee. The panel committee passed the reference, so that, subject to the Minister's consent, it now goes to the insurance committee. If the Minister does give consent then three of the seven men who will have to hear this case will have been familiar with the details of the complaint from its commencement, and if they are the normal medical members of that subcommittee one of them was actually present at the original inquiry whilst another in his capacity of chairman of the main committee cannot fail to have all the details of the case at his fingers' ends.

There is obviously something wrong in the administration of justice to insurance practitioners as instanced in this case. The decision of the ethical subcommittee that this man was guilty of canvassing, for which the panel committee must accept full responsibility, was based on evidence which was proved insufficient. The panel committee's decision to make representations to the Minister with a view to the withdrawal of the practitioner's name from the medical list, had therefore to be rescinded. Instead of then letting the matter drop, the panel committee decided to put this doctor on trial again on a minor charge before a tribunal in which its own members have to adjudicate and decide the penalty, if any.

The function of the panel committee (through its ethical subcommittee) should be to try and effect a friendly settlement between two doctors who are in dispute. When evidence is given that something quite serious has occurred the matter should be referred, without details being published, to the proper tribunal for the hearing of such cases, either the General Medical Council or the Ministry of Health or the medical service subcommittee. No officers of the committee (since they are ex-officio members of all subcommittees), and no members of the ethical committee should be eligible to sit as medical members of the medical service subcommittee. The ethical subcommittee has no statutory power to call evidence, it cannot pay the out-of-pocket expenses of witnesses, and by its size also it is quite unsuitable to deal with this sort of case. It appears to have been overlooked in the regulations under which the panel committee can refer cases to the medical service subcommittee for trial that its own members sit upon that subcommittee and may have taken part (as in the present case) in adjudicating upon the case previously. This seems to be a more glaring anomaly than the former method of reference by the insurance committee to its own subcommittee.

One way of getting over the reference difficulty would be to send the case to another medical service subcommittee, where, of course, no one would have had any previous details that might possibly prejudice their minds. It is clear that under the present procedure the administration of justice to an insurance practitioner may not be conducted in the proper atmosphere of impartiality.

CORRESPONDENCE

BRITISH HEALTH RESORTS ASSOCIATION

To the Editor of THE LANCET

SIR,—We have been much encouraged of late by the increasing interest shown in the work of the British Health Resorts Association by the medical profession. Our association is largely medical, not only in personnel but in its objects, which are to awaken and sustain interest in the health side of our British resorts. At our recent conferences at Harrogate and Cromer we were supported by leaders of the profession, and I venture to think that the quality of the discussions was something of which we may be proud.

Though we look in the main for financial support to the local authorities of the places we are trying to help, we are very anxious to secure more of it from the medical profession, particularly from those members practising in the health resorts or who take a special interest in climatology, balneology, and physical medicine. The recent action of the Harrogate Medical Society and the Torquay division of the B.M.A. has therefore given our council great pleasure. These bodies have circularised their members with a view to enlisting their interest in our work, and by this means we have secured a considerable number of new members. Our medical advisory committee would be glad to have an opportunity in your columns of bringing these examples to the notice of similar bodies, in the hope that they may do likewise.

Our subscription is £1 1s. a year, though we would welcome any donations, small or large. We cannot offer any direct material advantage to subscribers, but we believe there are many who would be willing to show a practical interest in a movement which has a distinctly medical as well as a patriotic aim. I shall be glad to answer any inquiries.

I am, Sir, yours faithfully,

ALFRED COX,
General Secretary.

199, Piccadilly, W., July 2nd.

JOINT LUBRICATION

To the Editor of THE LANCET

SIR,—In your last issue Dr. Shirley Jones has called attention to the importance of the viscosity of synovial fluid in relation to joint lubrication, and has inferred that certain forms of arthritis may be due to alterations in the mucin content of this fluid. Very little is known about the physiology of the mucoproteins, but it does seem fairly clear that the thyroid gland is concerned. Thus in myxœdema there is a generalised accumulation in the tissues of a colloid which is, or closely resembles, a mucoprotein, and it is also known that the secretion of the parotid gland in this disease assumes an abnormally mucoid character. Since this plethora of mucoprotein is readily corrected by thyroxine it might be anticipated that the opposite condition of hyperthyroidism would be accompanied by a paucity of mucin in the tissues, and if the synovial fluids share in these general changes, then arthritis, from defective lubrication, should be commonly encountered in Graves's disease. It is rather suggestive that S. Duncan (Jour. Amer. Med. Assoc., 1932, xcix, 1239) and others regard polyarthritis as a common complication of this disease. My argument is somewhat weakened by the fact that joint troubles are not uncommon in myxœdema. However, cartilage is very prone to undergo mucoid degeneration and perhaps the arthopathy of myxœdema may be due to degenerative softening of articular cartilage.

I am well aware of the perils of drawing conclusions from circumstantial evidence, and I am not rash enough to suggest that the thyroid plays more than a small part in the pathogenesis of arthritis as a whole. But it seems to me that direct measurements of the effect of thyroxine on the viscosity and mucin content of synovial fluid might yield useful information. I am, Sir, yours faithfully,

F. B. BYROM.

London Hospital, July 3rd.

HOOKWORM IN GOLD-MINES

To the Editor of THE LANCET

SIR,—In the current issue of THE LANCET there is a leader on Hookworm in Gold-mines, based on a paper by J. H. Hodgman, to which I am, somewhat reluctantly, bound to refer.

I have been intimately concerned with the hookworm problem on the mines referred to, and have no knowledge of a "J. H. Hodgman" ever taking an important part in this work. Presumably, therefore, he writes from second-hand knowledge, and, like most knowledge so acquired, his information is decidedly inaccurate. Within the scope of a letter it is impossible to deal with the matter fully, and I will therefore draw attention only to outstanding errors:—

(1) In 20 years' work on the gold-mines I have never seen cockroaches in any notable numbers underground.

(2) Although it was suggested that viable ova may pass through rats, repeated experiments with rats caught underground failed to confirm the suggestion.

(3) It is true that about 40 per cent. of *East Coast* natives arrive on the mines infected with hookworms, but these constitute less than *one-third* of the present labour force. Among [illegible] thirds infection is rare.

(4) The infection rate *decreases* with residence on the mines, although no mass treatment is undertaken.

(5) It is the grossest possible exaggeration to describe the latrine conditions as appalling. I say this on the ground of personal knowledge which is as wide and intimate as anyone's could be.

I am, Sir, yours faithfully,

A. J. ORENSTEIN,
Chief Medical Officer, Central Mining; Rand Mines.

Weymouth-street, W., June 30th.

LECTURES AND PAMPHLETS ON MENTAL HYGIENE

To the Editor of THE LANCET

SIR,—I have just finished reading the challenging article of Dr. Edward Mapother in your issue of May 26th, and am astounded at his concluding sentence.

> As to the giving of collective counsel upon details of mental hygiene directly to the public by lectures and pamphlets (as opposed to urging resort to expert advice), in view of all the possibilities of misunderstanding and misapplication, it seems to me likely that on the whole this will do more harm than good.

Earlier in the lecture Dr. Mapother writes (regarding sex experience and sex education):

> "The first general prophylactics needed are the steady growth of a morality that is rational rather than traditional, honesty among adults, and proper education of the child."

If lectures and pamphlets do more harm than good how does he propose to apply, for example, the above excellent prophylactics? Does he condemn all pamphlets? Specifically, would he condemn this booklet issued by the U.S. Children's Bureau: "Are you training your child to be happy"? Or does he really mean that there are some pamphlets and some lecturers that do more harm than good? One can easily agree to that. Indeed, how else has our traditional morality been popularised?

I am, Sir, yours faithfully,

Santa Va., N.M., June 17th. ROSSLYN EARP.

PUBLIC HEALTH

The Infectious Stranger

IT is the duty of local authorities to provide hospital treatment for the infectious diseases of inhabitants of their own area, but apparently they have no such legal obligation as regards visitors who normally live elsewhere. Similarly, they are not obliged to arrange or pay for the care of those of their own residents who develop infectious diseases while staying in some other district. Thus no one is really responsible for patients who are unwise enough to fall ill while absent from their own locality, and, as one might expect, there have been cases in which a good deal of trouble has arisen from authorities disclaiming responsibility and sending infectious patients back to the reluctant care of the bodies under whose auspices they ordinarily dwell. It is to obviate any further disputes of this kind that the Minister of Health has now issued the Public Health (Treatment of Infectious Diseases) Regulations, 1934. In an accompanying memorandum it is pointed out that the primary public purpose of the hospital treatment of infectious disease is to prevent the spread of infection, and as the population exposed to the risk is the population of the area in which the disease is discovered, "it is generall recognised that the proper course is for the authorit of that district . . . to provide the necessary trea ment." To send people back to their homes when the clearly require hospital care is detrimental to publ health both by delaying treatment and riski dissemination. The regulations accordingly provi that authorities shall have the same powers and dut (in relation to the provisions of hospitals, &c.) respect of strangers as in respect of their o inhabitants. This will not, of course, affect right of an authority to decide on the advice of medical officer what cases shall be treated in hospi but it is intended to secure that the decision shal based on medical considerations alone, with a to the most effective control of the disease and best use of the accommodation available.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK E
JUNE 23RD, 1934

Notifications.—The following cases of infe disease were notified during the week: Small-p (last week 3); scarlet fever, 2363; diphtheria, enteric fever, 17; acute pneumonia (prima erperal fever, 43; puerperal yrexia, 118; cerebro-spinal fever, 20; acute poliomyelitis, 6; acute polio-encephalitis, 3; encephalitis lethargica, 6; dysentery, 14; ophthalmia neonatorum, 81. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on July 2nd–3rd was as follows: Small-pox, 3 under treatment, 1 under observation (last week 5 and 0 respectively); scarlet fever, 1615; diphtheria, 1588; measles, 1331 (last week 1547); whooping-cough, 282; puerperal fever, 25 mothers (plus 8 babies); encephalitis lethargica, 268; poliomyelitis, 2; "other diseases," 208. At St. Margaret's Hospital there were 15 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there were no deaths from small-pox or enteric fever, 23 (5) from measles, 6 (1) from scarlet fever, 33 (3) from whooping-cough, 30 (9) from diphtheria, 27 (8) from diarrhœa and enteritis under two years, and 24 (5) from influenza. The figures in parentheses are those for London itself.

Four of the deaths from measles were in Gateshead and 3 in Sheffield. Four fatal cases of whooping-cough were reported from Liverpool. There were 7 deaths from diphtheria in Leeds and 3 in Liverpool. Influenza was given as the cause of 4 deaths in Manchester, and 4 of the fatal cases of diarrhœa and enteritis were in Birmingham.

The number of stillbirths registered during the week was 260 (corresponding to a rate of 40 per 1000 total births), including 37 in London.

OBITUARY

ARTHUR BERNARD CRIDLAND, F.R.C.S. Edin.

CONSULTING OPHTHALMIC SURGEON, ROYAL HOSPITAL, WOLVERHAMPTON

We regret to announce the death of Mr. Bernard Cridland, which occurred on June 29th at Salisbury House, Wolverhampton.

MR. CRIDLAND

[Photograph by Bennett Clark

Arthur Bernard Cridland was born in Bristol and educated at Clifton College and University College, London, proceeding for his medical training to St. Mary's Hospital. He took the English double diploma in 1898 and proceeded a few years later to the F.R.C.S. Edin., and at the beginning of his career manifested the direction which his professional activities would follow, becoming at once house surgeon to the Bristol Eye Hospital and, later, anæsthetist with charge of the ophthalmic wards at the Royal Infirmary, Bristol. He then commenced his long association with Wolverhampton, where he was pointed ophthalmic surgeon to the Royal Hospital d to the Wolverhampton and Midland Counties e Infirmary. The skill and assiduity of his work de an early mark, and he soon gained a large ctice and became recognised as an authority on effects and treatment of injuries of the eye as erved in a large industrial town. He was mainly rumental in bringing the tonometer into regular in England. His special qualities were much by the fact that he was a thoroughly sound und surgeon. He now made a position in the almological world through his association with ruitful labours carried on at Oxford, and testified y the success of the annual ophthalmological ess in that city. This association commenced 10, when he took the D.O. Oxford diploma, n 1914, in succession to the late Sydney enson, he became secretary to the Congress. ties in connexion with this post he discharged years, and it is generally admitted that the importance and popularity of these annual meetings is mainly due to Cridland's effective and continuous work, discharged with a certain charming personal care. He was Master of the Congress from 1929 to 1931, and in 1933 delivered the Doyne Memorial Lecture in which he summarised his valuable investigations on the aftermath of cases of intra-ocular foreign body. This was a practical piece of work, and will be found in full in the Transactions of the Ophthalmological Society (vol. liii., 1933). The chances of restored ocular function in these cases, which so often have tragic issue, were well summarised, and the conclusions based upon a vast number of recorded accidents. It happens, most pathetically, that in the series of articles entitled "Prognosis" now running in our columns, one of the next to appear will be from Cridland, the subject being the outlook for patients suffering from perforating injuries of the eyeball, a subject which he may be said to have made his own. As was inevitable, Cridland became deeply interested in welfare work for the blind; he was the British representative on the Council of the National Association for the Prevention of Blindness, and the mitigation of distress among our blind population was always near his heart. He was this year senior vice-president of the Ophthalmological Society of the United Kingdom and would have succeeded to the chair in due course, and he was also vice-president of the Council of British Ophthalmologists and honorary member of the French Ophthalmological Society. By no means a profuse writer, what came from his pen was always a record of practical experience, and his papers will be found for the most part in the *British Journal of Ophthalmology*.

n
o.

Bernard Cridland will be equally regretted by all his fellow workers and scientific colleagues and by a large circle of patients and friends. He was a golfer, a motorist, and a fisherman, while his wide connexion with his professional specialty was due largely to his work at the Oxford Ophthalmological Congress, whose meetings displayed his fine personal qualities. "That Congress," writes one of his friends, "brought out all that was great and lovable in the man. It was a pet child of his and he spared neither time nor energy in promoting its welfare and success. He acted as secretary to the Congress for many years, and no more perfect secretary could have been found; genial, friendly to all, he never seemed to forget a name or a face. He was never harassed and never fussed. He was most ambitious for the high standard of the Congress, and it is mainly due to his devotion that it has reached its present position. It is tragic that his death should have occurred on the eve of its meeting."

WILLIAM ARTHUR VALENTINE, M.D. Dub.

The death is announced at Appledore, North Devon, of Dr. William Valentine, one of the best known practitioners in his district. He was born in County Fermanagh 65 years ago, and received his medical education at the University of Dublin. He graduated in arts and took the M.B., B.Ch. degrees in 1891, and three years later proceeded to the M.D. He settled in practice at Appledore in 1898, and in due course came to hold many public posts. He was district medical officer for the Northam district, M.O.H. to the Barnstaple port sanitary authority, surgeon agent to the Admiralty, medical inspector of seamen for the port of Bideford, and surgeon to the Bideford and District Hospital.

As quite a young man Dr. Valentine had been interested in the volunteer movement; he became M.O. to his territorial battalion, and on the outbreak of war proceeded with a division of the Devonshire Regiment to India. Later he served in France with the Royal Fusiliers, and in the closing phase of hostilities he was attached to the Serbian Army in Salonica. He came in for a warm tribute as a soldier-doctor in a book by Major Cecil Alport, recently reviewed in these columns, and entitled "The Lighter Side of the War." He is spoken of there, in ref to his work at Salonica, as "just the sort of d we required, especially as he had already seen se in France. He was well over age . . . he jo us and spent the last two years in the Near E doing very excellent work indeed . . . a good m and a stout fellow this." For his services in Saloni Valentine received the Serbian Order of St. Sav and was appointed a Knight of the Redeemer o Greece. He always cherished the greatest affectio for the 1/6th Battalion of the Devonshire Regiment, at whose annual reunion in Barnstaple he was a highly popular figure. He was a prominent member of the British Medical Association, acting as chairman of the North Devon Division and as a member of the representative body, while he was nominated last year as president-elect of the S.W. branch, but was unable through failing health to take up election, which occurred just before his death.

Dr. Valentine was keenly interested in lifeboat work at Appledore. He was also an experienced yachtsman, having been vice-commodore of the Taw and Torridge Sailing Club. His wife predeceased him, but he leaves two sons, one of whom succeeds to the medical practice in Appledore.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Royal Assent

In the House of Lords on Thursday, June 28th, the Royal Assent was given to a number of Acts, including the Unemployment Act, the Mines (Working Facilities) Act, and the London County Council (General Powers) Act.

Bills Advanced

In the House of Commons on June 28th the Road Traffic Bill passed through Committee and was considered on Report. On the following day (Friday, June 29th) the Bill was read the third time. On Thursday, June 28th, the South Devon and East Cornwall Hospital, Plymouth, Royal Hospital, Devonport and Central Hospital, Plymouth (Amalgamation, &c.), Bill was read the third time.

HOUSE OF COMMONS

THURSDAY, JUNE 21ST

Poor-law Relief in Scotland

Mr. Kirkwood asked the Secretary of State for Scotland the total number of persons in Scotland on able-bodied and poor relief as at May, 1934, compared with May, 1933; and what was responsible for the abnormal increase.—Sir Godfrey Collins replied: The number of persons, excluding dependents, in receipt of ordinary poor relief in Scotland at May 15th in the years 1933 and 1934 were 90,959 and 98,193, respectively, an increase of 7·9 per cent. The corresponding figures for persons in receipt of able-bodied relief were 43,348 and 72,338 respectively, an increase of 66·8 per cent. With regard to the latter part of the question, the hon. Member will see that there have been increases in both cases. As regards the ordinary poor, the cause of the increase would appear mainly to be the cumulative effect of the long continued industrial depression in exhausting resources available for the support in working-class families of non-able-bodied members of the family. With regard to the much greater increase of the able-bodied who are receiving relief, I am informed that 91 per cent. of this increase has occurred in Glasgow and Greenock where the rates of relief were recently increased, involving the addition to the poor roll of persons whose unemployment insurance benefit and transitional payments are being supplemented.

WEDNESDAY, JUNE 27TH

Diphtheria Immunisation

Mr. Groves asked the Minister of Health (1) what was the child population of Dagenham at the following ages: up to 5, 6 to 10, 11 to 15; how many Dagenham children at each of these age-periods had received three injections of the diphtheria immunising mixture in each of the years 1931, 1932, and 1933; how many of these were subsequently Schick tested; and how many of those Schick tested were found negative as a result of the test; and (2) how many cases of diphtheria were notified in Dagenham in the year 1931.—Sir Hilton Young replied: The child population of the Dagenham urban district at the ages referred to by the hon. Member was, at the census of 1931, (1) up to 5—15,954; (2) 6 to 10—15,503; (3) 11 to 15—8559. As regards the remainder of the question, the following is the information furnished by the local authority. The figures for immunisation and testing for any year may not strictly correspond as children immunised in any year are not necessarily Schick tested in the same year.

Age-period.	Children who received three injections of immunising. mixture.			Children Schick tested after immunisation.			Children found negative on Schick testing.		
	1931	1932	1933	1931	1932	1933	1931	1932	1933
Under 6 years..	499	234	193	—	253	88	—	194	85
6 to 10 ..	480	300	163	—	402	160	—	305	145
11 to 15 ..	190	102	70	—	171	50	—	132	34

The number of cases of diphtheria notified in the urban district in the year 1931 was 207.

Mr. Groves asked the Minister of Health whether he was aware that, in a speech to sanitary inspectors, the deputy medical officer of health for Leeds admitted that 8 per cent. of the children inoculated by him with toxoid, with a view to preventing diphtheria, had suffered very severe reactions; and whether he would reques. officers of health who were responsible for the intro of this system to report to him all such serious i of the inoculations, together with information regar the material used.—Sir HILTON YOUNG replied: I a advised that the remarks to which the hon. Member refer related only to the use of powerful forms of diphtheria prophylactic employed to induce rapid immunisation. The speaker, therefore, stressed the importance of applying a preliminary test which would discover the possibly severe reactors, and of immunising these by the ordinary routine method. In the circumstances, the action suggested in the last part of the question does not appear to be called for.

Inoculation and Parents' Consent

Mr. GROVES asked the Minister of Health whether he would advise all medical officers of health to ensure, when arranging schemes for any form of inoculation of school-children or children attending clinics, that no child be inoculated without the written consent of its parent or guardian.—Sir HILTON YOUNG replied: Advice of this kind has always been given in the official memoranda issued by my Department on this subject, and I have no reason to suppose that it is not generally followed.

THURSDAY, JUNE 28TH

Miners' Nystagmus

Mr. TINKER asked the Home Secretary if his attention had been draw to cases where mine workers who had been suffering from nystagmus had been declared recovered by the medical referee and fit to resume their former occupation, but had been refused employment on the grounds that they were liable to contract nystagmus again; and if he would consider amending the Workmen's Compensation Act so as to entitle them to compensation when they could prove they were deprived of employment because of having suffered from this disease.—Sir JOHN GILMOUR replied: Nystagmus is not the only injury or disease in view of which employers may be unwilling to take the risk of re-engaging the workmen for his old work when he has become physically fit for it; and the question whether in such circumstances it is desirable, and indeed in his own interests, that the workman should be entitled to further compensation is by no means a simple one. Various other proposals have been made for modifying the conditions under which compensation is payable for this disease, and a full inquiry would be necessary before the question of amending legislation could be considered.

Mr. TINKER: Is the Minister aware that the House of Lords on June 11th decided a case of this character, and that it is imperative that something should be done because the men have no right to claim compensation and cannot get work when they are suffering from this disease? Surely the time has come when we should protect men in cases like these?

Sir J. GILMOUR: If I were satisfied that there was a general demand in the mining industry for an inquiry into this subject I would be prepared to set up a committee.

MONDAY, JULY 2ND

Medical Practitioners in Palestine

Mr. WEDGWOOD asked the Secretary of State for the Colonies (1) whether and, if so, why new immigrant doctors into Palestine were restricted to five a year; and whether there was a limitation on the numbers of doctors or lawyers allowed to practise in any other British Colony or Dominion; and (2) whether there were any and, if so, what restrictions on the number of Jewish refugees from Germany practising as doctors in Palestine; and, if so, who asked for the restriction.—Sir P. CUNLIFFE-LISTER replied: In March last the Executive of the Jewish Agency in Palestine was informed of the proposal of the Palestine Government to institute measures for the limitation of the number of licences to be issued annually to doctors, dentists, and advocates. I am not aware that any request for such restrictions had been ade. No legislation has yet been enacted to give effect these proposals, which are at present the subject of espondence between the High Commissioner and lf. So far as I am aware, no similar system of ion exists in other British Dependencies or in the erning Dominions.

Quinine Stocks in India

ess of ATHOLL asked the Secretary of State for e would explain why 300,000 lb. of quinine owne Government of India were lying idle; for how lo d been the case; and what arrangements were no ntemplation for making this stock of quinine a for the millions who annually suffered from mala could not procure it.—Sir S. HOARE replied: The ment of India habitually maintain a reserve stock ine for emergencies. This reserve rose to 300,000 t 1926 and continued at or above that figure until 1 Measures have since been initiated to reduce it to 150, which is regarded as a sufficient reserve. In March, 1 had been reduced to 28[illegible],759 lb. I have no later figure, I understand that the Government of India are doin ir best to increase [illegible]les. I will ask them for a furt eport with reference to the last part of the question.

Disposal of Lo n Refuse

Sir FRANCIS FREMANTLE askea he Minister of Health whether the Advisory Committee n London Refuse had yet reached any conclusions for the improvement of the disposal of refuse; and what action the Ministry of Health proposed taking in the matter.—Sir HILTON YOUNG replied: I understand that the draft of an interim report is now being considered by the committee. I hope that the committee can complete this report at an early date.

Bonus and Salary in Civil Service

Mr. JOHN WILMOT asked the Chancellor of the Exchequer if he could make any statement as to the intention of the Government with regard to the consolidation of bonus and salary in the Civil Service.—Mr. DUFF COOPER (Financial Secretary to the Treasury) replied: It is a matter of regret that the negotiations on this subject on the Civil Service National Whitley Council have resulted in the inability of the staff side to enter into an agreement with the official side on the basis of the proposals made by them with the approval of the Government. The Government have accordingly reviewed the whole position in the light of all the circumstances. They are satisfied that the proposals made are fair and reasonable and that it would be right to put them into operation from July 1st. An announcement to this effect was accordingly made at the meeting of the National Whitley Council on Friday, June 29th, and detailed instructions will be issued at an early date.

The following is a summary of the proposals in broad outline:—

Consolidation will be effected as from July 1st, 1934, on the terms set out in paragraphs 352, 355, and 356 of the report of the Royal Commission on the Civil Service, or with reference to a cost of living figure of 55, whichever is more favourable, with the proviso that the remuneration so arrived at shall remain subject to abatement at the appropriate rates so long as half the emergency reductions continue in force. In other words, the pay of a civil servant, hitherto remunerated by means of basic pay plus cost of living adjustment under the stabilisation agreement, will be measured (for so long as half the emergency reductions remain in force) as half-way between his pay under that agreement and the consolidated pay which would result from the full application of the consolidated scheme. In all cases of established civil servants retiring on or after July 1st, 1934, the full consolidated rate will be deemed to be the annual salary and emoluments of the office within the meaning of Section 2 of the Superannuation Act, 1859, by reference to which pensions, additional allowances, and gratuities will be calculated. In accordance with the terms of Section 4 of the Superannuation Act, 1887, awards of gratuities

ADDRESSES AND ORIGINAL ARTICLES

VIRUSES IN RELATION TO THE ÆTIOLOGY OF TUMOURS *

By C. H. Andrewes, M.D., M.R.C.P. Lond.
MEMBER OF SCIENTIFIC STAFF, NATIONAL INSTITUTE OF MEDICAL RESEARCH

This subject, the ætiology of tumours, is rather far removed from those dealt with by previous Oliver-Sharpey lecturers. It is also one which has tended to engender unnecessarily bitter arguments amongst those who discuss it. Nevertheless it seems to me that the parasitic theory of cancer needs to be carefully reconsidered in the light of our growing knowledge about viruses; and some recent work I shall have to refer to makes the subject particularly ripe for discussion at the present time.

I do not propose to attempt the difficult feat of providing proof that mammalian tumours are caused by viruses: that is something which cannot be done to-day. I shall content myself with a more limited but quite definite objective, that of persuading you that the parasitic hypothesis of cancer is not dead but very much alive. I shall try to show that many of the known facts about tumours are *consistent* with the view that the behaviour of tumour cells is essentially due to infection of those cells by a parasitic virus: further, that certain facts are difficult to reconcile with any other view. On the other hand, I shall have to discuss certain features of neoplasms which are very hard to explain on the virus hypothesis and to consider several attempts which have been made to reconcile apparently discordant facts.

Let us first inquire why viruses are worth considering at all in relation to tomours. Cancer has been considered as a parasite since the earliest times, and many would still so consider it, regarding the cancer cell itself as of parasitic nature. But with the discovery of bacteria and protozoa in the last century there began to appear a host of claims that specific micro-organismal parasites had been seen in or cultivated from tumours. None of these claims has stood the test of time and interest in the parasitic theory of cancer has accordingly waned. Recently, however, the theory has arisen once more, phœnix-like, in the form of what is called the virus hypothesis. It is widely believed that the viruses constitute a group of very small organisms adapted to a parasitic existence within cells of animals and plants, and this conception has naturally excited interest once more in the possibility of a relationship between the viruses and benign and malignant neoplasms.

Filtrable Tumours of Fowls

In considering this subject we naturally think first of all of the filtrable fowl sarcomata. In 1910 began to appear the studies of Rous and Murphy and their associates on fowl sarcomata, tumours which are transmissible by means of cell-free filtrates. But the seed fell upon stony ground and no general interest was taken in their observations. The edition of Ewing's well-known "Neoplastic Diseases" published in 1919 contains a 13-page chapter on "the parasitic theory of cancer" in which the word "virus" does not occur. Rous's sarcoma is dismissed elsewhere in the book as a disease sui generis.

But during the last decade interest in the filtrable fowl tumours has steadily increased. The salient facts about these tumours are as follows. In general they resemble mammalian sarcomata, infiltrating locally and metastasising to distant parts of the body; reasons for believing them to be true tumours will be discussed presently. They are of several different histological types including spindle-celled sarcoma, osteochondrosarcoma, endothelioma and so on, covering all the range of mammalian connective tissue tumours. No filtrable epithelial fowl tumour has, however, been described as yet. The best-known fowl tumour is the Rous No. 1 spindle-celled sarcoma.[1] In view of the many different tumours which have now been described it is incorrect to speak of all filtrable fowl tumours as Rous sarcomas or Rous tumours; such a terminology suggests that all are alike. These growths differ essentially from mammalian tumours in one property: they can be transmitted by filtrates or desiccated material containing no formed cell-elements. The active agent in these filtrates or desiccates is generally regarded as a virus; its claims to be considered as such will be discussed later. The fowl tumours differ also from mammalian growths in that some of them will grow progressively when inoculated into adults of a foreign host, such as pheasants or ducks. Mammalian neoplasms cannot be propagated in a foreign species unless very young animals are used.

The importance of these tumours rests largely on the fact that their existence renders untenable most of the arguments which had been built up to show that the parasitic theory of cancer *could* not be true. These arguments ran along lines such as these: the age-incidence of cancer is unlike that of parasitic diseases; the anatomical and physiological characters of cancer tissue differ from those of infectious processes; abnormally large size of cell and nucleus, so common in cancer, is not the rule in inflammation; a cancer continues to grow at the expense of the body in a way which has no parallel in any other condition; the fate of metastases of cancer is entirely different from that of infective emboli; tumour tissues are transplantable to a new host in a manner unlike that of any other tissues, and so on. Rous's work showed that fowl tumours which were produced by the action of a virus-like agent resembled classical tumours in all of the points discussed. In other words, all these theoretical objections to a parasitic theory of cancer fell to the ground.

One not infrequently hears this argument: it is agreed that a virus may cause certain tumours, but this finding is considered to be on the same footing as the causation of tumours in rats affected by worm-infestation or the production of epitheliomata in mice by tar and other chemical agents. "Viruses, worms, tar—all these agents can produce cancer. Why not maintain that all tumours are caused by worms; it is as reasonable as postulating a virus for every new growth!" Those who reason thus miss the essential differences between the rôle played by the virus and the rôle of, let us say, the tar. The tar only produces tumours after a long latent period; the virus of the Rous sarcoma acts almost immediately, and malignant changes can be seen only a few days after inoculation. Again, tar acts only by initiating a cancerous change; it is not multiplied in the growth nor recoverable from metastases or transplanted tumours; the fowl tumour viruses multiply as the tumour multiplies and can be obtained from it after many transplantations. The tumours gives no clue to suggest that in them either is there an extracellular agent. The rare cases of carcinoma sarcomatodes, instances of apparent malignant transformation of the stroma of an epithelial tumour may be significant.

---

* The first Oliver-Sharpey lecture for 1934, delivered before the Royal College of Physicians of London on May 1st. The second lecture will appear next week.

MOUSE SARCOMA 37S

In one of the Imperial Cancer Research Fund's mouse carcinomata (37) such a transformation of stroma apparently occurred, and from this has been obtained a sarcoma known as 37S. Workers with this tantalising tumour seem always on the point of showing that it can be transmitted by a cell-free agent, but the evidence is never quite convincing enough. First, Gye[31] found that one strain of this tumour (polymorph 37) would grow in very young rats in a free manner not usual with heteroplastic grafts. He did not provide proof, however, that the tumours consisted of rat cells and not of mouse cells. Secondly, it was reported, again by Gye,[32] in 1925 that Berkefeld filtrates of diffusates of 37S would produce sarcomas in mice. These experiments appeared conclusive; unfortunately neither Gye nor other workers have been able to repeat them. It is conceivable that, just as Rous No. 1, usually filtrable, passes through phases of poor growth and non-filtrability, so 37S, usually non-filtrable, occasionally reaches maximal virulence and is then filtrable. Unless and until the tumour can be filtered again we cannot decide. Thirdly, Cramer[8] found in 1930 that 37S, unlike mouse carcinomata, would still produce tumours after being frozen and thawed eight times; he could obtain no evidence that living cells were present after this treatment. Gye and Purdy,[33] however, investigating histologically the fate of grafts of such material, thought it probable that some cells were living after four freezings and thawings. Fourthly and lastly, Tinozzi[34] produced tumours by inoculating into other mice minced embryos taken from pregnant mice bearing 37S sarcomata; he believed that transplanted cells could not be held responsible for the growths, particularly as the placentæ gave negative results.

The Natural History of Viruses

We must turn aside for a short time to consider some general properties of viruses in an endeavour to see whether viruses can reasonably be expected to be capable of giving rise to tumours. Such digression may seem unnecessary since I have already argued that some viruses, those of the fowl sarcomata, not only might reasonably be expected to cause but actually do cause true new growths. The matter is, nevertheless, important to discuss in view of the doubts to be dealt with later as to whether the fowl tumour agents are really viruses. Most virus diseases are short, acute, self-limited infections; measles, mumps, chicken-pox, and small-pox at once occur to the mind. Is it or is it not reasonable to seek for the cause of cancer amongst agents producing infections of such a type?

INTRACELLULAR HABITAT OF VIRUSES

It seems fairly certain that many viruses multiply within the cells of the host. The cytoplasmic inclusions of many viruses of the pox group consist of aggregations of particles which probably represent the virus bodies themselves. The studies of Borrel,[35] Goodpasture,[36] and of Barnard[37] on the viruses of fowl-pox, canary-pox, and ectromelia (a virus disease of mice) may be quoted. The antibodies in resistant animals which neutralise viruses possibly act by altering their physical state so that they cannot penetrate or infect susceptible cells. In any case, it appears that once a virus is inside a cell, antibody in the fluids outside the cell is unable to neutralise it nor to prevent it from multiplying. This has been shown by studies of viruses (herpes simplex, virus III., yellow fever) growing in tissue cultures. Certain viruses will produce characteristic inclusion bodies in cells infected in vitro in tissue cultures. If the tissues are suspended in immune serum no infection of the cells can take place; but if virus is given opportunity to infect the cells before antiserum is added, then the typical inclusion bodies are able to develop (Andrewes,[38 39] Haagen[40]). Rous, McMaster, and Hudack[41] have lately shown the same thing more directly. Suspensions of rabbit fibroblasts were obtained by digesting tissue cultures with trypsin. The viruses of vaccinia and of Shope's rabbit fibroma (to be mentioned shortly) were adsorbed to these cells. The virus-treated cells were then suspended in antisera for the respective viruses and later washed. It was found that the sera had been unable to neutralise the viruses adsorbed to the cells, while virus unprotected by cells was quickly inactivated. Similarly Perdrau and Todd[42] found that many viruses were inactivated by methylene-blue in the presence of light. Virus in cell suspensions from infected tissues was, however, protected by its intracellular position from this photodynamic destruction.

These facts have a definite bearing on the virus theory of tumours. We have to explain why a hypothetical cancer virus is not destroyed by neutralising antibodies as the viruses of measles and chicken-pox presumably are during convalescence. If our cancer virus were to exist in a state of equilibrium with the parasitised cell, stimulating it to divide but not destroying it, it would clearly never have to come into the open where antibodies could get at it. Secure in its stronghold it could defy the dangers without.

A possible reason for the persistence of virus III. in the Brown-Pearce rabbit tumour is now apparent. If cells in such a tumour are multiplying rapidly enough, extraneous viruses in the cell may find themselves carried to daughter and then to grand-daughter cells, yet not necessarily reaching a high enough concentration to produce cell death. They need thus never be brought into contact with the immune serum which could eliminate them from the scene of action.

At this point I must digress for a few moments in order to avoid possible misconceptions. We have had to consider immunity to viruses in our endeavour to understand how viruses could cause new growths. But immunity to tumours is probably a complex phenomenon, by no means to be wholly explained in terms of immunity to a virus. Much work has been done on immunity to transplanted tumours in mammals, which is really a question of immunity against the cells of a foreign individual and does not greatly concern us to-day. Then there has to be considered the mechanism by which regression of established new growths occurs. Relative immunity to a tumour virus itself may also be involved, perhaps in determining whether a spontaneous tumour does or does not arise at all.

Many clinical and experimental data are available bearing on immunity to tumours; for instance, there is the vexed question of whether multiple primary new growths occur with more or less than the expected frequency. But these and other facts are of such doubtful interpretation that they seem at present hardly relevant to a discussion of the virus hypothesis.

Pathological Changes Produced by Viruses

The lesions which viruses produce consist firstly, of changes in the cells which are primarily attacked, and, secondly, of the inflammatory reactions which follow.

We are at present concerned only with the primary response of the parasitised cells. In these, viruses cause either proliferation or necrosis or, very often, proliferation accompanying or followed by necrosis. One also sees in many instances the formation of cytoplasmic or intranuclear inclusion bodies, and these inclusions may be found, as in vaccinia and fowl-pox, in cells actually engaged in mitosis. Often the proliferation is early and comparatively slight: necrosis sets in quickly. With other viruses the proliferative changes dominate the picture. Proliferation and necrosis are, of course, seen in many inflammatory conditions caused by bacteria or by non-living agents; their interest in virus diseases depends upon the evidence that in these instances they are caused by a parasite within the cell.

One can point to examples of every type of change produced in cells by the action of a virus, from pure necrosis to almost pure proliferation. If one agrees provisionally to consider tumours as a group of virus diseases one can construct in this way an ordered series of virus lesions extending from small-pox to cancer. The cell involved may be epithelial or of connective tissue origin. It happens that at the "tumour end" of our scale we find a more beautifully graded series amongst the disorders of the connective tissues; at the other end the infections of the epithelial cells are better represented (see Table). Nevertheless, it will be better to consider the two series separately to start with.

Necrosis to Neoplasia

Epithelial series.	*Connective tissue series.*
Foot-and-mouth disease.	Canary-pox.
Vaccinia.	Vaccinia.
Fowl-pox.	Infectious myxoma (rabbit).
Sheep-pox.	
Molluscum contagiosum.	Infectious fibroma (cottontail).
Filtrable warts (man, dogs, cattle).	Fujinami sarcoma (duck).
Filtrable warts (rabbits).	Fujinami sarcoma (fowl).
Non-filtrable papillomata.	Rous sarcoma No. 1.
Rodent ulcer.	Mill Hill 1 fibrosarcoma.
Malignant epithelioma.	Non-filtrable fowl sarcoma.
	Mammalian sarcoma.

FROM NECROSIS TO NEOPLASIA: THE EPITHELIAL SERIES

Foot-and-mouth disease affords an example of a virus which produces in the cells attacked necrosis almost without preliminary proliferation. Small foci of epithelial cells become degenerated, and the spreading of this necrosis gives rise to the formation of a vesicle.

The lesions produced by vaccinia show varying combinations of cell destruction and multiplication. In the rabbit's testis the virus produces necrosis of epithelium without proliferative lesions. In the skin of the calf the degenerative process is almost unaccompanied by proliferation. But on the cornea of the calf or rabbit lesions of both types are seen. Within a few hours after inoculation one can find enlargement of individual epithelial cells and also mitotic and amitotic multiplication. The intracellular Guarnieri bodies also appear in many cells within a few hours. After a few days degenerative changes are more evident and many of the cells containing Guarnieri bodies have been engulfed by normal epithelial cells. Proliferative processes in this instance seem to precede degeneration, but the exact relations of the two are hard to disentangle.

In fowl-pox also we find multiplication of affected cells preceding destruction. So great is the growth of tissue here that nodules of considerable size are formed; hence the name epithelioma contagiosum. After the initial proliferative changes, inclusion bodies, larger than those of vaccinia, appear in the cells, which themselves become much enlarged. Mitosis, however, may still occur in cells containing these bodies. Finally the cells are killed and degenerative changes predominate. The lesions of human molluscum contagiosum bear a close resemblance to those of fowl-pox. The visceral lesions of sheep-pox are at first sight extraordinarily suggestive of a neoplastic process (Bosc,[43] Borrel[44]); they take the form of adenomatous nodules in the stomach, lungs, and even in the mammary gland of the affected sheep. Inclusion bodies occur in the cytoplasm of the proliferating epithelial cells and numerous mitoses may be found, many of them atypical. The alveoli in the pulmonary lesions are full of swollen cells apparently formed from multiplication of altered cells lining their walls.

Infectious warts of man have their parallel in similar conditions in dogs and cattle. Here we find that the lesions, which again are caused by a filtrable agent, are for some time entirely proliferative. There is no general agreement as to whether inclusion bodies are present in human warts. After growing for some time, warts, both in man and in dogs, are apt to regress rather suddenly, and the host is then commonly immune to reinoculation. Shope[45] has described "infectious papillomatosis" as occurring in wild cottontail rabbits in America. While the warts of man and dogs have not been proved to be transferable to species other than their natural hosts, Shope succeeded in infecting domestic rabbits with his cottontail warts. (The domestic rabbit is of a different genus from the cottontail.) Cottontail warts are perhaps one stage nearer a true tumour than are other warts, for they seem to go on growing indefinitely, showing so far as is yet known neither a tendency to regression nor to the development of malignancy†; they may become as large as a human fist. While Shope readily infected domestic rabbits with material from cottontails, he found great difficulty in transmitting these warts in tame rabbits, rapidly though they were growing, to other tame rabbits. He points out that in so far as they are—in the tame rabbit—not filtrable and not even propagable by grafting they are exactly comparable with many spontaneous epithelial tumours of mammals.

It will not be hard to continue the series of epithelial growths from the progressive cottontail papilloma, through various non-filtrable papillomata of man and animals, till we reach those of local malignancy, such as a rodent ulcer and finally a fully malignant human epithelioma. The suggestion that epithelial new growths do not necessarily constitute a class apart from other disorders of epithelial cells was made over thirty years ago by Borrel.[44] In an admirable paper entitled Infectious Epithelioses and Epitheliomas, published in 1903, he compared the proliferative lesions of vaccinia, sheep-pox, and molluscum contagiosum with those of mammary cancer in the mouse.

FROM NECROSIS TO NEOPLASIA: THE CONNECTIVE TISSUE SERIES

When we turn to the virus diseases attacking the connective tissues we naturally find it harder to distinguish between the primary injury inflicted by a virus on the cells and the results of the secondary inflammation. Accumulation of wandering cells and multiplication of various types of cells, both mobile and fixed, makes us chary of maintaining that the specific stimulus of a virus has [illegible] of one type of connective tissue cell; and clearly it is only a definite stimulation of one type of cell which we can compare with a tumour; anything else would have to be classed as an infective granuloma.

---

† Since this lecture was delivered a note by Rous and Beard has appeared in Science (1934, lxxix., 437); they report that warts grafted as autoplasts into the internal organs of rabbits show many of the features of malignancy.

As an example of a virus producing necrosis of connective tissues we may point to the canary virus described by Kikuth and Gollub[46] and shown by Burnet[47] to be related to fowl-pox. This virus attacks epithelial as well as connective tissues; on subcutaneous or intramuscular inoculation it produces acute local œdema and necrosis. The involved mononuclear cells show vacuolation and there is little doubt that the virus multiplies locally in them.[47]

The lesions of vaccinia also are not confined to epithelial structures. With at any rate some strains of the virus, proliferation of endothelial cells is a striking feature of the histological picture. This is seen in the small vessels in a skin lesion, and in the spleen and the so-called lung pocks of generalised vaccinia in the rabbit. Endothelial proliferation occurs, however, in so many pathological conditions that one hesitates to stress unduly these vaccinial lesions; there is no certainty that the virus is multiplying in the affected cells.

Infectious myxoma of the rabbit is a highly contagious fatal disease of rabbits first described from South America. But besides acute conjunctivitis and other signs of inflammation, the affected rabbits show tumour-like myxomatous masses in the subepidermal tissues and in the lymph-nodes. These myxomata contain large stellate or polygonal cells which appear, according to Rivers,[48] to have multiplied under the stimulus of the virus. In the lymph-nodes they possibly arise from the reticulum of the gland. Mitoses are present in the lesions though not numerously. At the end of his paper describing the pathological changes in this disease, Rivers writes as follows:—

> "If, as some believe, the Rous sarcoma appears to be more closely related to true neoplasms than to diseases induced by highly contagious agents, then the myxoma, upon further study, may serve to bridge the gap between the Rous tumor and other virus maladies, and to indicate that, after all, no great difference exists between tumor-forming viruses and those causing vesicular or destructive lesions."

Another disease which may further help to bridge the gap is the infectious fibroma lately described by Shope.[49] This, like the infectious wart, naturally occurs in wild cottontails and is transmissible also to laboratory rabbits. In the cottontail one finds subcutaneous fibroma-like lesions which only regress after many months. On injecting such material —or filtrates from it—into the testes or subcutaneous tissues of tame rabbits, Shope found that similar fibromatous lesions developed. They were white, rubbery in consistence, and histologically showed masses of spindle-shaped or polygonal cells, often in whorls; mitoses were scarce. Dr. Shope kindly sent me some of this virus and I have studied histologically the early changes produced by it in a rabbit testis and can confirm his findings; the primary lesion is a proliferation of the connective tissue cells, though some polymorphs are usually to be found also. Later the picture strongly recalls a spindle-celled sarcoma. There is, however, no metastasis to distant organs, and the fibromata always ultimately regress. The condition was unexpectedly found by Shope to be related to infectious myxomatosis, some cross-immunity between the two diseases being present; the fibroma-like condition differs greatly from the other, however, in that infection of one rabbit from another has not yet been demonstrated. I found no evidence of cross-immunity between the fibroma virus and a true tumour in a rabbit; rabbits in which the epithelial tumour of Brown and Pearce had regressed were normally susceptible to Shope's fibroma virus.

The interest of this virus does not end here. For apparently a mutation or adaptation of the virus can occur when it is passed through domestic rabbits. As a result of this change it no longer produces cell proliferation and tumour-like swellings but causes fever, necrosis at the site of inoculation, œdema, hyperæmia, and acute outpouring of inflammatory cells. More than this, inoculated rabbits may develop on the shaved skin generalised pock-like lesions recalling those of generalised vaccinia in the rabbit. I have recently had under study three strains of the virus: (*a*) is but a little way removed from the original cottontail tumour and produces fibroma-like lesions often of considerable size; (*b*) causes no primary proliferation of connective tissue cells but only acute inflammation accompanied by generalised pocks; (*c*) is a mixed strain which gives rise to nodules of fibroma-like growth in the midst of inflammatory lesions but never to big tumours; it also frequently produces skin-pocks. So far as I can determine I am not dealing with a mixture of two distinct viruses. The inflammation-producing strain completely immunises against the tumour-causing strain and vice versa. Neutralisation tests with immune sera confirm this result. We have apparently to deal with a virus which in two phases of activity can produce what is very like a tumour—or what is more like an eruptive fever. The interest of such a virus to the present argument needs no emphasis.

The next example in our series is Fujinami's[50] myxosarcoma as it affects well-grown ducks. Filtrates of this tumour, which was originally of fowl origin, injected into the leg of an adult duck produce tumours which grow very rapidly and may reach almost the size of a tennis-ball before they begin to regress[51] as, in the end, they always do. They only show local malignancy and do not metastasise. Histologically the picture is that of a myxosarcoma. Clearly the state of affairs is not very different from that of one phase of Shope's rabbit fibroma. The tumour is propagable by means of filtrates, but only if tumours from young ducklings are used as the source of material. In these young ducklings the picture differs chiefly in that the death of the bird often occurs; possibly this results from mechanical causes, the tumours being large relatively to the size of the host. If filtrates of this same sarcoma of Fujinami's are injected into a fowl the events are at first like those in the duck; a local sarcomatous tumour develops. But instead of regressing after a week or two it continues to grow and the bird almost invariably dies. Metastases occur, chiefly in the lungs, liver, and heart. The tumour is propagable indefinitely by means of cell-free filtrates; it is in fact in most respects identical with the Rous No. 1 sarcoma.

We may next turn to the Rous sarcoma when in the state, already mentioned, in which it grows poorly and cannot be filtered.[7] We may point out that during these phases its behaviour is like that of a non-filtrable mammalian sarcoma. The fowl endothelioma of Begg (Mill Hill 2)[52] is still more apt to defy all efforts at filtration for long periods.

A next stage is seen in the slow-growing fowl fibrosarcoma Mill Hill 1, also described by Begg. For about three years after it was first propagated it formed such hard growths that it was impossible to make an extract wherewith to test filtrability. After a few passages it began to grow more rapidly and was finally found to be filtrable.[6]

From such a tumour it is not a difficult step to a fowl-sarcoma which has not yet been filtered, nor from that to a non-filtrable mammalian sarcoma.

In the course of these lectures I have frequently used the term "true tumour," but I do so against my better judgment. I neither affirm nor deny that, for instance, Shope's rabbit fibroma is a true tumour, for the more I consider the two pathological series just described, the less I know what a true tumour is. One can, of course, draw an arbitrary line anywhere in the series I have described if one chooses to define a tumour according to one criterion only, for instance, non-transmissibility by filtrates, power of infiltrating growth, power of progressive independent growth, ability to metastasise, or formation of tumour by multiplication of a single cell type. But if one believes, as most pathologists do, that a tumour is best defined by considering a number of criteria, then one cannot, so far as I can see, draw a sharp line across either of these two series; nowhere can one reasonably say "Below this line are tumours, above it are infections."

Metabolism of Virus Lesions

The work of Warburg and his collaborators on the carbohydrate metabolism of tumours has shown that these differ from normal tissues in the relatively large part played by anaerobic glycolysis as compared with aerobic oxidation or respiration. The facts brought to light have been used as the basis of theories of carcinogenesis. Crabtree[53] has applied Warburg's technique to the study of pathological overgrowths caused by viruses. Tissues from fowl-pox and from human warts showed essentially the same carbohydrate metabolism as Warburg found in tumours; so did material from Rous sarcoma. On the other hand, lesions from the skin of rabbits with vaccinia and from the brain of a guinea-pig with rabies showed no great deviation from normal. The abnormal metabolism appears to be associated with cell proliferation as such and not to be specifically associated with "true" tumours.

In this first lecture I have attempted to maintain that the behaviour of a tumour, *once the malignant change has begun*, is what might be expected of a virus disease in which there was a certain balance between the infecting parasite and the host-cell, so that neither tended to destroy the other. If this were all, the parasitic theory of cancer would be much more popular than it is. But difficulties at once arise when we turn our attention to the inception of the malignant change in a cell; and these difficulties we have to face in the second lecture.

PERINEO-ABDOMINAL EXCISION OF THE RECTUM IN ONE STAGE*

By W. B. GABRIEL, M.S. Lond., F.R.C.S. Eng.

SURGEON TO ST. MARK'S HOSPITAL, LONDON

CANCER of the rectum is one of the most hopeful of malignant tumours if treated by radical surgery, and one of the fascinations of the surgery of this region is the variety of operations which can be applied. This also constitutes a difficulty, for the operator has the responsibility of selecting the operation which he believes will be most suited to the particular case. In the light of our present knowledge it can be asserted that the operation of choice should be the most radical one that can be performed with reasonable safety to the patient; the patient's general condition, the extent of the growth, and its height above the anus, being the points which particularly need to be considered.

For many years there has been a controversy in this country regarding the merits of perineal excision of the rectum compared with the abdomino-perineal, and I think the present time is suitable for presenting certain facts which relate to this problem. There is a field of usefulness for each operation provided it is recognised that usually a combined abdomino-perineal or a perineo-abdominal excision (which latter, I venture to suggest, is the better method) is definitely more radical than a perineal excision. There are two possible exceptions to this rule.

(1) Those early cases in which there is a single small mobile carcinoma in the middle or lower thirds of the

virus on the cells and the results of the secondary inflammation. Accumulation of wandering cells and multiplication of various types of cells, both mobile and fixed, makes us chary of maintaining that the specific stimulus of a virus has led to proliferation of one type of connective tissue cell; and clearly it is only a definite stimulation of one type of cell which we can compare with a tumour; anything else would have to be classed as an infective granuloma.

As an example of a virus producing necrosis of connective tissues we may point to the canary virus described by Kikuth and Gollub[46] and shown by Burnet[47] to be related to fowl-pox. This virus attacks epithelial as well as connective tissues; on subcutaneous or intramuscular inoculation it produces acute local œdema and necrosis. The involved mononuclear cells show vacuolation and there is little doubt that the virus multiplies locally in them.[47]

The lesions of vaccinia also are not confined to epithelial structures. With at any rate some strains of the virus, proliferation of endothelial cells is a striking feature of the histological picture. This is seen in the small vessels in a skin lesion, and in the spleen and the so-called lung pocks of generalised vaccinia in the rabbit. Endothelial proliferation occurs, however, in so many pathological conditions that one hesitates to stress unduly these vaccinial lesions; there is no certainty that the virus is multiplying in the affected cells.

Infectious myxoma of the rabbit is a highly contagious fatal disease of rabbits first described from South America. But besides acute conjunctivitis and other signs of inflammation, the affected rabbits show tumour-like myxomatous masses in the subepidermal tissues and in the lymph-nodes. These myxomata contain large stellate or polygonal cells which appear, according to Rivers,[48] to have multiplied under the stimulus of the virus. In the lymph-nodes they possibly arise from the reticulum of the gland. Mitoses are present in the lesions though not numerously. At the end of his paper describing the pathological changes in this disease, Rivers writes as follows :—

> "If, as some believe, the Rous sarcoma appears to be more closely related to true neoplasms than to diseases induced by highly contagious agents, then the myxoma, upon further study, may serve to bridge the gap between the Rous tumor and other virus maladies, and to indicate that, after all, no great difference exists between tumor-forming viruses and those causing vesicular or destructive lesions."

Another disease which may further help to bridge the gap is the infectious fibroma lately described by Shope.[49] This, like the infectious wart, naturally occurs in wild cottontails and is transmissible also to laboratory rabbits. In the cottontail one finds subcutaneous fibroma-like lesions which only regress after many months. On injecting such material —or filtrates from it—into the testes or subcutaneous tissues of tame rabbits, Shope found that similar fibromatous lesions developed. They were white, rubbery in consistence, and histologically showed masses of spindle-shaped or polygonal cells, often in whorls; mitoses were scarce. Dr. Shope kindly sent me some of this virus and I have studied histologically the early changes produced by it in a rabbit testis and can confirm his findings; the primary lesion is a proliferation of the connective tissue cells, though some polymorphs are usually to be found also. Later the picture strongly recalls a spindle-celled sarcoma. There is, however, no metastasis to distant organs, and the fibromata always ultimately regress. The condition was unexpectedly found by Shope to be related to infectious myxomatosis, some cross-immunity between the two diseases being present; the fibroma-like condition differs greatly from the other, however, in that infection of one rabbit from another has not yet been demonstrated. I found no evidence of cross-immunity between the fibroma virus and a true tumour in a rabbit; rabbits in which the epithelial tumour of Brown and Pearce had regressed were normally susceptible to Shope's fibroma virus.

The interest of this virus does not end here. For apparently a mutation or adaptation of the virus can occur when it is passed through domestic rabbits. As a result of this change it no longer produces cell proliferation and tumour-like swellings but causes fever, necrosis at the site of inoculation, œdema, hyperæmia, and acute outpouring of inflammatory cells. More than this, inoculated rabbits may develop on the shaved skin generalised pock-like lesions recalling those of generalised vaccinia in the rabbit. I have recently had under study three strains of the virus: (*a*) is but a little way removed from the original cottontail tumour and produces fibroma-like lesions often of considerable size; (*b*) causes no primary proliferation of connective tissue cells but only acute inflammation accompanied by generalised pocks; (*c*) is a mixed strain which gives rise to nodules of fibroma-like growth in the midst of inflammatory lesions but never to big tumours; it also frequently produces skin-pocks. So far as I can determine I am not dealing with a mixture of two distinct viruses. The inflammation-producing strain completely immunises against the tumour-causing strain and vice versa. Neutralisation tests with immune sera confirm this result. We have apparently to deal with a virus which in two phases of activity can produce what is very like a tumour—or what is more like an eruptive fever. The interest of such a virus to the present argument needs no emphasis.

The next example in our series is Fujinami's[50] myxosarcoma as it affects well-grown ducks. Filtrates of this tumour, which was originally of fowl origin, injected into the leg of an adult duck produce tumours which grow very rapidly and may reach almost the size of a tennis-ball before they begin to regress[51] as, in the end, they always do. They only show local malignancy and do not metastasise. Histologically the picture is that of a myxosarcoma. Clearly the state of affairs is not very different from that of one phase of Shope's rabbit fibroma. The tumour is propagable by means of filtrates, but only if tumours from young ducklings are used as the source of material. In these young ducklings the picture differs chiefly in that the death of the bird often occurs; possibly this results from mechanical causes, the tumours being large relatively to the size of the host. If filtrates of this same sarcoma of Fujinami's are injected into a fowl the events are at first like those in the duck; a local sarcomatous tumour develops. But instead of regressing after a week or two it continues to grow and the bird almost invariably dies. Metastases occur, chiefly in the lungs, liver, and heart. The tumour is propagable indefinitely by means of cell-free filtrates; it is in fact in most respects identical with the Rous No. 1 sarcoma.

We may next turn to the Rous sarcoma when in the state, already mentioned, in which it grows poorly and cannot be filtered.[7] We may point out that during these phases its behaviour is like that of a non-filtrable mammalian sarcoma. The fowl endothelioma of Begg (Mill Hill 2)[52] is still more apt to defy all efforts at filtration for long periods.

A next stage is seen in the slow-growing fowl fibrosarcoma Mill Hill 1, also described by Begg. For

FIG. 1a FIG. 1b FIG. 1c

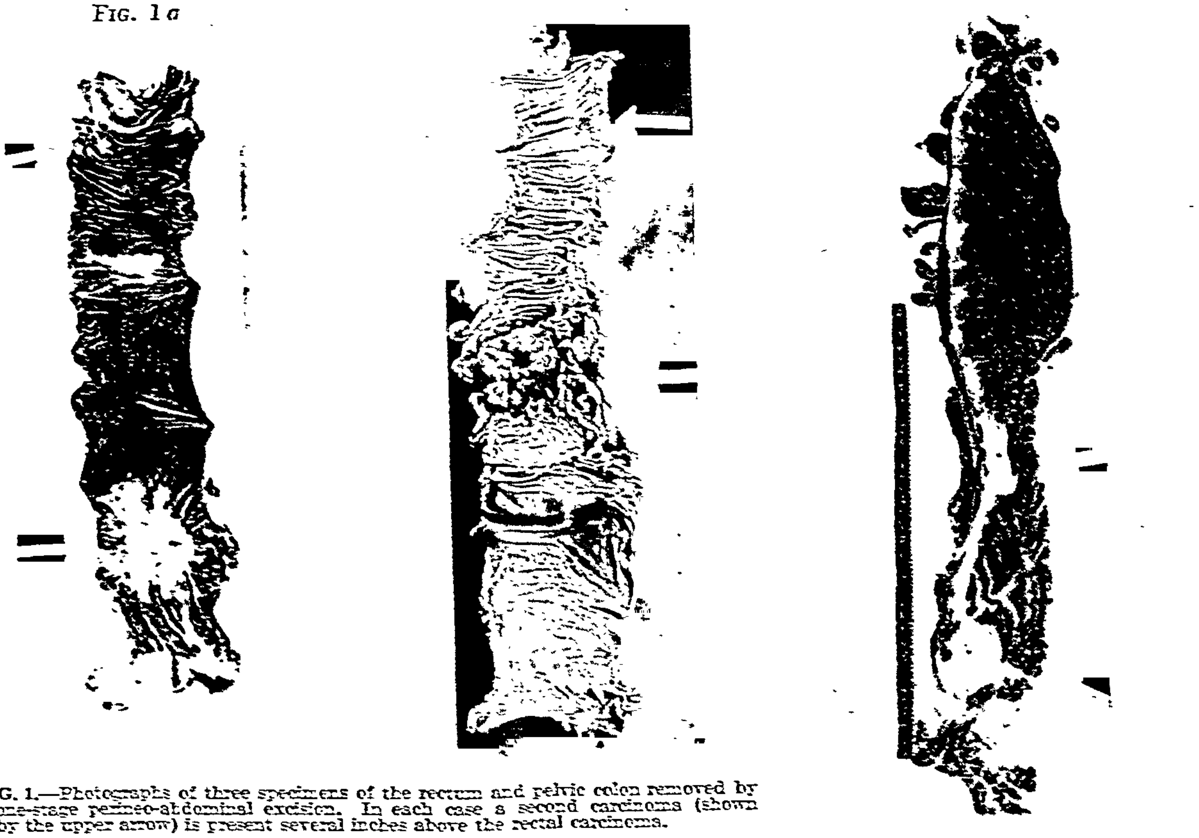

FIG. 1.—Photographs of three specimens of the rectum and pelvic colon removed by one-stage perineo-abdominal excision. In each case a second carcinoma (shown by the upper arrow) is present several inches above the rectal carcinoma.

(a) Specimen 18 inches in length from a male aged 62. An ulcerating growth, 2½ inches in diameter, extended almost completely round the middle third of the rectum; 9 inches above this growth there was a small indurated, pedunculated, and partly ulcerated tumour. Both tumours proved to be adenocarcinoma on section. Metastases present in the glands—C case.

(b) Specimen 18 inches in length from a male aged 77. A semi-ulcerated protuberant tumour almost completely encircled the upper part of the rectum; on section it was found to be an adenocarcinoma which had not extended into the extrarectal tissues. A pedunculated polyp 5 inches higher proved on section to be an adenoma which had undergone malignant change, with infiltration of the stroma. Glands free from metastases—A case.

(c) Specimen 21 inches in length from a male aged 66. Two ulcerating growths were present; one appeared as a flat ulcer 2 inches in diameter in the lower third of the rectum; the other, 1½ inches in diameter, completely surrounded the bowel in the rectosigmoid region. Both proved to be adenocarcinoma with involvement of the glands—C case.

to the colostomy. The presence of clear mucus on the perineal dressings is certain evidence of the development of a mucous fistula, which may in course of time close spontaneously; but it often persists, and is the cause of much continued annoyance from the discharge and recurrent perineal abscesses. A slight soiling of the wound no doubt takes place sometimes in the course of a perineal excision at the stage when the divided bowel is being inturned by suture. Occasionally serious sepsis occurs, and is, I believe, not uncommonly due to the presence of diverticulosis of the pelvic colon; diverticula contain highly infective material, and if they are pricked by a needle the consequences may be serious. I have lost one case of perineal excision from acute anaerobic wound infection with gas formation, which was undoubtedly due to this cause, and I now regard perineal excision as an operation of questionable merit in the short, thick-set subject, who has certainly a fat-laden pelvic colon, and possibly diverticulosis. Even if no gross sepsis occurs, the healing of perineal excision wounds often lags behind that of combined excision cases, and this is no doubt due to the presence of the sewn-over bowel stump, with a mild infection of the pelvic cellular tissues round it.

These various points form a very considerable argument in favour of a combined abdomino-perineal excision, provided a technique can be employed which will enable the operation to be done without a rigid exclusion, on the grounds of age or general condition, of that common type of rectal cancer case, particularly in males, who is classed as a "poor risk."

THE OPERATION RECOMMENDED

The merits of abdomino-perineal excision of the rectum by Miles's technique have been generally accepted, but the considerable number of two-stage modifications which have been described indicate the desire and the attempts of different surgeons to minimise the risks of the original operation. The chief risks of abdomino-perineal excision are sepsis and shock.

Sepsis may occur at the time of the intra-abdominal division of the pelvic colon, or during the time that the devascularised bowel is lying in the pelvis (pending the perineal removal), with a wide area of newly exposed pelvic cellular tissue round it.

Shock, most surgeons will agree, supervenes in the latter stages of the operation, particularly when the patient is turned over into the left or right lateral position, and during the final perineal excision.

The one-stage perineo-abdominal excision which will now be described is, I submit, an easier operation rectum without glandular metastasis or evidence of related adenomata above the growth. In such cases a perineal excision is as radical and as effective in curing the patient as an abdomino-perineal excision.

(2) Those late cases in which pre-operatively it is possible digitally to demonstrate extrarectal spread in the form of nodules or indurated lymphatics outside the rectal wall. These are advanced cases with marked lymphatic *spread, and if considered "operable" are certainly* ineradicable by the perineal route, and probably are equally ineradicable by a combined excision.

The early cancers low down in the rectum are rare, and it is problematical whether a surgeon, however experienced, can accurately forecast the presence and extent of extrarectal spread after a carcinoma has passed beyond the clinically early stage. In any average series of operable cases it is likely that approximately half will have glandular metastasis (Dukes[1] reports 47 per cent., McVay[2] reports 47 per cent.), and the following arguments favour a combined operation.

ADVANTAGES OF COMBINED OPERATIONS

1. *Situation of the primary growth.*—It is agreed by most authorities that the rectosigmoid is the common site for a carcinoma in this region. In a recent survey of 100 cases, Rankin, Bargen, and Buie[3] found that 69 were at the rectosigmoid juncture. This is in close agreement with the figure of 67 per cent. reported in 1903 by Tuttle,[4] and constitutes in itself a sound reason for carrying out a combined operation in at least two-thirds of the cases.

2. *Removal of the zone of upward lymphatic spread.*—Excision of the rectum by the combined route enables a ligature to be placed round the inferior mesenteric pedicle at an average height of 10 inches above the anus, which is at least 3 to 4 inches higher than the usual level of ligation effected in the course of perineal excision. In those cases in which extrarectal extension of the carcinoma has taken place with infection of the lymphatic glands (C cases by Dukes's classification), the extra few inches of the superior hæmorrhoidal pedicle gained by a combined excision may in some cases be the determining factor in eliminating the disease.

In a previous paper[5] I have reported that in C cases treated by perineal excision only 19 per cent. survived free from recurrence at the end of three years; this figure is almost identical with that reported by Rankin,[6] who shows 20·7 per cent. of good results after excision of the rectum in patients with proved metastases. It is now possible to state the results of the St. Mark's Hospital cases at five years; out of 20 C cases of perineal excision (operation survivals), operated upon prior to June, 1929, 15 have died from recurrence, 2 died from other causes, and only 3 have survived free from recurrence for five years—i.e., 16·6 per cent. ($\frac{3}{18} \times 100$). This result in a small series of cases expresses the failure by perineal excision to remove a sufficient length of the path of upward *lymphatic spread*, and in this respect there should be an expectation of achieving better results by a combined excision. At the present time, however, there is to the best of my belief no actual proof of the outstanding superiority of abdomino-perineal excision in C cases, and the following records suggest that in this late group a large proportion of cures cannot be expected. They summarise the results in 29 cases after survival from different types of combined abdomino-perineal excision.

(i) In 3 cases one-stage abdomino-perineal excisions were done more than five years ago. Of these 2 were A cases and have survived for nine and seven years respectively; 1 was a C case and died of recurrence two and a half years later.

(ii) In 4 cases two-stage abdomino-perineal excisions were done by Coffey's technique in 1929. Of these 2 were B cases and are now (June, 1934) alive and well; 2 were C cases and have died of recurrence.

(iii) In 1 case a two-stage abdomino-perineal excision using Dudley Smith's clamp was done in 1930. This was a C case and the patient died of recurrence 16 months later.

(iv) In 21 cases perineo-abdominal excisions were done between 1928 and 1933. There were 4 A cases and 6 B cases, who are all alive and well for varying times up to five and a half years. There were 11 C cases of whom 4 have died within three years after operation (2 recurred in liver, 1 had peritoneal secondaries, 1 secondary deposits in the brain). The remaining 7 are alive and well, the longest survival being nearly four and a half years.

It will be seen that in 29 cases the 8 bad results have been confined to proved C cases. The question of the eradication of the disease in such cases by a combined excision is one which we are actively investigating in St. Mark's Hospital. I believe there are grounds for saying that in the C group there will certainly be a number whose disease can be eradicated by a combined excision when a perineal excision would be inadequate.

3. *The length of bowel removed.*—By perineal excision the average length of bowel excised is not more than 9 inches; in many cases, owing to the difficulty in mobilising the rectum, the length is not more than 6 or 7 inches. By a combined operation such as the one now to be described an average length of bowel removed (anus to iliac colon) is 18 inches. The importance of this is in regard to the frequent incidence of adenomata above the main tumour, and to the not so rare occurrence of double malignant growths. During 1933 I had the unusual experience of finding double carcinomata in 3 out of 12 long specimens removed by perineo-abdominal excision. These are shown in Fig. 1; in each case the second tumour was not diagnosed before operation; it was found at a considerable distance, varying from 5 to 12 inches, above the rectal growth, and would certainly have not been removed by perineal excision. Examples such as these provide a good explanation of certain cases of intrapelvic "recurrence" after perineal excision.

4. *Difficulty of establishing a colostomy in continuity* ("*loop colostomy*").—A colostomy in continuity, which is a necessary preliminary to perineal excision, is occasionally a difficult or unsatisfactory procedure; in stout subjects or in those with a short pelvic mesocolon it may be impossible to bring a loop of pelvic or iliac colon to the surface without tension. There is subsequently a persistent tendency to colostomy retraction. The alternative of doing a transverse colostomy is not at all desirable in view of the long blind length of colon which remains after perineal excision. There is no doubt that in stout subjects the terminal colostomy which is left after a combined excision is both easier to establish and is more satisfactory subsequently; it cannot be affected, as is the loop colostomy, by "spur retraction."

5. *Other dangers or drawbacks of perineal excision.*—In subjects with a fat-laden pelvic colon it is often a difficult matter to effect a sound closure of the bowel in the course of a perineal excision; the formation of a mucous fistula into the perineal wound is a common and tiresome complication, which may be due, as mentioned above, to operative difficulties, or subsequently to the cutting out of the sutures closing the bowel; to poor healing capacity; or to the presence of fæcal masses in the pelvic colon distal

out. The pedicle is divided between the ligatures, and for additional security a second ligature is tied round the upper cut end of the vessels.

4. A left iliac muscle-splitting incision 4 inches in length is made, with some cutting across the fibres of the internal oblique. The iliac colon is brought out and the space lateral to the iliac colon is closed by a running atraumatic catgut suture. The rectum and pelvic colon are passed through this incision up to the stitch closing the lateral space. (Fig. 3.)

5. The pelvis is now empty and closure of the pelvic floor is a very easy matter, using a double No. 1 catgut stitch on a curved needle ; no mobilisation of the flaps is required as a rule, and a running suture is made extending back from the posterior aspect of the bladder or uterus, and eventually burying the ligature round the inferior mesenteric vessels. (Fig. 4.) The appendix is removed if it looks at all unhealthy, and the great omentum is pulled down. The paramedian incision is closed without drainage, and the left oblique incision is closed in layers round the emerging colon.

6. The pelvic mesocolon is now ligated about 1½ inches external to the skin, gauze dressings are applied, and the bowel is divided at the same level by a cautery in between clamps. The specimen of the rectum and pelvic colon is now removed, the division being in this way carried out as an extra-abdominal manœuvre. The crushed edges of the emerging colon are separated, and a No. 17 rubber catheter passed down and sutured in. Five ounces of warmed olive oil may with advantage be run through the tube with the object of being retained and lubricating the colonic mucous membrane; easier passage of flatus may in this way be promoted.

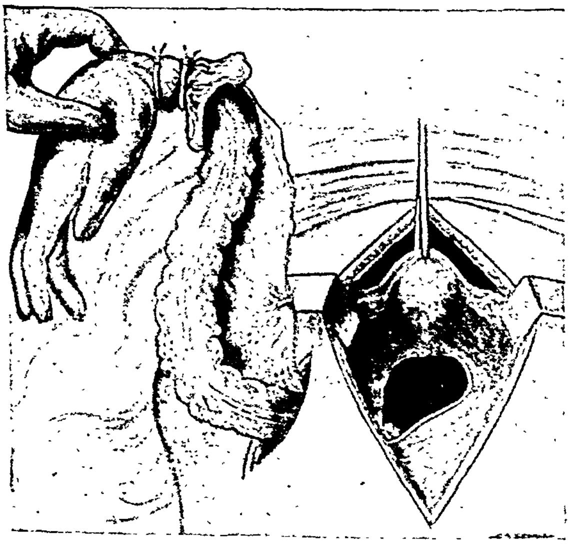

FIG. 3.—After ligation of the inferior mesenteric pedicle the mobilised rectum and pelvic colon are brought out of the abdomen through a left iliac incision. (Semidiagrammatic with omission of details of towels and packs.)

7. The median abdominal incision is sealed with gauze and Elastoplast. Finally the legs are held up by an assistant on each side, and the toilet of the perineal wound is completed ; the wound is swabbed dry and hæmostasis verified ; a sterilised yellow rubber bag (made for anæsthetic purposes by the Dunlop Rubber Company) is inserted and packed with gauze. The anterior third of the perineal wound is sutured and dressings are applied by lifting the patient and not by rolling him.

The only modification in the foregoing description which needs mentioning is that in 13 cases I have dispensed with the preliminary laparotomy and have done the operation as a "blind" one-stage perineo-abdominal excision. The cases selected for this have been those in which a clearly mobile and certainly operable carcinoma has been present, with the entire length of the tumour within reach of the finger. Although this method may be criticised on the score of possible liver secondaries being present, I do not believe it to be a valid objection. The passing of a hand over the surface of a liver and finding it smooth does not by any means exclude the presence of central secondary deposits, and if the operator has experience in assessing operability, I believe the blind operation is valuable—it saves both time and a turn. I have not yet found my pre-operative estimate belied by local fixity, or peritoneal or liver secondaries. I should not on any account advise this blind operation for a high constricting or deeply ulcerated carcinoma ; in these cases abdominal exploration is imperative.

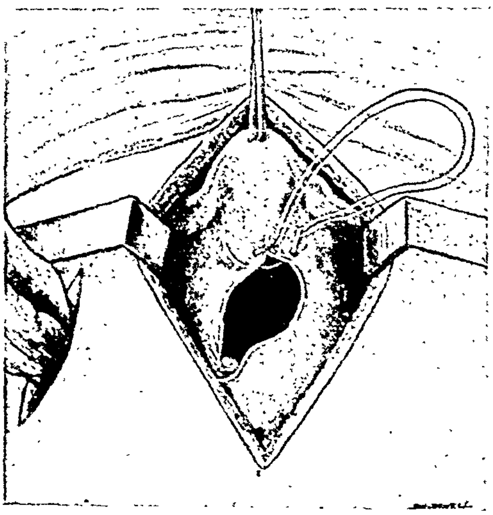

FIG. 4.—Closure of the pelvic peritoneum.

In view of the risk of sepsis in the abdominal wall I have abandoned perineo-abdominal excision as a second stage after a preliminary colostomy operation. In most cases, by suitable preparation, the bowel can be rendered empty and fit for a one-stage operation. If in the case of a constricting carcinoma in the recto-sigmoid region a preliminary drainage operation seems imperative, a cæcostomy would appear to be preferable. I have done this in a recent case, followed by perineo-abdominal excision, with a very satisfactory result.

Subsequent treatment.—The foot of the bed is raised on medium blocks for 24 to 48 hours. An intravenous injection of saline with 5 per cent. glucose (20–30 oz.) is given after operation, and may with advantage be repeated daily for the next two or three days. The gauze packing is removed from the perineal bag on the second post-operative day, and the bag itself is taken out on the next day. The perineal wound is then irrigated and dressed with eusol morning and evening, and usually heals very quickly. The sutures are removed from the perineal wound on the sixth or seventh day. There are no other details of any importance to record ; the post-operative course has usually been singularly smooth and free from anxiety.

to perform provided the operator has the experience which enables him to do a neat perineal dissection; it overcomes the serious difficulties of a narrow male pelvis, especially in those cases with a large tumour at the rectosigmoid junction; the dangers of sepsis and shock are largely eliminated—the former by avoiding intraperitoneal section of the colon, and shock by doing the perineal part of the operation first, so that no turning of the patient is required after completion of the abdominal operation. It fulfils all the requirements of a radical operation in regard to high section of the vascular and lymphatic pedicle; in regard to the length of bowel removed, I believe it is slightly more radical than Miles's operation, for the entire length of the rectum and pelvic colon up to the left iliac colostomy is removed.

In many of the classical operations of a radical nature, such as gastrectomy, nephrectomy, ovariotomy, it is an accepted principle to mobilise the part to be removed, and then to use it as a steadying agent by which a little traction may be applied, if required, until the vascular pedicle has been secured by transfixion and ligation, whether by use of an aneurysm needle or other form of ligature carrier. This principle is employed in perineo-abdominal excision and enables the operator to ligate the inferior mesenteric artery between the first and second sigmoid branches, which will free the entire pelvic colon for removal.

Preparation of the patient.—It is advisable that the patient should rest in bed for 7 to 10 days before operation, and much has to be done in this time.

(1) His cardiac condition and blood pressure will be estimated, and if necessary small doses of digitalin, such as Nativelle gr. 1/600 twice daily, may be indicated. (2) The urine excretion and blood-urea will be measured, and forced intake of fluids by the mouth will be encouraged. (3) Glucose in the form of barley sugar or glucose with lemonade or barley water will be given daily. (4) Smoking will be restricted and deep breathing encouraged. Dental sepsis will be attended to. (5) The diet will be of a non-residue nature, and the bowels will be cleared by aperients. Mag. sulph. may be given on two or three days in the amount of 1 drachm in water hourly for three or four doses; this will render the motions fluid and should eliminate any fæcal impaction above the growth. A simple enema is given on the night before operation, and a rectal tube is passed on the morning of operation. It is important that no free fluid should be present in the rectum at the time of operation. (6) In order to promote and maintain bowel tone, 0·5 c.cm. of Pitressin is given hypodermically one hour before operation, and is continued at four-hourly intervals for the first two or three days after operation.

Anæsthesia.—Although a few of these operations have been done under spinal anæsthesia, it is my firm conviction that my patients have done better under general anæsthesia, with novocain infiltration of the rectus muscles, than they have under spinal anæsthesia, or a combination of spinal and general anæsthesia. The operation as I do it takes two hours to complete, and a number of very frail patients have come safely through the operation under straightforward general anæsthesia (gas and ether, open ether, and in the latter stages, gas and oxygen), when I am sure that spinal anæsthesia would have been dangerous or even fatal. There have been two deaths on the table in stout subjects who had received a spinal injection; supplementary general anæsthesia was required while they were in the Trendelenburg position, and death took place imperceptibly, probably from a combination of lowered blood pressure with respiratory and cardiac failure. I feel sure that with general anæsthesia alone no difficulty would have been experienced. Quite a number of these cases have had a pulse-rate of 100 or more at the beginning of the operation, and at the conclusion two hours later, after general anæsthesia alone, the rate has slowed to 84–96.

Operative technique.—The operation of perineo-abdominal excision in one stage is carried out in the following distinct steps:—

1. For tumours in the upper third of the rectum, and for all tumours in the advanced or borderline category, an abdominal exploration is done through a right paramedian subumbilical incision. The liver, great omentum, and pelvis are examined in turn, and the operability of the growth confirmed before proceeding. The wound is closed temporarily by through-and-through silkworm gut sutures with an anchored gauze dressing.

2. *The patient is turned into the left lateral position,* the anus is firmly closed by two purse-string sutures of stout silk, and the perineal excision is proceeded with in the usual manner, *after disarticulation of the coccyx.* Before opening the peritoneum the anus and rectum are enveloped *in wet flavine gauze,* and a sterile glove is tied firmly over. After opening the peritoneum straight scissors are used to incise the peritoneum upwards on each side of the colon (about ½ in. distant), *for as far as possible.* (Fig. 2.) The rectum is mobilised laterally and posteriorly without encroaching on the superior hæmorrhoidal vessels, and is then pushed up into the pelvis. The posterior third of the perineal wound is sutured, a clean flavine pack is tucked into the remainder of the wound, and a sterile towel covers it. The patient is turned on to his back.

3. Trendelenburg position. The abdominal wound is reopened and small intestines packed out of the pelvis. The glove covering the rectum will now be seen and, as a rule, even in a narrow male pelvis, the rectum will be *readily delivered upwards.* The lateral incisions are continued upwards and with little difficulty the rectum and pelvic colon are stripped up till they are delivered freely out of the abdominal wound. The inferior mesenteric pedicle is now clearly defined by traction on the bowel, and the optimum point for application of a double silk ligature is made

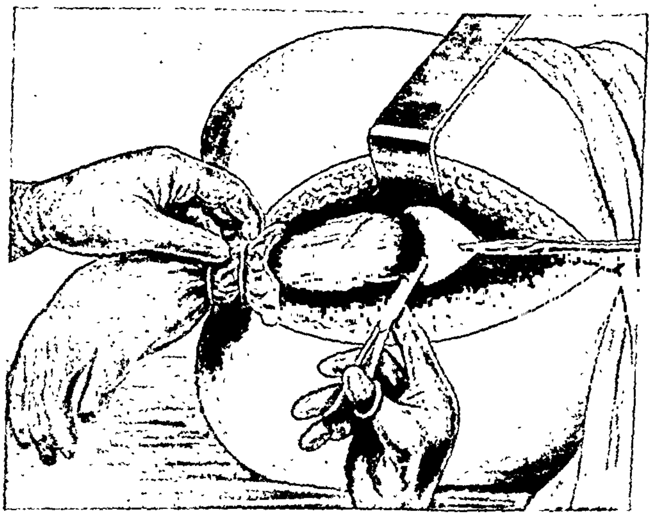

FIG. 2.—The perineal stage. The rectum is wrapped in a sterile glove and the peritoneum has been opened. The peritoneum is being incised upwards on each side for as far as possible.

a case by simple puncture after which the cyst disappeared and regular menstruation continued.

Lockyer mentions a case which developed a tense cystic swelling six months after operation in 1920. This proved to be a blood cyst. It was opened and scraped. Five months later another small cyst developed, but as it caused no inconvenience it was left alone. He has since carefully removed the cortex of the ovary before cutting grafts.

Blair Bell in a personal communication to Lack quotes two cases of cyst removal on account of metrorrhagia which ceased after their removal. The cysts were probably follicular and not lutein in origin.

Lack gives details of a case of excision of cysts five months after operation. There were two cystic cavities in a dense mass of fibrous tissue, one with a yellow lining. Pathological report: "Follicular cysts; one showing changes suggesting a modified lutein reaction."

Mayer: Case of engrafting in November, 1926. Periods commenced in January, 1927. A painful swelling developed in March, 1927, due to a cyst. It was punctured with good results till May, when it refilled. A second puncture proved unsuccessful, so in July the cystic graft was removed with relief of the abdominal pain but onset of climacteric.

Heynemann is quoted by Mayer. He states that he has been compelled to remove grafts on account of painful swelling. On removal, follicular and blood cysts were found. Details of cases are not given.

King: This case, which occurred in Australia in 1932, includes a detailed pathological report of several blood cysts occurring in a case where, I gather, the whole right ovary was transplanted, with its corpus luteum. Menstruation recurred normally, but a year after operation periodic pain and swelling of the graft necessitated its removal. Examination showed two large cysts and several smaller ones filled with chocolate-coloured material and altered blood. They are described as atretic follicles with one cyst containing degenerated luteal tissue.

DISCUSSION

In reviewing what has been written on this subject one is struck by the waning enthusiasm of the experts for homogeneous ovarian transplantation. The reports previous to 1917 are nearly wholly favourable, and praise the immediate and remote effects of autotransplantation (vide Lydston, Newton, Norton, and Phillips). Even Benthin is favourably impressed with the results, although most German authors, except Unterberger, seem to have had a good deal of trouble with their cases. Siegert in 1929, for instance, analyses nine cases as follows: in 5 no period occurred between six months and a year after operation; in 2 irregular losses occurred for a short time; and in 2 regular periods occurred after some months. In one case only was the result really satisfactory. In this patient the periods recommenced after five months.

After 1917 the American and German records become more despondent. Martin, who gives excerpts from most of the previous writers, and Graves comment on the failure of grafting in cases of total ablation of the uterus and appendages. The latter author even gives the opinion that retention of ovarian tissue after hysterectomy may be productive of serious harm to the patient. It is certainly of interest that the enthusiasts, mostly American, published their results within a year of implanting the grafts. Sippel, whose publications are too numerous to quote, denies the efficacy of ovarian grafts in preventing ablation symptoms. He finds that intraperitoneal grafts frequently cause metrorrhagia and are often productive of abscesses and cysts. This habit of intraperitoneal grafts to become cystic is confirmed by most authors and makes it seem still more curious that so few extraperitoneal cysts are recorded.

The consensus of opinion at the moment seems to be that grafts should not be implanted to prevent ablation changes, which rather limits their field of utility, but that they may occasionally benefit a case where the uterus has not been removed. There is quite a chorus of approval for grafting in cases of hypogenitalism and eugenic sterilisation, particularly from Lydston (quoted by Martin), who records successful heterogeneous grafts taken from the dead body *any time before decomposition set in!* (The italics and exclamation mark are mine.)

Recent work on autogenous grafts suggests that the pendulum is again swinging towards a favourable view. The latest European report of Cheval and Mayer is almost wholly favourable even in cases of total and subtotal hysterectomy. They state that the only portion of the graft which persists and develops is the superficial layer containing the germinative epithelium and primordial follicles, the centre merely necroses; thick grafts are therefore useless and peeling of the surface is inadvisable. The superficial layers should be preserved and handled carefully. Two or three grafts are placed either in the superficial part of the right rectus muscle under the aponeurosis or in the subcutaneous cellular tissue (preferably in the submammary furrow). Uterine grafts are also advocated. These are cut from the removed uterus after swabbing it with 5 per cent. iodine and dividing it into anterior and posterior halves. They should include the mucosa, submucosa, and a small portion of the muscle.

An analysis of the results of 32 cases gives the satisfactory report of "endocrine troubles were absent and menstruation conserved" in 70 per cent. It is further stated that for three months after the operation patients still suffer from all the troubles of the menopause; these attenuate and disappear when menstruation is re-established, which rarely occurs before the fourth and usually at the eighth month.

In the recorded cases of cystic changes in grafts, much discussion has occurred about the nature of the cysts. With two exceptions they all seem to have been simple follicular cysts containing straw-coloured fluid; the others contained blood and sometimes showed lutein changes. Without entering pathological territory I should like to suggest a possible common origin for all these cysts. In a normal ovary the Graafian follicle ruptures into the peritoneal cavity and discharges an ovum and a variable quantity of blood, sometimes sufficient to suggest a diagnosis of ruptured ectopic gestation. This is usually, except in extreme cases, easily absorbed by the peritoneum. The extraperitoneal graft has no convenient peritoneal cavity for this purpose, and the ova and products of the corpora lutea are presumably scattered about in the fascia and absorbed. Should absorption fail to occur a hæmatoma with a partial epithelial lining would be left. Subsequent degeneration of the granulosa cells and serum exudation would produce small cysts of a similar character to those described.

Some authorities advocate stripping the ovarian cortex before taking grafts as a method of preventing cyst formation. This would, of course, remove the germinal epithelium (Cameron), but it is difficult to see how it would prevent cystic degeneration unless these described are really multilocular cysts of cortical origin. If so, it may strengthen the theory of their development from the so-called "egg tubes" of Pflüger on which a certain discredit has been cast by former writers. If, however, Cheval and Mayer are to be believed, such decorticated grafts would

IMMEDIATE RESULTS

Since January, 1932, I have done this operation in one stage on 25 occasions (12 with preliminary laparotomy and 13 without). Three patients have been 70 or over and have recovered; the oldest was a man aged 77 who made an uninterrupted recovery after the operation. Two other notable recoveries have been the case of a stout woman of 40 who weighed 13 st.; and a minute little woman (70 years) who was only 4 ft. 8 in. high, and weighed 5 st. 11 lb. In 25 cases there have been 5 operative deaths; 2 deaths on the table which were due, I think, to an exceptional combination of circumstances; 1 death on the fourth day (male aged 69) was clearly due to cardiac failure with auricular fibrillation; and 2 occurred on the seventh day from a combination of small intestinal ileus and bronchitis; this happened before I had begun the prophylactic injections of pitressin.

The justification for the operation in these cases is that microscopical proof of metastases in the glands along the line of upward lymphatic spread has been obtained in 14 out of the 25 cases (56 per cent.). I am now restricting perineal excision to those cases of carcinoma of the anal canal or lower third of the rectum when the tumours are either very early, or so late that by reason of involvement of the vagina, prostate, or ischiorectal fossa, the extra risks of a combined excision do not appear to be justified.

CYST FORMATION IN OVARIAN GRAFTS

WITH REPORT OF A CASE

BY JAMES S. HALL, M.B. Lond., F.R.C.S. Edin.
HON. SURGEON TO THE VICTORIA HOSPITAL, DEAL

THE recorded cases of cyst development in extraperitoneal ovarian grafts are curiously few in number. Lack in 1924 was only able to find 2 cases specifically mentioned in the literature, one by Graves, who performed three operations for subsequent changes in a bilateral graft, the other by Blair Bell, who had 2 cases in a series of 150 grafts, the second of which, I believe, is still unpublished. A further case was reported by Lockyer after the above paper, making a total of 5 in all.

I was able, after a careful search, to augment this list by 2 cases quoted in some detail by Mayer. The first is probably the earliest recorded (Columbino, 1914), the second by Unterberger in 1919. This case is especially interesting because a cure followed simple puncture; most of the other cysts have given much more trouble. Since 1924 there appear to be three more case records. Here is the chronological table to date:

Columbino ..	1914	Lack	1923
Graves ..	*1915*	Mayer	1927
Unterberger ..	1919	Heynemann ..	1930
Lockyer ..	1920	King	1932
Blair Bell * ..	1920		

* Two cases.

The following case of my own in 1933, to the best of my knowledge, completes the list.

NOTES OF CASE

A married woman of 23 with one child aged 2 years, was admitted to the Victoria Hospital, Deal, in 1929. She complained of abdominal pain chiefly localised in the left iliac fossa of several months' duration with exacerbation of the pain at the periods. Examination showed enlarged and tender tubes which at the subsequent operation were found inflamed and adherent. The left ovary was involved in the inflamed mass and contained several cysts. Both tubes and this ovary were removed, the right ovary, which appeared normal, being left. The appendix had been removed several years before. Convalescence was uneventful, the patient leaving hospital *healed and free from pain.*

She consulted me again in November, 1931, with dysmenorrhœa and fairly severe abdominal pain, this time chiefly confined to the right iliac fossa and of the same type as her left-sided pain of two years before. In spite of various treatment she became worse and I readmitted her to hospital in July, 1932, for further operative treatment. As this almost certainly involved removal of the second ovary it was done with great reluctance, in view of the fact that the patient was a thin and extremely nervous type, quite the last case one would choose for an artificial menopause.

At operation the remaining ovary was found enlarged and cystic. The uterus showed nothing abnormal and was left alone, the ovary being cleanly removed. A section of the healthiest end was taken, about the size and shape of a shilling, and embedded between the left rectus muscle and the posterior sheath. An uneventful recovery followed, the patient leaving hospital a fortnight later. Her subsequent history is as follows: Periods (previously of 5/28 type) recommenced three months after operation, and were of a 5-14/28 type. The loss was not excessive even in a prolonged period, and no pain was felt in the region of the graft although some tenderness and enlargement occurred at these times.

In December, 1932, flooding commenced and periods became more regular and of a 10/28 type with one curious exception. A hot-water bottle applied to the now definite swelling in the left rectus muscle always produced a "period" the next day. Pressure or injury to the abdominal wall had no such effect.

In October, 1933, she again sought admission to hospital for relief of excessive flooding and a very painful and tender swelling about the size of a hen's egg in the region of the graft. She volunteered the information about the curious effect of the hot-water bottle applications, and stated that the pain was exactly similar to her previous ovarian pain but much more superficial. Pressure on the lump made her feel sick. An experimental application of the hot-water bottle produced a "period." During this a small incision was made under Evipan anæsthesia and the swelling found to be a bilocular cyst filled with clear straw-coloured fluid, the two parts being about 1 in. and ½ in. respectively in diameter. Small pieces of the cyst wall were removed for microscopy. Subsequent pathological report confirmed these to be normal ovarian tissue.

The patient is now free from pain again and has had a normal but scanty period (December, 1933) without pain in the uterus or site of graft. She is still thin and nervous, but otherwise in good health.

PREVIOUS CASES

The previous cases may be briefly summarised:—

Columbino in 1914 was forced to remove an extraperitoneal graft because local disturbances occurred. Corpora lutea were present and three-quarters of the whole graft was cystic.

Graves removed cystic ovarian tissue in *1914 from fat* on the left side of an abdominal incision. A *bilateral graft had been done six months before.* A month later he removed similar tissue from the right side and eighteen months later removed still more cystic material from the left side.

Unterberger records a case in 1919 in which he treated

TABLE I

SHOWING THE MAXIMAL FINDINGS OBSERVED IN FRACTIONAL TEST-MEALS AFTER FEEDS OF RAW AND BOILED MILK

Case.	Sex.	Age in mos.	Free HCl.		T. acidity.		T. chlorine.		Peptic acidity.		pH.		Curd.

R. = raw milk; B. = boiled milk; T. = total.

RATE OF EMPTYING

The amount of curd varied considerably, but in 9 cases it was more abundant with boiled milk and in 7 with raw milk. In 1 it was about equal in amount with both types of milk. In 13 tests with raw and 14 with boiled milk there was obvious curd at the end of two hours, while in 4 with raw and 3 with boiled milk the two-hourly specimens were free of curd. In the majority of cases, therefore, the stomach was over two hours in emptying with both types of milk, which confirms the findings of Wills and Paterson,[5] who state that the stomach empties in two and a half hours in artificially fed infants.

PEPTIC ACTIVITY

The maximum peptic activity was higher with raw milk in 13 cases and with boiled milk in 4 cases, but there was a wide variation between the values in each ranging from 6·4 to 78·4 for raw milk with a standard deviation of 20·6, and from 3·6 to 78·4 for boiled milk with a standard deviation of 18·3. The average maximum for raw milk was 32·6 and for boiled milk 24·2. In view of the wide dispersion the difference between the averages cannot be considered significant.

SOLUBLE CALCIUM

The soluble calcium was estimated in 13 cases. It was low in the fasting juice and generally rose to a maximum within the first hour. In some cases there was a fall before the end of the second hour, while in others the value still remained high. With raw milk 4 showed the fall at two hours, while with boiled milk this was observed in 4 cases. In all, excluding the fasting specimens, 47 pairs of samples with raw and boiled milk were examined, and of these 30 showed a higher value with boiled and 17 with raw milk. The average of the maximal figures for raw milk was 52·4, and for boiled 62·0, which suggests that the calcium is better held in solution when boiled milk is used. But the maximal figures for raw milk ranged from 33·3 to 80·3 with a standard deviation of 12·5, and from 27·3 to 91·4 with a standard deviation of 18·1 for boiled milk; hence little importance can be attached to this difference in the averages.

TABLE II

SHOWING CHANGE IN SOLUBLE CALCIUM IN FILTERED GASTRIC CONTENTS AT HALF-HOURLY INTERVALS AFTER FEEDS OF BOILED AND RAW MILK

Case.	Sex.	Milk.	Calcium mg. per 100 c.cm.

9	M.	R.	46·7	66·6	71·4	71·4	71·4
		B.	46·7	43·6	90·9	181·8	181·8

NON-PROTEIN NITROGEN

The amount of non-protein nitrogen was very constant in the fasting juice of each of the six cases examined. In four the values for raw and boiled milk were very close inevitably die and therefore cyst development would be aborted.

Should cysts occur in a graft removal appears to be the best treatment; in one case only has a cure followed simple puncture. All authorities agree that extraperitoneal implantation is simple and free from danger in selected cases, also that no recorded changes of a malignant character have yet occurred.

I should, in conclusion, like to thank Mr. T. J. Shields, the librarian to the British Medical Association, for his very considerable assistance with the references.

GASTRIC DIGESTION OF RAW AND BOILED MILK IN INFANTS

BY JESSIE W. OGILVIE, B.Sc., M.B. Glasg., D.P.H.

AND

OLIVE D. PEDEN, B.Sc.

(From the Department of Pædiatrics, Glasgow University, and the Biochemical Laboratory, Royal Hospital for Sick Children, Glasgow)

THERE is still much discussion on the relative digestibility of boiled and unboiled cow's milk. Graham and Morris [1] found that in infants the protein, fat, and minerals of boiled and unboiled milk were equally well absorbed. M. Andross [2] concluded from in-vitro experiments that pasteurisation, and to a greater extent boiling, renders the protein of milk less readily digested by pepsin and trypsin. Stirling and Blackwood,[3] in their comprehensive monograph, reviewed the results of previous experiments on the digestion of boiled and unboiled milk, and state that these results were very conflicting. At any rate, the results of in-vitro experiments must be applied with caution to the course of digestion in the living subject where the conditions are clearly different, for in these the amount and composition of the gastric secretion may be altered in response to different types of food.

From the practical point of view, therefore, it seemed advisable to study on the infant the effect of boiling on the gastric digestion of milk. For this purpose the gastric contents were removed before and at half-hourly intervals after test-feeds of raw and boiled milk. The following were used as indices of the course of digestion.

(1) The amount of free hydrochloric acid and total chlorine, and the degree of total acidity. This was done since the reaction of the gastric juice is of considerable importance in the digestion of proteins and the utilisation of minerals.

(2) Peptic activity, to determine whether any change in the physico-chemical composition of the milk alters the secretory activity of the zymogen glands.

(3) Soluble non-protein nitrogen as an index of the extent to which proteins are disintegrated.

(4) Soluble calcium as an indication of the capacity of the gastric secretion to convert minerals into a soluble and therefore a readily assimilable form.

The last two were specially chosen because of the frequently reiterated claims [3 4] that the main drawback of boiled milk is that changes occur in the nature of its calcium and nitrogenous constituents, rendering them less susceptible to the action of gastric juice.

Fractional test-meals after raw and boiled milk were carried out on 17 infants whose ages ranged from 3 to 23 months, and who had recovered from the various diseases for which they had been admitted to hospital and who appeared healthy at the time when the tests were performed. The test-feeds consisted of boiled or raw milk in amounts varying with the age of the subject; the gastric contents were examined before and at half-hourly intervals for two hours after the feed.

The amount of curd was noted in each specimen which was then filtered through glass wool. The free hydrochloric acid, total acidity, and total chlorine of the filtrate were estimated by the usual methods, and the pH of each specimen determined by means of the B.D.H. capillator. A measure of the peptic activity was obtained by the Mett's tube method; the amount of egg-white digested after incubation for 24 hours was measured in millimetres, and the figure obtained taken as an index of peptic activity. The proteins were removed by the addition of 9 c.cm. of 15 per cent. trichloracetic acid to 1 c.cm. of filtered gastric contents. The precipitate was filtered off and the filtrate used for determining the non-protein nitrogen by the micro-Kjeldahl method. The soluble calcium was estimated by a modification of Kramer and Tisdall's method. The results are given in detail in the Tables.

ACIDITY

The pH varied between 6·8 and 4·6 in the absence of free acid, but was as low as 2·1 when free hydrochloric acid was present. The difference (0·28) between the average maximum for raw and boiled milk (3·99 and 3·71 respectively) was not significant. Wills and Paterson [5] state that the average pH for normal infants on cow's milk is 3·5, but they do not state whether the milk was boiled or not.

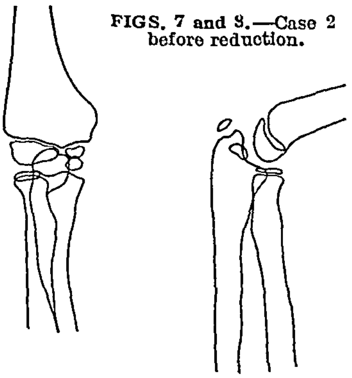
No free hydrochloric acid was found in either test in 8 cases (47 per cent.), while in 4 the maximum was higher with raw milk, in 3 with boiled milk, and in 2 it was the same in both. The average maximum figure was higher with raw milk, being 5·9 c.cm. N/10 NaOH for raw and 4·6 c.cm. N/10 NaOH for boiled, but the difference (1·3) was too small to be significant. There was very little difference in the maximal total chlorine of the gastric contents with raw and boiled milk. Actually there was only a difference of 0·5 milli-equivalents per litre between the average maxima.

The percentage maximum total acidity for raw milk varied from 25·0 to 66·7 c.cm. N/10 NaOH with a standard deviation of 4·3, and for boiled milk from 37·8 to 80 c.cm. N/10 NaOH, with a standard deviation of 3·8. In 10 cases the maximum was higher with boiled and in 7 with raw milk. The average maxima were 50·4 for raw and 53·4 for boiled milk; the difference, 3·0, however, was not found to be statistically significant.

It is obvious that there is no significant difference in the behaviour of either free hydrochloric acid or total acidity of the gastric juice with raw and boiled milks.

I decided to attempt manipulative reduction before resorting to open operation. Under nitrous oxide anæsthesia the forearm was strongly abducted at the elbow so as to open the inner side of the joint. This released the "sandwiching" of the epicondyle, and during flexion and extension movements of the elbow the epicondyle was felt to slip out of the joint. If the forearm is kept supinated and the fingers are extended, tension is exerted on the common flexor origin and this may aid reduction. Fig. 5 is a tracing of a radiogram taken with the elbow flexed after reduction. This shows good apposition of the epicondyle to the humerus and it is lying in its normal position.

The elbow was immobilised in flexion for three weeks, and after this movements of the elbow were allowed to return naturally without any special treatment. Commencing recovery of the ulnar nerve lesion was noted on Sept. 7th, and the elbow movements on this occasion were full in flexion and radio-ulnar movements, and extension was possible to 180°. The final condition (Jan. 4th, 1934) was as follows: ulnar nerve lesion completely recovered; elbow movements, flexion, and radio-ulnar movements normal; extension 180° (normal side 190°); no symptoms. Radiogram (Fig. 6) shows fibrous union with displacement of the epicondyle downwards from its normal position. This is a common sequel of fractures and epiphyseal separations of the epicondyles and has not prejudiced function in this case. It is possible that extension movements of the elbow were allowed too early in this case and consequently union of the epicondyle prevented.

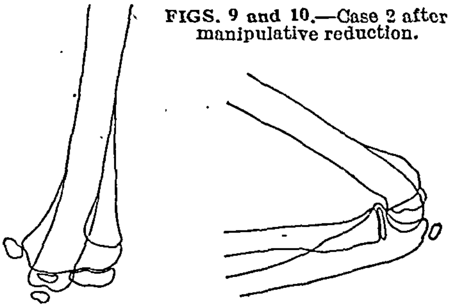


FIGS. 7 and 8.—Case 2 before reduction.

Case 2.—A boy, aged 10, was seen by me on Dec. 16th, 1933, having fallen two days previously and injured his left elbow. There was considerable swelling round the elbow and tenderness localised over the internal aspect of the lower end of the humerus. There was no circulatory disturbance but a definite ulnar nerve lesion was present. X rays (Figs. 7 and 8) show displacement of the internal epicondyle into the joint, the appearances being almost identical with those of Case 1. I manipulated the elbow in the same manner as in Case 1 and during manipulation the epicondyle was felt to slip out of the joint. X rays (Figs. 9 and 10) show reduction of the displacement. The epicondyle is lying slightly higher up the shaft of the humerus than its normal position. This case is still under treatment. There is limitation of the last 20° of extension and a partial ulnar nerve lesion persists. An anterior transposition of the ulnar nerve will be necessary if the nerve lesion does not recover completely in the next month or two.

Case 3.—On searching the records of the Liverpool Royal Infirmary for fracture cases for the last seven years I was able to find twelve other cases of displacement of the internal epicondyle into the elbow-joint. With one exception these had all been treated by open reduction of the displacement, and in most cases an anterior transposition of the ulnar nerve. One case, however, had been successfully reduced by manipulation. This case belongs to the first category described above in which a gross outward dislocation of the elbow is present. Figs. 1 and 2 illustrate the appearances in this case. Mr. A. L. Kerr saw the patient on Sept. 11th, 1928, and the displacement of the epicondyle was reduced by manipulation only. The ulnar palsy recovered completely in three months, and the final condition was: good function in the elbow with 15° of limitation of full extension.

Case 4.—A man, aged 22, fell off his horse while riding on Dec. 2nd, 1933, and was seen by Mr. R. Watson Jones the same day. There was an outward and backward dislocation of the elbow present and the internal epicondyle had been avulsed and was lying below the trochlear surface of the humerus. The dislocation was reduced by Mr. Watson Jones by manipulation and the epicondylar fragment restored to its normal position. There was no nerve lesion in this case. With a view to preventing fibrous union of the epicondylar fragment, the patient was operated on on Dec. 19th and the epicondyle sutured accurately into position.



FIGS. 9 and 10.—Case 2 after manipulative reduction.

SUMMARY

(1) Four cases are described in which displacement of the internal epicondyle into the joint has been reduced by manipulative measures alone. (2) There is no reason to suppose that recovery of the ulnar nerve lesion or the ultimate function of the elbow will be prejudiced by this line of treatment. (3) Stress is laid on the importance during manipulation of opening the inner side of the joint so as to allow the internal epicondyle to retrace its original displacement. (4) In the absence of operative treatment there is the possibility of fibrous union of the epicondyle occurring but this is of no importance. (Fibrous union of the epicondyle also occurred in two cases which had been submitted to open operation and in which the epicondyle had been sutured in its correct position.) (5) It appears likely that attempted manipulative reduction will be successful in a high proportion of cases seen within the first few days, and the necessity for open operation avoided, with consequent shortening of convalescence and avoidance of any possible complications.

I am indebted to Mr. Watson Jones for the notes of the fourth case in this series and for his kind permission to publish the other three cases.

Middlesex Hospital.—The annual report records that 7987 patients were admitted last year, whose average weekly cost was £4 13*s*. 4*d*. Their average stay was 20·38 days, and their total cost £13 11*s*. 9*d*. Out-patients numbered 47,995, and their 264,911 attendances were a large increase. They cost 9*s*. 7·94*d*. each. The year closed with a surplus of £3512, which is accounted for by the unusual sum received from legacies. Dr. W. Essex Wynter, consulting physician to the hospital, has rounded off his gift of Bartholomew Manor, Newbury, as a home for retired Middlesex Hospital sisters and nurses, by the purchase of two more ancient cottages which he has restored and put into use. Eleven former sisters and nurses now have their homes there, and others are shortly to join them.

at each half-hour period. In the other two the values for boiled milk were greater, showing that its protein had been more rapidly digested than that of raw milk.

Of the 24 pairs of half-hourly samples for raw and boiled milk half showed higher values with boiled and half with raw milk, so that there is no evidence of better gastric digestion of the protein of raw milk than of boiled milk.

It is clear from these results that there is no significant difference in the gastric digestion of boiled and raw milk, and it may be concluded that digestion of milk is not adversely affected by boiling.

We desire to thank Prof. G. B. Fleming and Dr. N. Morris for suggesting this investigation and for their helpful criticism. The work of one of us (J. W. O.) was done during the tenure of a McCunn medical research scholarship.

DISPLACEMENT OF THE INTERNAL EPICONDYLE INTO THE ELBOW-JOINT

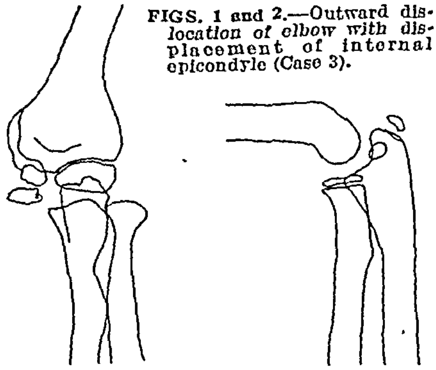
FOUR CASES SUCCESSFULLY TREATED BY MANIPULATION

BY NORMAN W. ROBERTS, M.B. Lond. & Liverp., F.R.C.S. Eng.

ORTHOPÆDIC REGISTRAR, LIVERPOOL ROYAL INFIRMARY

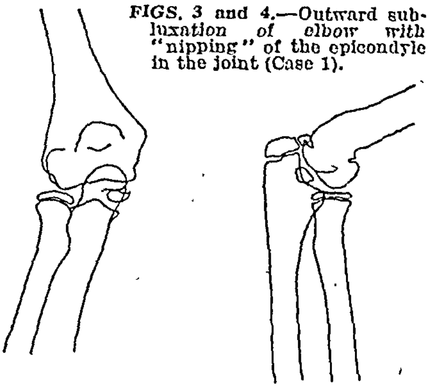
THE following cases are recorded in order to draw attention to the possibility of successful manipulative reduction of displacement of the internal epicondyle into the elbow-joint. This condition is not very common but probably is not as rare as is supposed.

A simple separation of the internal epicondyle without dislocation of the elbow is a common injury in childhood and is due to indirect violence acting through the common flexor origin and other soft tissues on the inner side of the elbow. If the violence is more severe a pure outward dislocation of the elbow or a combined outward and backward dislocation results. The former always results in an ulnar nerve lesion and is the type in which imprisonment of the detached epicondyle in the joint is most likely to occur. Two degrees of displacement are met with clinically.



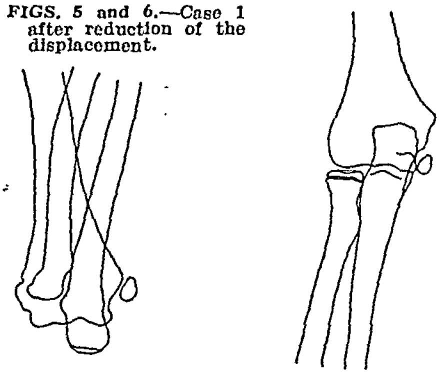
FIGS. 1 and 2.—Outward dislocation of elbow with displacement of internal epicondyle (Case 3).

1. A gross outward dislocation of the elbow exists. The epicondyle is pulled downwards and then outwards by the attachment of the common flexors until it lies below the trochlear articular surface of the humerus (Figs. 1 and 2, Case 3). In this type of case manipulative reduction of the dislocation may displace the epicondyle out of harms way. Alternatively, as the dislocation is reduced, the epicondyle becomes wedged between the trochlea and the sigmoid cavity of the ulna, producing a picture essentially similar to the second type of case.



FIGS. 3 and 4.—Outward subluxation of elbow with "nipping" of the epicondyle in the joint (Case 1).

2. In this type there is a slight outward subluxation of the elbow and the internal epicondyle is interposed between the articular surfaces of the ulna and humerus (Figs. 3 and 4, Case 1). There has probably been a dislocation of the elbow at the time of injury but spontaneous reduction has occurred. I have been unable to find any record of successful manipulative reduction of this type of displacement—chiefly I think because displacement of the epicondyle into the joint is associated in the minds of surgeons with operative reduction or removal, and consequently no attempt is made to reduce the displacement by manipulation. Two of the four cases recorded here belong to this type and have been successfully reduced by manipulation.



FIGS. 5 and 6.—Case 1 after reduction of the displacement.

CASE RECORDS

CASE 1.—A girl, aged 13, was seen by me on June 16th, 1933. On the previous day she had fallen, injuring the left elbow; the exact mechanism was not known. The elbow was very swollen and blistered and the diagnosis was not made clinically. There was a partial ulnar nerve lesion. Radiograms showed a displacement of the internal epicondyle into the joint. Tracings of the radiograms show the typical appearances (Figs. 3 and 4). In the antero-posterior view the internal epicondyle is seen with its fractured surface upwards lying in the space between the ulna and the trochlear epiphysis. In the lateral view it occupies the sigmoid cavity of the ulna.

after two and a half hours, 1 c.cm. of pure horse serum by the same route. The animal betrayed no abnormality and a post-mortem examination some three weeks later revealed healthy organs.

Familial investigation.—Both parents and the two other children of this family were submitted to skin tests with horse serum. Using a dilution of 1 : 100, there was no abnormal response in any case.

Specificity.—Final intradermal tests on the sensitive patient with the sera of the goat and cow in a dilution of 1 per cent. in the same buffer solution yielded reactions similar in nature to that obtained with horse serum, but more extensive in degree. This was particularly the case with goat serum, for the subsequent œdema was noted after six hours to cover the anterior half of the forearm with the exception of about two inches proximal to the wrist-joint. Three control patients had the cow and goat sera administered intradermally and showed no response.

DISCUSSION

Although the similarity of the events referred to in the early (1903–1907) studies of Richet,[4] Arthus,[5] and Theobald Smith [6] on animal anaphylaxis, and the researches of von Pirquet and Schick [7] on serum reactions in man, has led to a confused terminology, it has been evident that, as with immunity, there are two types of supersensitiveness, the one artificial and the other natural.[8]

According to Lamson,[9] the onset of serious symptoms of shock following horse serum injection is much more common in patients who have not been artificially sensitised by previous serum injection and who manifest their idiosyncrasy by some form of horse intolerance. Little experimental work has been carried out on the naturally supersensitive, and hence it has been assumed from work done on artificially sensitised individuals that desensitisation is possible and that the condition is specific. Mackenzie and Hanger [10] have pointed out that desensitisation of the naturally supersensitive individual had not yet been shown to be easily possible, while the case reported by us seems at least to throw the assumed specificity of natural supersensitiveness open to question. Mackenzie [11] has noted heterologous skin reactions with other sera in individuals sensitised to horse serum, and in our case the reactions with other sera were equally or more severe. The observations of Prausnitz and Kustner [12] and of Cooke and Spain [13] regarding the transference of sensitiveness have been corroborated.

The patient was evidently supremely sensitive, for the acute symptoms appeared within three minutes of the intramuscular injection. Would it have been possible to detect this sensitiveness in advance, and can we be certain that the reactions developing after the intradermal administration of horse serum, injected days after the therapeutic serum had been given, would have shown themselves had the patient been tested on admission? We shall never know. Nor are all writers convinced that the intradermal method would have given warning in advance. Some authors have suggested that a minute dose of serum should be administered by the route to be used for the main injection. In view of the intense anaphylactic shock this child showed, we think it highly probable that a preliminary intramuscular injection of even a minute dose of serum would have caused symptoms striking enough to warn us that the child belonged to this dangerous group. What then? Presumably we should have no option, if we decided to continue serum to the required therapeutic dose, but to give a long series of divided doses [14] commencing with perhaps 0·05 c.cm. of serum and increasing cautiously, keeping 1 c.cm. of adrenaline available for instant injection if troublesome symptoms appeared.

SUMMARY

We report a case of severe anaphylactic shock following the first injection of horse serum, where success attended efforts to resuscitate a patient who would in our opinion certainly have died otherwise. The value of artificial respiration coupled with prompt administration of adrenaline is clearly demonstrated.

The tests applied to the patient in convalescence are interesting for the reason that, while they confirm certain experimental work, they show that natural supersensitiveness is not necessarily specific.

We are indebted to Dr. R. A. O'Brien, of the Wellcome Research Foundation, for material help in the investigation and valuable suggestions and advice in writing this paper.

BACILLUS TUBERCULOSIS IN BUTTER

A METHOD OF EXAMINATION

By J. W. Edington, M.D. Edin., D.P.H.
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF SHEFFIELD

There are certain technical difficulties in carrying out the biological test for the presence of *B. tuberculosis* in butter. The following method obviates some of these. All operations must of course be carried out aseptically and all apparatus, distilled water, and saline used must be sterile.

From 60 to 100 g. of butter are taken and melted at a temperature of 40° C. in 150 c.cm. of distilled water in a beaker. This is then pumped twice through a "cream making" machine into a centrifuge tube. It is next centrifugalised at 3000 revolutions per minute for half an hour. The cream is then removed with the aid of a stout wire, the supernatant fluid poured off, the deposit suspended in 5·0 c.cm. of saline, and inoculated subcutaneously in equal amounts into the antero-internal aspects of the right thigh of each of two guinea-pigs, the inguinal glands having been previously squeezed after the method of Bloch.[1] The animals are killed after a lapse of one month, and examined with great care for the presence of tuberculosis arising from the site of inoculation.

By this method 40 samples of Danish (15) and New Zealand and Australian (25) butter have been examined and the organism was found in one of the Danish samples. This is rather surprising, since these butters are usually believed to be made from cream which has been efficiently pasteurised. It is recognised that the butter may have been infected after production; but it is none the less disconcerting to those who use these butters principally because of their supposed freedom from infection with *B. tuberculosis.*

SEVERE SERUM SHOCK

A CASE AND AN INVESTIGATION

BY JAMES GRANT, M.D. Glasg., D.P.H.
MEDICAL OFFICER OF HEALTH FOR THE ROYAL BURGH OF AYR; AND

MARTIN M. SCOTT, B.Sc., M.B. Glasg.
RESIDENT MEDICAL OFFICER, HEATHFIELD INFECTIOUS DISEASES HOSPITAL, AYR

THE rare phenomenon usually called "anaphylactic shock" always attracts attention, because it is an unexpected and dramatic outcome of a simple procedure almost always performed without mishap. So rare, indeed, is it in humans that few practitioners ever see a case. It has been calculated[1] that the proportion of persons liable to show severe anaphylaxis is not more than 1 in 20,000.

THE CASE

At the beginning of May, 1933, five cases of scarlet fever were admitted to hospital within four days. The patients were children who attended the same class of an elementary school within the burgh. Inspection of the pupils of the affected class by one of us on May 8th elicited the source of infection to be a girl with the remains of the rash still visible. The patient, a well-nourished child of 8 years, was removed to hospital, and there 5 c.cm. of scarlet fever antitoxin (concentrated) out of a 10 c.cm. phial was injected into the muscle of the thigh. Three minutes later she suddenly began to have difficulty in breathing, and after struggling into a sitting posture with the arms held firmly to the sides and the hands clenched, gasped for breath. The colour became greyish-blue and the face distorted, with the mouth pulled to the right and the lips retracted over the teeth. The child was at once put on her back, but she writhed about on the bed and ultimately lay on her left side in a state of deep coma. Respiration was suspended and the colour became an extremely livid blue,[2] as in death from asphyxia. The pupils were contracted, but the pulse was full and bounding.

Treatment and course of illness.—At once artificial respiration was initiated with the jaw held forward and, in approximately one minute, a sighing type of respiration, attended by a rattle of mucus in the air-passages, was re-established for a few moments. The lividity of the skin, however, remained. The patient was at once given gr. 1/100 of strychnine sulphate and ♏ 8 of adrenaline solution hypodermically. Almost at once respiration ceased again, accompanied by a tonic spasm of all the muscles. The radial pulse became imperceptible, although the heart was felt to be beating tumultuously. Artificial respiration was recommenced, along with rhythmic traction of the tongue. The heart area was fomented, the mouth and lips rubbed with brandy, and the foot of the bed elevated about two feet. The patient voided urine during the asphyxial spasm. After a few minutes breathing of a more normal type became established, the livid colour began slowly to fade, and consciousness gradually returned.

The child remained dazed for half an hour afterwards and a degree of cyanosis was present for about two hours, while the radial pulse remained imperceptible for a similar period and then gradually grew stronger. The scarlatinal rash faded during the attack and began to reappear with the disappearance of the cyanosis. Subsequently the child was very thirsty but slept well during the night. Next morning she was rather pale, but her pulse was quite strong. There were a few urticarial weals on the abdomen. Progress after this was normal and free from other serum reactions, and the child was discharged from hospital on June 10th in perfect health.

Sera from the same batch had been used on other patients in this ward without any subsequent manifestations and, moreover, the remaining 5 c.cm. of serum in the 10 c.cm. phial opened for this patient was administered at the same time to another patient, whose clinical behaviour subsequently was entirely normal.

Previous history.—Apart from measles, whooping-cough, mumps, and influenza the child had enjoyed excellent health. She had had neither hay-fever, asthma, migraine, nor a previous injection of horse serum. No animal intolerance had been noted. Ordinary colds in the head were admitted, but no seasonal colds suggestive of hay-fever. Her own doctor corroborated this history.

THE INVESTIGATION

During convalescence attempts were made to inquire into the pathogenesis of this susceptibility and to evaluate the various modes of testing for the condition.

Scarification tests.—These were carried out, a week after admission, on the patient and two control subjects, one of whom had also previously had an injection of 5 c.cm. of scarlet fever antitoxin. The substances applied were undiluted ox, human, pig, and sheep sera, along with two samples of therapeutic horse serum from different makers. None of the three subjects showed any response. Two group-protein extracts (meat and bacteria) were similarly used without any reaction.

Conjunctival and intradermal tests.—Beginning on the twenty-first day, these were carried out on successive days on the patient and one other control subject, using varying dilutions of serum in a buffer solution of isotonic saline. The results are given in tabular form.

Material.	Method.	*Dose.*	Result.	
			Patient.	Control.
1. Buffer solution	Conj. Intrad.	2–3 drops. 0·1 c.cm.	Neg. ,,	} *Neg.*
2. H.S. (1 : 1000)	Conj. Intrad.	2–3 drops. 0·1 c.cm.	Neg. Sl. erythema and œdema.*	} Neg.
3. H.S. (1 : 100).	Conj. Intrad.	2–3 drops. 0·1 c.cm.	Neg. Marked weal, erythema and œdema.†	} *Neg.*
4. H.S. (1 : 10)..	Conj.	2–3 drops.	Neg.	Neg.
5. H.S. (pure) ..	Conj.	2–3 ,,	Neg.	Neg.

H.S.=horse serum; conj.=conjunctival; intrad.=intradermal; neg.=negative; sl.=slight.
* 1–6 hours after. † ½–6 hours after.

The reaction obtained on the patient following intradermal injection with horse serum in a dilution of 1 in 100 was the formation within half an hour of a marked weal with a surrounding zone of erythema of about 2 inches diameter, which gradually faded and was succeeded by a larger ovoid area of œdema reaching a maximum length of 3 inches within six hours afterwards. These changes are comparable with the triple reaction of Lewis.[3]

Transference of sensitiveness.—(*a*) Ten c.cm. of blood were withdrawn from the patient and allowed to coagulate; 0·1 c.cm. of the serum was injected intradermally into a second patient, who had previously been tested by the intradermal method and found insensitive. A latent period of 48 hours was allowed to elapse and the sensitised site was reinjected intradermally with 0·1 c.cm. horse serum in 1 : 10 dilution. A very mild erythema with local œdema lasting eight hours followed. A control injection into an untreated area of the skin gave no reaction. (*b*) An attempt was made to transfer the condition to guinea-pigs. (Dr. M. J. Miller, of Ayr County Laboratory, very kindly conducted this part of the test.) A guinea-pig was given an intradermal injection of the patient's serum and, after two hours, an intradermal injection into the same site of pure horse serum. There was no abnormal response. A second guinea-pig was given 1 c.cm. of the patient's serum hypodermically and, generations of mental nurses, and greatly enhancing the prestige of psychiatry. Until the war most of the practical improvements, discoveries, researches, and reforms in connexion with psychiatry emanated from mental hospitals; a galaxy of "asylum men," as they were called, brought honour to themselves and the specialty by their ability and devotion. But since the war a change had come about associated with two important developments. The first was the greatly increased attention devoted to research by a multiplicity of research workers. In most of the mental hospitals of any size the clinical and pathological laboratories and staffs compared most favourably with those of any general hospital in the country. Yet research in psychiatry at the present time bore, on the whole, far less relation to clinical work with and for patients than in any other branch of medicine, for pre-eminently in psychiatry the physician dealt with personalities. It should not be a question as to the results which "A" had collected, of "B's" investigation into the chemical properties of certain organs and tissues removed by "C" from 200 cadavers of persons who, in "D's" opinion, once suffered from schizophrenia. That had no message for clinical psychiatry. There was too great a gulf between research and the clinical phase of psychiatry. It was assiduously preached, and had become widely accepted, that not only was mental hospital experience needless for the training of the psychiatrist, but it was a waste of time, if not indeed harmful. The situation needed to be frankly faced.

The second great post-war change was the great development of medical psychology, the evolution of the modern theories of the neuroses, and the amazing increase in the recognition and effective practice of psychotherapy. The latter was quite unfitted for institutional work; so far as the psychoses were concerned it was a broken reed, as mental hospitals were not the right places for neurotic patients. The neurologist or neuro-pathologist pointed to his research laboratory "free from the taint of lunacy," and, on the other hand, the trouble with the psychologically minded psychotherapist was that he lacked clinical training in psychiatry, and so was forced to avoid the formality of diagnosis in every second or third case which he treated. This the speaker regarded as a sad and serious situation which ought to be faced. A large number of highly trained scientific men and women gloried in the fact that they had had little or no experience in a mental hospital, and they neglected no opportunity of belittling the work done in mental hospitals and the treatment to be gained in them. Why did not psychiatrists speak in their own defence? The polite and good-mannered depreciation of which he was complaining was much more deadly than any attacks by a poorly informed yellow press, and the profession as a whole should inform itself on the subject and stop the misrepresentation as far as possible. The Board of Control was the best friend that either the patient or the medical superintendent could have, yet the mass of the public seemed to fear and distrust that body. If more effect had been given to its views in the Mental Treatment Act, that Act would have been a better measure.

Dr. Yellowlees suggested that instead of keeping mild or recoverable or well-behaved cases out of mental hospitals, the confirmed and chronically insane should be removed into special institutions. By removing the supply of cheap unskilled labour the whole industrial and social aspect of the mental hospital would be altered, but this course would emphasise the strictly medical aspect of it, and it ought to satisfy those whose cry was for a curative clinic. His only other suggestion was a better education of both professional and public opinion. Something might be done towards this by the issue of a pamphlet which nailed to the counter some of the grossest of misrepresentations.

Dr. HAMILTON MARR (Scottish Board of Control) did not agree with Dr. Yellowlees' proposal to take from mental hospitals the chronic and apparently incurable cases; rather would he extend the sphere of mental hospitals to include care of cases before they became certifiable. He commended the example set by two or three mental hospitals in Paris, where members of the staff were required to have had four years' practice in mental institutions and to have passed two special examinations.

Dr. ISABEL WILSON suggested it might be possible to create assistantships in mental hospitals for six to twelve months for the benefit of those who had started analytical work.

Prof. D. K. HENDERSON said it was not his experience that the average junior medical officer assistant coming into a mental hospital minimised the importance of clinical psychiatry. Like Dr. Marr, he objected to the proposal to shift chronic patients from the mental hospital and place them into special institutions by themselves. These cases needed the same standard of care that other kinds of patients did.

Dr. ROLF STRÖM-OLSEN (Cardiff Mental Hospital), in association with Dr. MURIEL L. MCCOWAN, read a paper on

Prolonged Narcosis in Mental Disorder

Though the value of prolonged narcosis in mental disorder had been well recognised in Switzerland, Germany, Holland, and the United States, there had been as yet little tendency, he said, to use it in this country. A statement as to its dangers had deterred many psychiatrists from giving the method a trial. In the search for a perfect narcotic 40 substances had been tried. This paper set out results achieved in 107 mixed cases of mental disorder. In 117 of 128 separate treatments somnifaine was used, in 9 veronal, in 2 Dial. It was not yet possible to say in what forms benefit was most likely to accrue from this, as the rationale of the treatment was not properly understood. The therapeutic action seemed, however, to depend on two phenomena: first, the removal of inhibition or the discharging of libido from repressed complexes; and, secondly, the stage of narcotic sleep. This series of cases suggested that a degree of narcosis was required which would cause a deep sleep, as a "twilight sleep" was, in most cases, insufficient. In schizophrenia the best results were achieved in the excited or depressed phases. In this present series the most gratifying results were in 13 cases of psychoneurosis. Reassurance and suggestion were constantly used beneficially as additional means. He described in detail the technique followed, and tabulated the results, giving histories of a variety of cases.

Dr. K. C. L. PADDLE (Caterham Mental Hospital) said that the cerebro-spinal fluids of 2000 cases of mental deficiency of both sexes, and of all grades and ages, were examined. In 1500 of these cases, observations were made on the after-effects of lumbar puncture. 17 per cent. of these cases developed post-lumbar-puncture symptoms, 14·2 per cent. vomited, 6·8 per cent. had headache, and 0·73 per

MEDICAL SOCIETIES

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION

THE annual meeting of the Association took place at the Guildhall, Northampton, under the presidency of Dr. DANIEL F. RAMBAUT (St. Andrew's Hospital, Northampton), who gave an address on

Some Mental Treatments

In 40 years he had seen many changes in treatment of mental disease. Good nursing was essential. Originally the mental nurse was but a warder or keeper, whose purpose was to protect the public, not the patients. The great change from that was initiated by Pinel in Paris, and William Tuke in York Retreat, coupled with the great reforms of Lord Shaftesbury, embodied in the Lunacy Act of 1845 and the Lunacy Commission of 1859. The greatest credit for the change to the present efficient system must be attributed to the committee of the Medico-Psychological Association which, in 1890, resolved that it was advisable (1) to institute a system of training attendants in asylums, (2) to establish examinations in order to test the proficiency of candidates, (3) to grant certificates to those who succeeded at examinations. Commencing with 106 certificates, the number of candidates last year was 6920. Under the Association's scheme nurses could consider themselves established, could look forward to promotion, and to filling comfortable positions. One effect of the training was to show that roughness and tactlessness were due to ignorance, and nurses and attendants came to realise that they were treating illness. The quality of a nursing staff was largely dependent on the wages offered, but it depended partly also on the reputation of a particular hospital for making nurses comfortable and happy both at work and off duty. Nurses at St. Andrew's were encouraged to pursue their studies in general hospitals and to complete their general training there, and sisters having this dual training were appointed to senior posts, and invariably into the acute wards. He, like others, had found distinct benefit from having female nurses in male acute wards. Many cases of apparently unavoidable artificial feeding had on this account been fed naturally. He thought the example of Holland should be followed in giving young nurses a course in general education and knowledge, and this should be given by each mental hospital as part of the general course of instruction.

The President then sketched in detail the evolution of occupational therapy in mental treatment. Selection of the most suitable form of activity was of the greatest importance. The provision of reception hospitals he regarded as of great importance, as classification was essential for proper scientific investigation and treatment. Most mental hospitals were too large, their wards contained too many patients, and there was little possibility of therapeutic isolation or of differential grouping. The St. Andrew's Hospital Committee had now erected a reception hospital, Wantage House, whose entrance was separate from the main hospital, and it had its own gardens and recreation grounds. Its patients did not come into contact with the more chronic cases. Here, too, the distinctive features of patients who did not quickly recover could be carefully studied. The main aim of a reception hospital for acute psychoses must be the provision of adequate facilities for psychological and physical treatment. He stressed the value of hydrotherapy in the psychoses of toxic origin. Through the somatic treatment of mental disorders the speaker had seen a complete change introduced into the spirit of a mental hospital, as patients felt they were undergoing care for an illness, and were anxious to coöperate. This feeling had gradually permeated the whole hospital, with a corresponding improvement in the atmosphere.

Mrs. ELEANOR SLAGLE (Director of Occupational Therapy, New York State Department of Mental Hygiene) read a paper on

Occupational Therapy

She said that in the various institutions for mental or defective patients in New York State there were now 200 patients to each physician, but the proportion aimed at was 1 to every 150. Statistics showed that 45 out of every 1000 born in the State would, at some period of their lives, be affected with mental disorder, the expectancy being higher among women than among men. Last year 34,548 patients had occupational treatment, and great improvement was noticeable as a result. The aim was the social rehabilitation of the patients and habit training was specially attended to. Mrs. Slagle gave detailed schemes for various grades, and said that the medical staff prescribed the actual treatment programme of individual patients, and the nurse was shown the value of harmonious coöperation. Activities included the training of nurses and attendants.

Prof. W. M. von d. SCHEER (Grotingen, Holland) said that in the psychoses, which disorganised the higher functions of man, numerous therapeutic successes had been achieved, notably *malaria therapy* in dementia paralytica, salvarsan and tryparsamide therapy for cerebral syphilis, treatment of digestive apparatus in toxæmic psychoses, the removal of septic foci in cases of schizophrenic derangement, the Somnifaine sleep treatment of manic-depressive psychosis, and non-specific stimulation treatment in various other psychotic conditions. Yet the specialty was still to a large extent powerless in direct treatment. Great hope centred in occupational therapy. He declared that prolonged restlessness in wards need not occur, that baths were scarcely ever needed as a means of restraint, and that it was very seldom necessary to use isolation cells. Narcotics, too, could be reduced to a minimum. It was clear to him that the greater number of cases of unsocial behaviour had little to do with the specific psychoses as such; the behaviour departures were largely due to a disordered nervous system which was reacting wrongly to the stimuli of the external world. In Holland, work-therapy in mental hospitals had reached a high level. In his own institution no difficult work was expected of patients, and they worked in the immediate neighbourhood of the wards, so that disturbing elements could be at once removed. Promotion of patients to a higher class as a reward of effort always had a good effect, as did encouragement to take walks unattended. In the whole community order and self reliance were aimed at.

Dr. HENRY YELLOWLEES read a paper on

Modern Psychiatry and Mental Hospitals

He reminded members of the large share taken by the Association in organising the teaching of after the operation and lasting for the whole of the remaining life. This fact assigned great importance to the nature of the secretion of the anterior lobe of the pituitary. In hypophysectomised animals it was possible to restore activity without restoring sex activity. It was most probable that the actual physiological state of the individual to some extent determined its behaviour in any given situation. In the case of rats which were wild and brutal this attribute was lost a few days after removal of the anterior lobe of the pituitary, and it seemed that many of the factors responsible for highly dynamic motivation were associated with factors responsible for sex behaviour. Cushing's cases of adenoma of the pituitary had loss of the libido. In the female the conditions were more complicated, but there were a set of chemically definable factors which were responsible for sex expression. In the female there occurred the element of periodicity of sex manifestations and of reproductive drives in the proper sense. There were many activities in the care of the young, but they were to some extent motivated by chemical factors belonging to the hypophyseal and ovarian mechanisms. It was possible to evoke certain partial drives and maternal behaviour in virgin rats by appropriate endocrine treatment. Cannibalism was never observed in virgin rats. Dr. Wiesner's recent work had shown that environmental factors played an equally great rôle, though at present the relation between the physiological and environmental factors was not understood.

Dr. H. **Gardiner-Hill** said that a study of this subject must include hermaphroditism and sex reversal, the underlying pathology of which was little understood. As a physician his thoughts tended to the endocrine aspects of the problems. Presumably the chromosomal constitution was subsequently modified by other influences, endocrine and environmental. With regard to the former of these, it was now generally accepted that the hormonic stimulus which led to the growth of the secondary sex organs and characters came from the gonads themselves. Prepubic castration in the male resulted in underdevelopment of the sex organs, prostate, seminal vesicles, absence of beard, and the retention of the treble voice, while ovariotomy in the female led to corresponding differences. Cortical tumours were associated with varying degrees of virilism in the female, and it was thought that a hormone was produced which had exerted a masculinising influence. In cases of hermaphroditism one found generative cells peculiar to both sexes, and they possessed the so-called ova-testes, and these cases usually had feminine sex characters. Another group was that having the adreno-genital syndrome. The association of lesions of the adrenal cortex with virilism was well known. The pathological lesion might be a diffuse cortical hyperplasia or an actual neoplasm. In adrenal pseudohermaphroditism there were seen to be bodily developments towards the male type, associated with the internal sex organs of the female. Gross cases of these abnormalities were rare in comparison with people who had departures in minor degrees. The view must be accepted that the development of sex characters depended on a number of factors, but the pre-existing chromosomal constitution was very important.

Sir **Bernard Spilsbury** confined his remarks to the abnormality known as masochism, the rare cases of which led to medico-legal implications when the death of the individual occurred during the performance of the act. In this condition the individual subjected himself to severe physical restraint with the object of giving himself sexual gratification. His inquiries had led him to believe that the vice was accidentally acquired in early sexual life. A difficulty from the medico-legal point of view was that the rite was usually practised in secret, and the friends and relatives had no suspicion of it; therefore in a fatal case there was no clue to go upon except the surroundings at the scene of death. For this reason suicide was a very likely verdict in these cases, or even murder. He described in detail, aided by photographs, the case of a Cambridge undergraduate who was found dead in his chambers three years ago, whose death was for some time considered to have been due to a college "rag," but was found to have been a case of masochism. In this and two others which he described the death was an asphyxial one; whether the attempted asphyxia was the stimulus to the sexual act, or whether the asphyxia was the chief accidental cause of death in these cases it was difficult to say.

The **President** said that some cases of intersexuality he had encountered caused him grave perplexity, and he had hoped that Prof. Crew would have touched on practical difficulties. It was impossible until the eighth week of fœtal life to say whether the genital organs would be male or female—i.e., whether a Müllerian duct or a Wolffian duct would develop. Seeing that all must be, at some stage, bisexual it was difficult to say, when intersexuality arose, whether a person would be a man or a woman. He had always thought it important to consider the endocrine action, the suprarenal cortex, the pituitary, and the thyroid, as well as, to some extent, the pineal gland. C. J. Bond had reported the case of a cock pheasant which was a cock on one side, a hen on the other, and it was interesting to speculate how the chromosomes got to be so beautifully divided on opposite sides of the body. He, the speaker, had had four cases of pseudohermaphroditism referred to him in one month, and he operated on all four to decide as to the kind of gonad present. In each case he found a normal ovary. In these cases the secondary sex characters were of opposite kind to the anatomical structure of the gonad. Also, in pseudohermaphroditism one always found that the secondary sex characters of the female were much more perfect than were the sex characters of the male. In this condition, too, the ovaries were always more fully developed than were the testes. He contended that the law was wrong when it declared that an individual was a male or a female according to the nature of the gonad.

Dr. **Leonard F. Browne** remarked that masochism showed many forms of expression, but many, fortunately, did not lead the perpetrator into risks. There was also the opposite condition, sadism, in which the individual, instead of seeking to suffer pain, wished to inflict it on others. Recently a man was sentenced to 18 months' imprisonment for thrashing a girl in a garage. On appeal, that sentence was quashed. He asked whether, in the cases of masochism described by Sir Bernard Spilsbury, there was evidence of loss of semen.

Mr. **Lennox R. Broster**, speaking of the appearance of secondary male sex characters in the female, said these had been associated with changes in the adrenal cortex, but, so far, no one had demonstrated any change in that association. Operation had been done on 16 cases which were clinically classified by Dr. Gardiner-Hill as of this type, and in each the cells of the adrenal cortex were bright red, a condition not found in the adrenals of the normal person. A similar change was found in the anterior lobe of the pituitary, and in the interstitial cells of the testes. In seeking for an explanation, many fœtal adrenals were cent. pyrexia up to 101° F. The incidence of vomiting was nearly twice as high in females as in males, being 20·1 per cent. and 10·5 per cent. respectively. It was also higher in the feeble-minded group than in the imbecile or idiot group. There was a direct relationship between the rate of flow of the cerebro-spinal fluid and the incidence of post-lumbar-puncture symptoms. Where the former was rapid the incidence tended to be high, and where it was slow the incidence was relatively low. The tests used on the cerebro-spinal fluid were the Wassermann reaction, cell estimation, Pandy and Lange's colloidal gold; also the acetic anhydride of Boltz. Many pseudopositive Pandy and Boltz reactions were given by the fresh cerebro-spinal fluid. Of the 2000 cerebro-spinal fluids examined, 55, or 2·7 per cent., were abnormal. The Wassermann reaction was positive in 19 cases; excess of cells existed in 32, excess of globulin in 44, and the colloidal gold reaction was positive in 30. 23·9 per cent. of congenital syphilitics had abnormal cerebro-spinal fluids. The incidence of abnormal cerebro-spinal fluids was higher in cases of mental deficiency complicated by epilepsy or paralysis than in uncomplicated cases. The cerebro-spinal fluid of only 1 out of 54 Mongolian idiots gave a positive Lange's colloidal gold test. In the remaining 53 the cerebro-spinal fluid was normal in every respect.

During the meeting the Gaskell Prize and Gold Medal were presented to Dr. William Blyth, of Paisley District Mental Hospital, the divisional prize to Dr. E. J. Fitzgerald, and the bronze medal and prize to Dr. H. C. Beccle, of Springfield Mental Hospital, Tooting.

At the business meeting Dr. James Whitwell, who has done much for the library of the Association since 1927, and Mr. L. G. Brock, chairman of the Board of Control, were unanimously elected honorary members of the Association.

ROYAL SOCIETY OF MEDICINE AND MEDICO-LEGAL SOCIETY

A JOINT meeting of the section of obstetrics and gynæcology of the Royal Society of Medicine with the Medico-Legal Society took place at the headquarters of the former, and was very largely attended. The chair was taken by Prof. W. BLAIR-BELL, president of the section. The subject of discussion was

Sex : its Nature and Abnormalities

considered from Biological and Legal Points of View. Prof. F. A. E. CREW (Edinburgh), in opening, said it was customary, when seeking an understanding of the attributes of man in a complex society, to make a broad survey of similar phenomena in other forms of life. But human society presented a unique biological phenomenon, and it was doubtful whether there existed anything like it in the experimental material available to the biologist. Among animals there was no sin, but it must be assumed there was much crime, and it was to be doubted whether the student of human behaviour could hope to find explanations of things which puzzled him by turning to the rabbit and the bird. The biologist was no longer concerned with a search for an understanding of the nature of sex; he contented himself, in this stage of development, with a discussion of the analysis of the differences which permitted him to regard one individual with one kind of organisation and characterisation as a male, and another and contrasted kind of organisation as a female. In fact the more one knew of sexual differences, the less one felt one knew about sex itself. The mating of two dissimilar individuals, bearing the egg and the sperm, commonly resulted in the union of two dissimilar gametes, and it was easy to conclude that the meaning of sex could only be recognised by bringing it into essential relation with reproduction, the preservation of the species. Sexuality and reproduction, though commonly inter-related, could be completely dissociated. Many advantages had been gained as a result of our mode of evolution, but many more had been lost. In an ever-increasing number of species the existence of a sex chromosome had been demonstrated, and it was further established that in a considerable number of instances there was a dissimilarity in the matter of the sex chromosome constitution. The male was constitutionally heterogametic, the female constitutionally homogametic. Abnormalities in the distribution of the sex chromosomes were always associated with abnormalities in the sex characterisation of the individual. In one kind of fly it was possible to draw a line from its tip to its tail and demonstrate that all the characters on one side of its body were male, whereas all those on the other side were female. In that species of fly there could be a graded series of abnormal sexual types. In one fly there might be only one-sixteenth of the body male; according to the time at which it happened, there would be a larger or smaller area of male tissue in a creature which was otherwise preponderatingly female. Male-determining factors could differ amongst themselves in potency, and the female-determining factors could vary amongst themselves. Males could derive determinations from either father or mother, and as a result there could be an individual containing both male and female factors.

As a result, he asked subsequent speakers to try to *define what was male and what was female*, as, frankly, he did not himself know. In the case of binelia, a marine worm, at one stage the larvæ floating on the surface were all alike, and their sex was subsequently determined by accident. If they settled on the long proboscis of the female they became males, but if they settled well away from the female they became females. The biologist therefore, if appealed to on this matter, would probably confess that he had no knowledge as to the nature of sex.

Mr. B. P. WIESNER, Ph.D. (Edinburgh Biological Laboratory), spoke on mechanisms which regulate sex behaviour and associated activities. This analysis could be carried out on an entirely psychological basis. No such analysis had been attempted, and he did not think it would be as long as the historical attitude of the psycho-analyst ruled. In the past much confusion had resulted from the identification of motivation concerned with the offspring with that of sex drives. In humans complicated outside factors operated, but in the case of the rat, the male animal tried to mate with any other animal of its kind or of similar appearance, whether such animal be male or female; distinction of sexes in this matter was not a primary activator in animals. Selection of the female by the male was determined rather by the opposition on the part of the male to sex attentions by another male, and only the female would assume the necessary posture for reproduction. The testes could be removed after puberty without interference with the sex life of the animal, but complete removal of the anterior lobe of the pituitary resulted in the complete disappearance of all sex drive and the assumption of complete sex indifference, this changed attitude coming on 24 hours tissues can determine the diagnosis. They also point out the difficulty of avoiding radium necrosis of bone when treating certain lesions, particularly in the superior maxilla, and they accept Regaud's suggestion that this special susceptibility is due to the mineral salts in the bone producing secondary radiations. They consider that more careful dosage and increasing the time during which the radium is allowed to act should minimise these injuries.

The last two chapters deal with poisoning by radio-active substances and "X ray and radium quackery." In few words they paint an unforgettable picture of the terrible results which followed the ingestion of radium by girl workers in the famous New Jersey dial painters case, and also in several cases where radio-active water had been taken for therapeutic purposes. No doubt remains that poisoning by radio-active substances produces painful and fatal diseases, and readers will agree with the conclusion that legislation to schedule these substances as poisons is already overdue. An appendix gives us the recommendations of the X Ray and Radium Protection Committee, and a clear account of the methods of dosage at present in use.

There is an excellent bibliography, which completes a work of reference which should be studied not only by every radiologist, but by every practitioner who employs either radium or X ray in the treatment of his patients.

Management of Fractures, Dislocations, and Sprains

By John Albert Key, B.S., M.D., Clinical Professor of Orthopædic Surgery, Washington University; and H. Earle Conwell, Orthopædic Surgeon for the Tennessee Coal, Iron, and Railroad Company. London: Henry Kimpton. 1934. Pp. 1164. 63*s*.

This book on fractures deserves similar welcome from students, general practitioners, and surgeons. It is a complete account of modern ideas and methods, and in spite of bulk, contains no obvious redundancy; each injury is treated from every aspect, but nothing is included that has not practical value.

The introductory chapters give a short account of modern views on the repair of fractures, setting side by side the osteoblastic theory of bone-formation, in which the bone cell is considered the determining factor, and the theory which regards osteogenesis as a function of de-differentiated mesoblastic tissues occurring in the presence of an excess of calcium. In a short discussion of X rays in the treatment of fractures the authors express the view that it should be possible to diagnose and treat many fractures without radiography: protesting against the pressure put on doctors to obtain X rays of every case of suspected bone injury. There are descriptions of plaster-of-Paris technique, of extension methods, of open operation, and of the method of local anæsthesia for reduction of fractures. The chapter on compound fractures will be found a useful guide to the indications for débridement, primary suture, and inaction alone. This chapter is a good example of the method used throughout the book of teaching principles and encouraging thinking.

In the sections dealing with individual fractures the descriptions and illustrations are informing. Where two or more methods are considered by the authors to be of proved value details are given of each, and no method is mentioned that is not described. Little fault, we imagine, will be found with the selections of treatment, though some will regret that Robert Jones's flexion method in the treatment of fractures round the elbow should be condemned with what is, perhaps, rather a lack of understanding of his original description. The Sinclair glue extension is dismissed in words that suggest the details of its application have not been mastered. Special writers have dealt with fractures of the skull and of the face. The chapter on fractures of the skull and brain trauma, contributed by Dr. Charles E. Dowman shortly before his death, is an admirably clear exposition of a difficult subject. One correction seems to be called for. On p. 513, in a description of the method of reducing a supracondylar fracture of the humerus, it is rightly advised that the final manœuvres should take place with forearm in the pronated or partly pronated position, to obviate the danger of inward angulation of the lower fragment. A reference is given to a photograph on the next page which shows the manipulation being performed with the forearm held in very full *supination*. We do not agree with the suggestion here made that "perhaps the majority of men who treat fractures have relatively little interest in these lesions and expend as little labour and time on their fracture cases as possible." Anyhow, those who do regard such cases as uninteresting will find in this volume much to stimulate them to reconsider the attitude.

Formes chirurgicales de la tuberculose intestinale

By L. Bérard and M. Patel. Paris: Masson et Cie. Pp. 264. Fr.50.

There are but a limited number of general surgeons who can claim to have a considerable experience of intestinal tuberculosis. For others this monograph is invaluable, since it gives an account of the various tuberculous lesions met with in the intestine for which surgery is indicated. Not only is the pathology of the several conditions well described, but the means of diagnosis, the indications for surgical intervention, the correct choice of procedures, and the probable outcome are so clearly expounded, as very largely to compensate for small clinical experience. On these grounds the book can be warmly recommended. It is completed by a really good bibliography.

Aids to Neurology

By E. A. Blake Pritchard, M.D., M.R.C.P., Assistant Physician, Hospital for Epilepsy and Paralysis, Maida Vale. London: Baillière, Tindall and Cox. 1934. Pp. 376. 5s.

By the use of small yet clear type and thin yet opaque paper, the author of this latest addition to the Students' Aid Series has contrived to compress much knowledge into little space. The book slips into the pocket easily, and since it is intended for students "in the early years of their medical training" the facts are presented in as simple a manner as possible, without discussion of theories and with a minimum of anatomical detail. On the physiological side more is said, and this is to be recommended, for after all the study of symptoms is the study of functions. A general introduction on semeiology is followed by descriptions of syndromes and symptoms resulting from disease of the principal divisions of the nervous system—peripheral nerves, spinal cord, brain, and autonomic system respectively. In each of these sections the main morbid states likely to be seen by the student are examined seriatim, their causes specified, examined, and it was found that in all the males there was a marked eosinophil reaction between the 9th and 20th weeks; in the female this was present between the 10th and 15th week, but not so marked as in the male. The appearance of the eosinophil cell seemed to be associated with male characters. He thought it could be argued that there was a prolonged male phase in the female fœtus, and at an early stage that phase might be able to convert that fœtus into an undeveloped male at birth, and that might be the explanation of many of the forms of pseudo-hermaphroditism seen. Some of these abnormal cases could be classified into psychological types, and homosexual behaviour between women might be a manifestation.

Dr. MARGUERITE LOWENFELD said that in children the desire to tie themselves up, or to tie other children up, as described by Sir Bernard Spilsbury, was common, as was the desire to subject others to pressure on the windpipe. It seemed to be implanted in the minds of certain individuals, and did not necessarily have reference to the postpubertal period. She did not remember a case in a girl. Usually it occurred in association with other factors which showed that the individual was at any rate of neurotic constitution.

Prof. CREW, in reply, pointed out that in cell division nothing was commoner than for some chromosomes to get lost. Many abnormalities were due to an irregular and unusual distribution of chromosomes carrying genes which took the forms of disease. Most of the conclusions arrived at in respect of the human subject stood in need of re-examination. He had had sent to him quite 150 cases with an enlarged clitoris and otherwise a reproductive architecture which was largely female. But inside there were found testes, uterus, broad ligament, vasa deferentia, prostate, &c. He preferred to regard such a person as a male, especially as he believed there was no ovarian tissue there.

Sir BERNARD SPILSBURY said that he did not remember a fatality due to masochism occurring in a female. In reply to Dr. Browne, there was no evidence of ejaculation of semen in any of the cases he had quoted; but in the third case the individual evidently expected to have such an ejaculation as he was found wearing a condom. The others died before the expected conclusion had had time to materialise. He was interested to hear that this tying up practice occurred in the prepuberty stage in some; after puberty this kind of practice took on a sexual significance.

REVIEWS AND NOTICES OF BOOKS

X Ray and Radium Injuries

Prevention and Treatment. By HECTOR A. COLWELL, M.D., Ph.D., M.R.C.P., D.P.H., and SIDNEY RUSS, C.B.E., D.Sc., F.Inst.P. The Barnato Joel Laboratories, Middlesex Hospital. London: Humphrey Milford, Oxford University Press. 1934. Pp. 212. 14*s*.

THIS is a clearly written account of the various injuries which may result from therapeutic radiation carelessly administered or from the exposure to X rays or radio-active substances which cannot be entirely avoided by workers in this field. The book is arranged in a series of chapters, each of which deals with effects on one of the systems of the body, and this methodical attack on the subject gives a very complete picture. Experimental work of importance is briefly described with an eye to essentials, and the type of injury caused by excessive exposure, together with the reactions which may be expected in different tissues, are discussed. The skin is the subject of the first chapter, because it is so frequently, and sometimes so disastrously, injured, and also because the reactions observed in the skin have formed the basis for dosage in practically all X ray and radium therapy. Although the authors hope that X ray cancer in radiologists will become so rare as to have only historical interest, a most interesting description of the development of the neoplasm is given; they believe that once it is established treatment, to be successful, must be drastic. They advise a wide removal of the local growth, followed, if a histological diagnosis of cancer be made, by excision of the supratrochlear and axillary glands, with the lymphatic trunks between.

The section on the circulatory system is of particular interest for the clear account of the recent work by Yoffey and others on the function of the lymphocyte and its relation to the hæmopoietic organs. While admitting that this work is still controversial, the authors find it very suggestive, particularly when considered in the light of the tissue culture experiments of Maximow and his school, who showed that lymphoid tissue grown outside the body could give rise to typical myeloid elements. They believe that if the idea that the lymphocyte is a forerunner of the red blood corpuscle is accepted, it may prove to be the explanation of certain important radiation effects, and that a new and possibly fruitful field is open for investigation.

The effects of radiation on the generative organs are also described at length. These are of great scientific importance, because it was as a result of observations on the testes and ovaries that Regaud and his co-workers demonstrated the variations in radio-sensitivity which form the basis of his theory of selective action, and of a definite time factor. Their clinical importance is equally great. Radiation is now an accepted method of treatment for carcinoma of the uterine cervix, and for many cases of myoma of the uterus and menorrhagia, so that we must know what effect this radiation will have on the reproductive system of the woman, on the ova in the radiated ovary, and on the fœtus in cases of pregnancy. The authors conclude that radiation during pregnancy is unjustifiable, except in the presence of malignant growth, in which case the fœtus must be sacrificed. As regards the result of therapeutic radiation of the ovary they are more cautious; they agree with Murphy that it cannot be definitely stated that preconception radiation has a deleterious effect on the offspring, but consider that this verdict of "not proven" should not be made the excuse for indiscriminate radiation of the ovaries of young women for conditions which can be otherwise treated.

From the clinical point of view nothing is more important than the description of the reactions and sequelæ which may follow the therapeutic use of radium. This section of the book is of special interest in view of Dr. Coutard's warning in our last issue. The authors remind us that late complications may appear at any time from six months to three years after treatment, and that these late radium reactions may so simulate recurrence of the malignant disease that only careful histological examination of the

MODERN PHYSIOLOGY

IN the more stabilised sciences certain guiding principles have long been established, and the navigator on the ocean of research is able periodically to check his position with the sextant; in physiology he sails largely by "dead reckoning," and his course is only taken as correct when other explorers have charted the same seas by similar methods and confirmed it. Few have sailed so widely as Prof. BARCROFT, and his experience enables him in his newest work[1] to survey the details of such voyages as appear to him to indicate the existence of certain landmarks.

He takes first the dictum of CLAUDE BERNARD: "La fixité du milieu interne est la condition de la vie libre." Characteristically, the question is emphasised—how does the increasingly delicate control of higher animals over their internal environment help them towards a freer life? The principle of storage is then introduced; it rests on the thesis that an intermittent external supply cannot be translated into internal constancy unless depôts are laid down to be drawn upon when required. In spite of mechanisms calculated to keep constant the "milieu interne," and notwithstanding the existence of stores, there is a limit to which any single system can respond to a change in activity of the organism. For instance, although the tissues do not use all the available oxygen in the blood while at rest, during muscular activity the spare oxygen would be insufficient in itself to meet the situation; a greater number of capillaries must be opened, the output of the heart increased, the respiratory movements augmented, and so on. This introduces the principle of integration; in the author's own words: "Every adaptation is an integration." In contrast to this is the principle of antagonism; constancy of an entity such as muscle tone does not indicate inertia, but rather the balance of opposing forces such as excitation and inhibition; this makes for rapid and efficient adjustment. The latter may be achieved by "heightening the efforts of units already functioning or by marshalling a greater number of units," and so we have a discussion on "units" and the "all-or-none relation." A matter bound up with delicacy of response is the possible existence of a crude mechanism which has been overlaid, but not entirely supplanted, by a more refined one, and the principle of duplication of mechanism is suggested. Then how are we to measure the activity of a tissue? To take as a standard its resting activity is to adopt a notoriously unreliable criterion. Prof. BARCROFT suggests that its maximal capacity for effort is much more constant, and works out the principle of maximal activity. Briefly, we are asked to look at physiology from a new angle, and to regard it as a science based on certain characteristic principles.

The critical reader will realise that all these ideas are not new, and that others may turn out to be fallacious; he may even think that some have been omitted. The last thing one would suppose from the tone of the work, however, is that the author claims finality. It is an adventure, and the approach he has opened up will doubtless be exploited by others until by elimination a few fundamental principles are accepted. It is, moreover, a personal adventure. Running right through is the thread of the author's own experience; no attempt is made at exhaustive treatment of any subject in the modern review sense of considering every piece of work which has been done. The core of each chapter is an idea, and an arbitrary selection of evidence is made just sufficient to render this clear; it is not surprising, therefore, that the work of the Cambridge school bulks large in the arguments advanced. These are closely reasoned, often ingenious, and call upon the powers of concentration of the reader; as is to be expected, they may nearly all be applied to investigations not mentioned by the author and which must be supplied by the reader himself if he is to obtain full value from the exposition. The treatment is never heavy, and is relieved by frequent outcrops of humour and reminiscence. Intense individuality is the keynote of the style, and in places accounts for the material itself; if Prof. BARCROFT feels like writing a great deal about a single point he does so. Ten times the amount of space allotted to the kidneys is devoted to the lungs in considering the regulation of H-ion concentration, but a fascinating theory of respiration is evolved. It would not be difficult to pick out points for criticism—as for example, the treatment of Head's theory of sensation—but the whole value of the work, apart from the account of certain original investigations, is in its stimulus to thought, and criticism not directed at the main thesis is hardly valid. Although it is probably true to say that no one could read this work without acquiring new information, it should be studied by everyone interested in the evolution of physiology not for this reason, but for the sake of its orientation.

MAGNESIUM SALTS IN NEPHRITIS

THE therapeutic value of Epsom salts in nephritis was well known to the older clinicians, who used it in dropsy to remove fluid from the body. A few years ago K. D. BLACKFAN[1] recommended the administration of magnesium sulphate in cases of acute glomerular nephritis in children as a means of warding off the cerebral manifestations usually described as uræmic convulsions, which he regards as due to cerebral œdema. Very large doses were found to be necessary: at first 30 to 60 c.cm. of a their pathology sketched, their symptoms reviewed. Diagnosis and treatment are also discussed. It is good to find how adequate is the presentment in most instances, notwithstanding its enforced brevity; Dr. Pritchard shows his skill in knowing what to omit as well as what to include. At times, however, he is too brief; there are quite a number of other causes for subarachnoid hæmorrhage than aneurysmal rupture; in so-called neuromyelitis optica other paraplegic syndromes than that of "acute transverse myelitis" are possible; other pathological bases for progressive muscular atrophy of syphilitic origin than meningomyelitis exist. The conception of "end-arteries" in the brain (p. 179) needs revision. "Serous meningitis" is a better term than "otitic hydrocephalus," with which it is here made synonymous, for the former is more comprehensive than the latter.

Outline of the Cranial Nerves

By John Favill, M.D., Associate Clinical Professor of Neurology, Rush Medical College. London: Cambridge University Press. Pp. 112. 8*s*. 6*d*.

It is not easy to write a compendium of cranial nerve anatomy and physiology in small compass. The subject is intricate; tests are sometimes elaborate and cannot be made less so; some matters are still sub judice; while in regard to others conflicting views obtain. Dr. Favill's little book is so good that it is worth while pointing out one or two things that should be reconsidered in a future edition. Under the list of conditions associated at times with optic atrophy reference should also be given to oxycephaly, Friedreich's disease, amaurotic family idiocy. It is surely a mistake to put down Mongolian idiocy as a cause of optic neuritis, or Friedreich's disease as a cause of retrobulbar neuritis. The worth of Wernicke's reaction (pupillary) has been challenged more than once successfully. Under the pathology of the oculomotor nerve mention of recurrent types and their causation might be made. Ingvar's explanation of the Argyll Robertson pupil is not, we consider, the "best," since it does not explain its occurrence in tumours of the anterior colliculi. Anisocoria may also occur in lesions of the temporal lobe and this deserves note. The difference between the respective actions of atropine and cocaine on the pupil is not made altogether clear. Myasthenia should be added to the list of causes of transient diplopia. The "jelly" nystagmus of disseminated sclerosis is worth specifying. Syringomyelia is also a cause of nystagmus. Deep sensibility from ocular muscles is not conveyed by the fifth.

Despite these and other minor matters we congratulate the author on his admirable little volume, which serves a most useful and practical purpose.

Recent Advances in Pathology

Second edition. By Geoffrey Hadfield, M.D., F.R.C.P. Lond., Professor of Pathology in the University of Bristol; and Lawrence P. Garrod, M.A., M.D., B.Ch. Camb., M.R.C.P. Lond., Bacteriologist and Lecturer in Bacteriology, St. Bartholomew's Hospital. London: J. and A. Churchill. 1934. Pp. 457. 15*s*.

In the second edition of this excellent book the text has been revised and a few additions have been made. These, while not adding greatly to the bulk of the book, considerably enhance its value. In particular attention may be drawn to a section on the pituitary gland which shows clearly the general trend of recent work on this subject. The section on the digestive system includes a discussion of the different forms of anæmia; this is justified by the accumulation of evidence that certain forms of anæmia are fundamentally disorders of gastro-intestinal function. Recent observations incriminating radium as a carcinogenic agent are described in the chapter on experimental cancer research. The section on vitamins has been rewritten and brought up to date. In the neurological section a few errors are perpetuated, for example the statement that capillary hæmangioblastomas are confined to the cerebellum, and the treatment of the very difficult subject of the gliomas leaves something to be desired. In such a matter it is obvious that all exponents cannot be satisfied, but the authors have hardly recognised the large measure of agreement that exists on such aspects as are essential for teaching purposes.

The work as a whole is well up to date and provides a most useful adjunct to the ordinary text-book on pathology.

La sténose hypertrophique du pylore chez le nourisson

By J. Poucel, Surgeon to the Hospitals of Marseilles. Paris: Masson et Cie. 1934. Pp. 108. Fr.20.

This well-planned monograph on hypertrophic stenosis is a valuable contribution to the surgery of infancy. The section on ætiology and pathology of a little understood condition is well set out. Dr. Poucel, while not stressing any particular theory, inclines towards that of a sympathetic nervous system anomaly. The clinical aspect is fully described, with a vivid and accurate description of the appearances of acute starvation so often seen in pyloric stenosis. In discussing the investigation of a suspected case the importance of the blood chemistry is perhaps unduly stressed, and similarly one would hesitate to assert that every case should undergo X ray examination. In discussing the differential diagnosis between pylorospasm and true stenosis the author notes that the former condition will yield in the majority of cases to treatment by calcium chloride, belladonna, lavage, and ultra-violet ray treatment, and he wisely asserts that cases of so-called spontaneous cure are usually cases of spasm—a belief supported by those of wide experience. In the section on treatment, the importance of collaboration between physician and surgeon is well emphasised, and all will agree with the author's insistence on breast feeding where possible throughout the treatment, whether medical or surgical. It is also satisfactory to find that early operation, as soon as diagnosis is established, is strongly advocated, since only in this way can a low mortality be achieved. In the section on operative technique Dr. Poucel points out that the operation, usually associated with the name of Rammstedt, was actually first described and practised by Fredet. Nowadays, when local anæsthesia is extensively used for this operation, it seems strange to see chloroform advocated as the anæsthetic of choice, especially as the subject is not uncommonly in a toxic condition, due to starvation and gastric fermentation.

The monograph is carefully and accurately written and should certainly be studied by both the pædiatrician and the surgeon interested in children's disorders.

[1] Bull. Johns Hopkins Hosp., 1926, xxxix., 69; Jour. Amer. Med. Assoc., 1931, xcvii., 1052.

50 per cent. solution was given by the mouth or per rectum and repeated every four hours; later it was observed that a more rapid effect could be produced by the intravenous injection of a 1 per cent. solution of the anhydrous salts in doses of 10 c.cm. per kg. of body-weight or by the intramuscular injection of a 25 per cent. solution of the salt in doses of 0·2 to 0·4 c.cm. per kg. In a recent paper, however, A. D. HIRSCHFELDER [2] points out that the use of magnesium sulphate in nephritis is not without danger, especially if it is given by the mouth when the increase in the magnesium content of the plasma cannot be controlled. In a normal organism the administration of magnesium sulphate is followed by rapid excretion of the ingested salt through the kidneys and the plasma magnesium shows only a slight rise, the maximum increase being 0·4 mg. per 100 c.cm. of plasma. But in conditions of impaired renal efficiency, whether induced experimentally in animals or present in man, the excretion of magnesium salts is greatly delayed, and the administration of Epsom salts per os therefore leads to a tremendous and rapid rise in the plasma magnesium. In animals with experimentally induced renal insufficiency this may be sufficient to raise the level from the normal of 2 mg. per 100 c.cm. of plasma to the neighbourhood of 17 mg., when coma sets in. In nephritic patients an ordinary purgative dose of Epsom salts may raise the magnesium content to 10 mg. or even higher, and a number of patients showed a decidedly increased drowsiness or even a light coma accompanying the increase in plasma magnesium. It is pointed out that a condition easily mistaken for uræmic coma can be induced sometimes in nephritic patients by Epsom salts purgation.

When the magnesium content of the plasma was determined in patients with acute, subacute, and chronic glomerulonephritis before and after the administration of Epsom salts, it was found that there were two distinct groups: those with an abnormally high and those with an abnormally low magnesium content. The majority of the patients (nine cases) showed a slightly higher level—3 to 5 mg. of magnesium in 100 c.cm. of plasma—but in three the increase in the magnesium content was considerable (from 9 to 13 mg.). In such cases therefore the use of sodium sulphate as a purgative is preferable to Epsom salts. In a smaller group of four patients the magnesium content of the plasma was reduced to half the normal level, and there were general muscular twitchings. These were abolished by a purgative dose of Epsom salts which also raised the magnesium level considerably, but not to the same high figures as in the patients with a high plasma magnesium. A low plasma magnesium associated with general muscular twitchings was observed also in six patients suffering from other conditions such as parathyroid deficiency, eclampsia, and epilepsy. In these patients also the muscular twitchings were abolished by a purgative dose of Epsom salts. It will be seen therefore that there is a clinical syndrome of high plasma magnesium accompanied by drowsiness or coma and another one of low plasma magnesium accompanied by muscular twitchings or convulsions.

The observation that nephritis in man may be associated with an abnormally high or an abnormally low magnesium content of the plasma gains additional interest from the fact discovered by W. CRAMER [3] that it is possible to produce experimentally an extensive glomerulonephritis by a diet deficient in magnesium salts. This effect is due to an imbalance between calcium and magnesium ions, known to be biological antagonists, since the nephritis fails to appear if both magnesium and calcium salts are omitted from the diet. This suggests that the Ca : Mg. ratio in the plasma is of more importance for the maintenance of renal efficiency than the absolute amounts of either magnesium alone or calcium alone and that investigations along these lines may throw fresh light on the problem of nephritis.

THE LONDON CHILD

To ratepayers who have watched a little wryly the progressive policy of the London County Council with regard to public health, Sir FREDERICK MENZIES's latest report [4] as school medical officer should prove particularly reassuring. The direction of the energies of the school medical service toward the prevention and control not only of disease but of the factors tending to defective physical development should do much to reconcile those whose money is spent "by somebody else for somebody else."

The eldest groups of children with whom the report is concerned are a product of the post-war years, the "leaving" class having been born in 1919 and 1920, at a time when large numbers of able-bodied men had been demobilised and the birth-rate was rising rapidly. Their superior physique as compared with the children born a little earlier is perhaps attributable not only to better nurture but also to the fact that a considerable proportion of wartime babies belonged to fathers physically unfit for military service. While it is hard to say whether there is actually an increase in stature in the present as compared with earlier generations, a comparison of the average figures for height and weight, obtained by Dr. R. H. SIMPSON in his survey of the 10-year-old group of boys and girls in 1933, seems to show a significant gain over corresponding figures for the whole of London between 1902 and 1907. Similarly a comparison of the average height of recent secondary school boys between the ages of 14 and 15½ with Roberts's tables (compiled about 50 years ago from artisans, public school boys, and cadets) show an increase of about 1 inch at each age. In the Council's residential schools and homes a new standard (provisional) dietary came into force in March, 1932, and Dr. W. P. SHELDON has compared the weights and heights of children at the time the new dietary was introduced with the weights and heights of children of the same age who have had it for a year. In 10 out of 13 age-groups the advantage in both weight and height lies with the children on the new dietary, and it is found that the actual average increases in each age-group considerably exceed the expected increase as calculated from the average weights of London elementary school-children of different ages. The improved dietary is given in detail in the report. In the ordinary school the continued high incidence of unemployment and economic depression has made the provision of "meals" (dinners with 25 g. of protein and 750 calories, milk, and cod-liver oil and malt) increasingly necessary. The school care committee is required to "place upon the feeding list every necessitous case requiring additional nourishment in order to profit by the education provided," and 4½ million meals, of which nearly 2 million were paid for out of the rates, were provided in 1932–33. One is inevitably reminded of the savage description of the modern world—

> "Science finds out ingenious ways to kill
> Strong men, and keep alive the weak and ill
> That these a sickly progeny may breed
> Too poor to tax, too numerous to feed"

and can only hope that the future will justify the attempts now being made to keep the standard of living for all children at a level that makes healthy growth and development possible.

The rôle of the physically defective schools could usefully be studied by most medical men who are unfamiliar with their organisation. Dr. GERALD SLOT has carried out an inquiry into the causes of absence from these schools, and finds that children are often excluded by medical certificate because of the very diseases that the schools are designed to treat. Usually more rest and warmth can be had at these schools than at home, and not infrequently the medical certificate simply provides facilities for playing in the street or helping with the housework. Additional reasons for non-attendance include missing the ambulance (which may not be able to enter the alley in which the child lives, and must be awaited at "points" in the street), subconscious malingering, and over-anxiety on the part of parents; whilst genuine illness, requiring hospital or convalescent treatment, is of course commoner than in normal children. The work nowadays called child guidance is not directly undertaken by the Council as an education authority, but a clinic is available through the mental hospitals service at the Maudesley Hospital where psychotherapy is available for school-children and others. Here, and at other centres, including the London Child Guidance Clinic and the East London Clinic, the attendances are allowed to be counted as attendances at school. Except at the Maudsley, however, the provision of child guidance is by voluntary hospitals and associations. Open-air education is provided for tuberculous cases in six open-air day schools, accommodating a total of 568 children, and there are nine such schools for non-tuberculous children (1627). In addition there are seven convalescent camp schools and 209 open-air classes in playgrounds and parks. Despite the difficulties of the London climate, there is no question that these schools are filling a real need and are extremely successful with selected cases, especially those of chronic lung infection.

The report as a whole gives evidence of activity and expansion in almost all the fields covered, and it is impossible not to be impressed with the spirit of optimism in which it is conceived and written.

ANNOTATIONS

BRITISH EMPIRE CANCER CAMPAIGN

THE eleventh annual report of the British Empire Cancer Campaign, a substantial volume of 220 pages, contains reports from 30 institutions or individual workers who have been subsidised by the Campaign. At the annual general meeting held at the House of Lords on July 9th, Lord Reading presiding, Mr. Cecil Rowntree said that the report afforded convincing proof that the purposes for which the Campaign was founded were being fulfilled. The work carried out in the different centres differs necessarily both in its extent and in its value, and it is only intended to indicate here some of the more important advances made. A group of research workers at the Cancer Hospital, under the direction of Prof. E. L. Kennaway, some years ago isolated from tar substances having the power to induce cancer. They then proceeded to prepare synthetically a large number of chemically pure organic substances and to test their carcinogenic power. This work, to which we have repeatedly drawn attention, led to the surprising discovery that some of these carcinogenic substances were chemically closely allied to substances normally present in the cells, such as the sterols and the chemically related bile acids, which are probably formed from sterols This suggested the possibility that the cells of the body, when placed under abnormal conditions, might be able to form, as abnormal metabolites, substances which are carcinogenic. In order to test this question Mr. J. W. Cook, M.Sc., and Mr. G. A. D. Haslewood have taken as their starting point one of the bile acids and have prepared from it an actively carcinogenic substance. This transformation was effected by a series of chemical changes of exactly the same nature as those which commonly occur in the body. The chain of evidence is therefore nearing completion that carcinogenic substances can be formed by the cells in vivo. The hormone œstrin, one of the substances normally present in the body, is also chemically closely allied to the sterols and to some of the synthetic organic substances capable of inducing cancer. Investigations carried out in conjunction with Prof. E. C. Dodds have shown that some of these synthetic carcinogenic substances have also the power to induce œstrus, although in comparison with œstrin larger amounts are required. But not all carcinogenic substances can produce œstrus, and œstrin itself is not carcinogenic.

Another interesting line of investigation was initiated a few years ago by Dr. P. R. Peacock at Glasgow. He showed that it was possible to induce with comparative ease sarcomata in fowls by the injection of tar or of pure organic carcinogenic substances. Some of these tumours could be propagated, but only by the transplantation of living cells, and not by the inoculation of a cell-free tumour extract. This seemed to establish a difference of ætiological importance between the malignant growths which arise in fowls and mammals including man in response to chemical substances on the one hand, and on the other the group of filtrable tumours discovered by Rous which can be propagated by an "extrinsic agent" or "virus." Prof. E. Mellanby appears to have had a similar experience but the experimental details of his work have not yet been published. Prof. J. McIntosh now states that he has succeeded in producing in fowls by tar a number of sarcomata, three of which proved to be filtrable, and a similar result is reported by Dr. A. Haddow from Edinburgh. These results are a strong argument in support of the view that the filtrable fowl tumours represent true malignant neoplasms, and that they should not be set aside as an atypical form of malignancy with an entirely different ætiology. In the introductory summary to the report the conclusion is drawn from these findings that the behaviour of the filtrable fowl tumours is due to some characteristic property peculiar to fowl cells; that, however, is not the only possible explanation.

In Leeds Prof. R. B. Passey has begun a reinvestigation of the classical experiments of Fibiger on spiroptera cancer, in which the experimental production of cancer was demonstrated for the first time. Prof. Passey's work indicates that other subsidiary factors, not suspected at the time by Fibiger, play a part in the process. Dr. R. E. Havard and Dr. Sylvia Dickenson have tested the truth of the statement frequently made that the blood of patients suffering from cancer is abnormally alkaline. Using arterial blood and an exact physical method they failed to find any change. Dr. J. W. Orr has carried out experiments showing that fibrosis of the dermis facilitates [illegible] resumably because it interferes [illegible] y. The action of radium and X rays has been investigated in a number of centres, both from the experimental and from the clinical side, notably at St. Bartholomew's Hospital, the Westminster Hospital, the Mount Vernon Hospital, the Strangeways Research Laboratory, and the Christie Hospital and Holt Radium Institute in Manchester. It is noteworthy that the question of changes in the leucocyte count following irradiation, on which we commented last year, has been reinvestigated in the Manchester centre, and as a result two points are emphasised: (1) there is a lymphopenia in patients treated by radium which increases with the dose; (2) blood counts repeated at least once a month have been found of definite value in keeping a check on the health of the staff engaged in radiotherapeutic work.

The eleventh report of the Campaign is commendably free from exaggeration of the value of the results obtained, nor do these need exaggeration. The report represents a real advance both in our understanding of the ætiology and in our efforts towards the treatment of the disease, and is the best possible argument for the continued support of the work by the general public for whose benefit it is done.

RADICAL SURGERY OF THE MAXILLARY ANTRUM

IN the surgical treatment of suppuration of the maxillary antrum rhinologists in this country of recent years have favoured the intranasal operation, by which an aperture is made in the antronasal wall large enough to remain open permanently and the drainage thus established is relied on to effect a cure. The Caldwell-Luc operation, which exposes the antral cavity through its anterior wall as a preliminary before making the opening into the naris, is usually reserved for the more intractable cases and for those in which a portion of tooth or of dead bone is lying in the antrum, or in which there is definite polyposis. Dr. Edward F. Ziegelman,[1] of San Francisco is now advocating the latter method, together with removal of the entire mucous membrane lining the cavity and of the anterior ethmoidal cells, also in all those cases where there is disease in the neighbourhood of the natural ostium. He strongly objects, however, to the usual transverse incision with elevation of the premaxillary soft structures from the bone, and makes an inverted T-shaped incision of which the vertical branch runs obliquely upwards and outwards parallel to the fibres of the facial muscles. Since these muscles run in the upper lip, and the incision is placed deeply to this, it is difficult to see how it can be a matter of any great importance. The most noteworthy part of his communication is concerned with anæsthesia for the operation. He prefers a local anæsthetic and considers that nerve-blocking is the ideal method. This he produces by injection through the external aspect of the face, passing a long needle into the neighbourhood of Meckel's ganglion in the spheno-maxillary fossa. The needle is inserted at a point on the inferior margin of the zygoma two-fingers' breadth external to the outer bony angle of the orbit, and directed towards the external angle of the opposite orbit to a depth of approximately 7 cm.; 3 c.cm. of 1 per cent. novocain are injected. As the injection does not always catch the main trunk in its entirety, a second injection of 2 c.cm. is made into the infra-orbital nerve at its exit from the foramen. Since the anterior ethmoidal cells often have to be opened during the operation, these are anæsthetised by a pack of 5 per cent. cocaine beneath the middle and inferior turbinals, or by injection of 1 c.cm. of the novocain solution into the region of the anterior ethmoid foramen through the skin at the inner angle of the orbit. Dr. Ziegelman mentions that the patient often objects to the insertion of the needle into the spheno-maxillary fossa by way of the external surface; such objections, which are hardly surprising, may be met by injection via the posterior palatine canal by means of a curved needle inserted through the mouth. In addition to the novocain injections, the patient is given, two hours before operation, grs. 10 of one of the barbiturate salts by the mouth, and an hour later a hypodermic injection of morphine sulphate gr. ¼ with scopolamine gr. 1/200. Probably surgeons in this country will prefer a general anæsthetic in cases where it is not definitely contraindicated.

PUBLIC HEALTH IN THE IRISH FREE STATE

AN extensive account of the activities of the Departments of Local Government and Public Health in the Irish Free State is given in the 1932–33 report of the Minister.[2] Sanitary surveys, it is reported, were carried out by the medical inspectors of the department in 37 different areas (the majority urban), and where serious defects in the sanitary administration were discovered they were brought to the notice of the local authority, special attention being paid to water-supplies and sewerage systems. Despite the constant intercourse with England and Wales the last appearance of small-pox in the country was, it is oted, as long ago as November, 1923, and no fatal ase of the disease has been registered since 1907. On he other hand, 30 cases of typhus, with 8 deaths, ere recorded in 1932, whereas in England and Wales here were only 9 deaths from this cause in the whole f the ten years 1923–1932. Twenty-five of the 30 ases occurred in Kerry County and 22 from three amilies affected in an outbreak in November. A eneral campaign of delousing and disinfection was instituted and no further extension took place. Notifications and mortality from diphtheria both showed in 1932 an appreciable rise over the figures of the previous year, and immunisation schemes have been organised in numerous areas. In Cork County Borough, where a prolonged epidemic has been experienced, nearly 7000 children were immunised between 1929 and 1932, and the high record of 626 cases in 1930 fell to 282 cases in 1931, and to 90 cases in 1932. The case-mortality rate, however, has not kept pace with the reduction in notifications and was as high as 19 per cent. in 1932, though, it is important to note, no immunised child died. With the decline in the incidence of the disease in Cork there was observed a marked falling off in the number of children brought to the immunisation clinic, so that the consequent increase in the number of non-immunised children may provide a new field for the extension of the disease.

[2] P. No. 1151. 1934. 2s. 6d. net.

An unsatisfactory feature of the registration returns for 1932 was a slight rise in the infant mortality-rate to 72 per 1000 births, chiefly attributable to an increased mortality from diarrhœa and enteritis and pneumonia. Nursing associations to attend to the health of the infant and young children, as well as of expectant and nursing mothers, are being organised, and with the help of the sweepstake surplus a number of such associations were launched during the year. Rapid development has also been made in the school medical inspection arrangements which in 1929 covered only 146,000 children and in 1932 extended to 378,000, or 75 per cent. of the elementary school population. Many of the medical officers comment upon the incidence of malnutrition, and in June, 1932, the Dáil voted £100,000 to assist local authorities to provide free milk and so ensure that during the period of economic distress children in the poorest families should not suffer from a lack of food essential to their healthy growth and nourishment. In spite of the economic position a new low record was registered for tuberculosis mortality, though the crude death-rate of 1·24 per 1000 is considerably higher than that in England and Wales. Other sections of the report are devoted to local finance and administration, to housing, public assistance, and to roads.

SILICOSIS IN THE SOUTH WALES MINER

Few diseases require a more comprehensive survey before diagnosis than silicosis. In the June issue of the *Practitioner* Dr. A. J. Amor and Dr. R. G. Prosser Evans made a brief assessment of the various factors of this disease as it affects the South Wales coal-miner. Although they admit that W. R. Jones's recent suggestion of sericite as a causative factor needs careful consideration, they do not appear to regard the evidence as it stands at present as convincing. In dealing with the all-important matter of X ray examination, the authors stress the necessity for accurate standardisation of films, especially the exact centring of the patient, a speed of exposure which will avoid blurring, and standard developing. A pre-X ray stage of the disease is recognised in addition to the first, second, and third stages of the shadowing on the film. Details are also given of a method of chemical examination which they adopt in investigating the silicotic lung after removal from the cadaver. The lung is first X rayed with a soft tube and areas which appear to be suspicious in the film are selected for pathological examination, together with immediately adjacent areas. The portions thus removed are divided into two so that as far as possible macroscopically identical portions can be used both for section work and for estimation of silica content. Whilst recognising that this method is open to some criticism, the authors believe that it enables a fairly full and accurate description of the pathological condition to be made. Chemical determinations of silica content are considered to be of value and importance when assessed together with the other diagnostic factors; but taken alone they are, in the opinion of the authors, of little use because a high silica content may be found in lung tissue in which no gross lesion is present. Two methods of silica determination are used: (1) the modification of the colorimetric method of Isaac; and (2) the gravimetric method of Treadwell and Hall. A representative series of determinations of silica content from six areas of a lung are given in a table, showing a range from 16·32 to 28·15 per cent. in two upper lobe portions.

ORGANISATION IN THE OPERATING THEATRE

Dr. Eugene H. Pool, of New York, a surgical teacher of great experience, writing of the part played by the nurse in the organisation of the operating theatre, says "her coöperation, skill and goodwill are usually taken for granted." It is substantially true that where the work of the nursing staff is efficient its importance to the success of the operation is unrealised, or at least forgotten, by the surgeon—until her coöperation breaks down in some detail. If this detail is of sufficient importance—as, for instance, a miscount of the swabs in an abdominal operation, or a muddle over the contents of the bottles on the anæsthetic table—the surgeon is made sharply aware of the degree of responsibility he is delegating to the nursing staff. Such an incident may stimulate his interest in the manner and material of the instruction given to the theatre nurse; but, for the most part, the responsibility for such instruction is left entirely in the hands of the theatre sister, who is not necessarily appointed to her post on a definite knowledge of her powers of training those working under her. Dr. Pool's remark, which we have quoted above, occurs in a foreword to the revised edition of a book[1] by Prof. Henry C. Falk, F.A.C.S. The basis of the book is a course of lectures given to the theatre nurses of the French Hospital of New York City. The book has been brought up to date and made as comprehensive as possible. Any doctor unfamilar with the amount of detail and specialised knowledge involved in the efficient conduct of a theatre behind the scenes would do well to look through this book, which contains many suggestions for increased efficiency.

In organising the work of an operating theatre, the first essential is a clear understanding about the delegation of responsibility. On the surgeon rests the responsibility for the patient's life. It is for this reason that, during the conduct of the operation, he must receive active and willing coöperation from everyone assisting him. All his orders and requests—reasonable or unreasonable as they may appear to others—must be obeyed at once. This is a point of view which is obvious when stated, but is not always implicit in the attitude of the nursing staff, probably because the reason behind it is imperfectly realised. The surgeon, in his turn, delegates responsibility to the theatre sister, and it is really essential that he should be clear in his mind at all times for just what details he is making her responsible. The sterilisation of instruments, gloves, and linen is arranged by her without any sort of supervision. In most theatres the sister looks after instruments and swabs. The surgeon should be perfectly clear as to whether he is making her responsible to him for the count at the end of an operation; he should also make it clear to the sister whether she is being held responsible. There seems no doubt that the final responsibility rests with the surgeon, but it is essential that someone quick-witted and perfectly reliable, not to say honest, should be present to do the actual business of counting, and to report to him the result. The best person is probably the theatre sister because, being constantly in the theatre and having control of the probationer nurses, she can work out a simple and efficient scheme which is rigidly adhered to at every operation.

---

[1] Operating Room Procedure for Nurses and Internes. London: G. P. Putnam's Sons. 1934. Pp. 413. 12s. 6d.

The next important cog in the wheel is the staff nurse. It would result in more efficiency and less worry if this post, in small hospitals as well as in large, could be a semi-permanent one, and if only those nurses were appointed to it who had had special training in theatre technique, and who had proved their ability. The staff nurse has to take charge in the absence of the theatre sister, and this should imply ability to deal with any type of emergency. There are two details of operating-room procedure in which nurses appear to be specially liable to fail. One is moving the patient into one of the special positions, such as the kidney position or the lithotomy position; the other is the adjustment of the operating table. Familiarity with all the mechanism and vagaries of this table should be incumbent on every member of the theatre staff. These are, or should be, matters of regular drill. The theatre sister should not only be efficient herself, but capable of calling forth efficiency in others. It is no testimony to her capabilities that the progress of an operation should be less smooth when she is away than when she is there.

CANCER OF THE BREAST

MANY records have been made of end-results in mammary cancer, but so far few satisfactory deductions can be drawn from them. For this there may be several reasons, such as the variety of treatment adopted at different clinics, the absence of definition of the stage of tumour growth at the time of treatment, and the lack of classification in homogeneous groups. Classification for prognosis in mammary cancer seems indeed a fundamental difficulty. It might be claimed that some objective uniform plan of grouping, such as Jüngling's, is likely to be accurate and suitable for statistical purposes, but any clinical classification without microscopical check is liable to err in regard to axillary involvement. A histological classification, based on the examination of small areas of malignant tissue without reference to the morbid anatomy of the tumour as a whole, is also unhelpful. Uncertainty about the variables which should be selected as the basis of statistical analysis makes it hard to compare figures from different clinics, and probably underlies the variations in survival-rates.

A study by R. B. Greenough and G. W. Taylor,[1] the fourth of a series of reports on end-results in cancer of the breast treated at the Massachusetts General Hospital, is instructive, despite the comparatively small number of cases, because it is based on a more or less uniform treatment and grading at the same centre. Their figures add a comment on various problems; they show for example the influence of age, by emphasising the relatively greater gravity of the disease in younger women, but suggest that the duration of the tumour has only a limited value in group prognosis. For the pathologist, the authors' readjustment of view with regard to histological classification and the degree of malignancy is especially interesting. To their earlier criteria of cellular architecture and cytological character they have added an additional factor, "infiltration," which they regard as a marked step in de-differentiation and thus an indication of high malignancy. But infiltration appears to be a sign not of heightened malignancy but primarily of extension into the surrounding tissues, with greater likelihood of lymphatic vessel invasion—an almost inevitable sequence in advanced cases. This in itself would account for the less hopeful outlook in cases where this "factor" is much in evidence. Axillary involvement was present at the time of operation in 11 per cent. of their Grade I. cases, in 70 per cent. of Grade II., and in 90 per cent. of Grade III., a finding which suggests that infiltration counted as a weighty factor in prognosis.

In considering the treatment of malignant mammary tumours, Greenough and Taylor again emphasise the necessity for the complete radical operation where this is possible: where the diagnosis is in doubt —and this is usually in very early cases—they find no reason to suppose that exploratory incision is prejudicial to cure, provided that facilities for histological examination and the completion of the radical operation, if indicated, are available. Prophylactic X ray therapy was employed, in addition to operation, in most of their more recent cases, and results in these support those from other centres in giving a higher proportion of five-year cures than where no irradiation was given. They hold that increase in the percentage of five-year cures, and avoidance of many of the deaths occurring within six months of operation, may be expected from greater care in estimati[illegible] that palliative irradiation is [illegible] of mortality from cancer of the breast over all cases depends, as has often been pointed out, on the readiness of the profession and the public to take a serious view of any mammary abnormality; though in this connexion it is noteworthy that the percentage operability has remained almost constant for Greenough's series of reports on cases treated since 1894.

ACUTE PULMONARY ŒDEMA

ACUTE pulmonary œdema occurring in heart disease is in this country generally regarded as due to a sudden left ventricular failure leading to congestion and œdema in the lungs. A different view is held by S. Wassermann,[1] who considers it due to a reflex, usually initiated from the aorta or coronary artery, in the cardio-pulmonary portion of the vegetative nervous system, leading to spasm of the pulmonary capillaries. He finds that the condition can be relieved or completely suppressed by pressure on the carotid sinus, and that the attacks, which appear for the most part spontaneously, are accompanied by an increase in pulse-rate and blood pressure and by certain other symptoms which are held to be evidence of sympathetic irritation. Carotid sinus pressure is effective in treatment, it is supposed, principally by producing a counteracting vasodilator reflex on the pulmonary capillaries. Cardiac asthma—a condition not sharply to be distinguished from pulmonary œdema—and angina pectoris we know generally to be associated with a gross pathology similar to that of pulmonary œdema, and Wassermann believes these functional disturbances also to be the result of reflexes, the difference lying in the site of action of the effector, this being the bronchi in cardiac asthma, and the coronary artery in angina. The efficacy of the usual methods of treatment for these syndromes is considered to be better explained on the basis of abnormal reflex action than by the conventional views.

RESEARCH AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE impetus towards surgical research at or in connexion with the Royal College of Surgeons of England has gained force during the last year. The annual report on the museum, research laboratories, and the Buckston Browne Surgical Research Farm records many alterations and advances in organisation and even more constructive plans for the future. The additions to the museum during the year will be on view in a special room for the next three weeks, and are better visited than described. The director of research, Prof. J. Beattie, summarises the investigations actually in progress.

Sir Charles Ballance is recording by cinematography the results of sympathetic-peripheral nerve anastomosis in animals; Mr. Winsbury-White has continued his investigations into the spread of pelvic inflammation; Mr. Mortimer Woolff is attempting to produce intestinal diverticula experimentally: Lieut.-Col. E. P. Argyle has shown that the essential lesion in "roaring" horses is a peripheral neuritis in the left recurrent laryngeal nerve. A field at Downe is being put at the disposal of Dr. R. J. V. Pulvertaft who asked for accommodation for ponies and horses in order to investigate the possibility of producing a serum which would retard the growth of secondary carcinomatous deposits in man. Mr. J. H. Thompson's extracts of the anti-growth factor of parathyroid glands have been found to retard the growth of small, but not of large, tumours in mice. At Downe Dr. D. Slome and Mr. L. F. O'Shaughnessy have been working on surgical shock, Mr. G. C. Knight on the ætiology of achalasia of the cardia, and Dr. Rupert A. Willis on a structural study of teratomata. In connexion with this work over 1000 microscopical sections have been made by Mrs. Willis, and composite maps have been drawn, enabling visualisation of the distribution and relationships of the tissue components of the tumours. The conclusions reached are that the arrangement of the tissues is not wholly fortuitous, that metaplastic changes are of frequent occurrence, and that coöperation between embryologists and morbid anatomists in the minute study of teratomata should lead to important results.

The provision of extended laboratory accommodation for research in the college itself, apart from the farm laboratories at Downe, is being considered, and various schemes to this end are under discussion.

VENTRICULOGRAPHY IN DIAGNOSIS

THE reliance placed on ventriculography as a means of localising brain tumours varies considerably in the practice of different surgeons. Its value is demonstrated, however, in an analysis, by Cobb Pilcher and Hugh M. Wilson,[1] of 97 cases of verified intracranial tumours in which it was applied. The results of this analysis are arranged in three groups. A positive result is recorded when the information obtained was of "localising" or "lateralising" value. The latter term is used to denote evidence that defines the hemisphere in which the tumour is situated but not the lobe involved. A second group is labelled as "indeterminate" and the third "misleading." In the 97 cases a positive result was obtained in 79 instances, an indeterminate in 7 and a misleading in 11. Twelve of the positive results were of the lateralising variety and it is noteworthy that 10 of these were associated with tumours of the temporal lobe. This may be accounted for by the difficulty in getting complete filling of the ventricular system and hence a failure to visualise the whole of the inferior horn. These figures should impress the sceptical with the value of this test in diagnosis. Pilcher and Wilson's conclusion that ventriculography should not be relied upon as a sole means to diagnosis but used as an adjunct to this end is in the best tradition of medical practice.

INTERNATIONAL CONGRESS OF GASTRO-ENTEROLOGY

MANY of the clinical and pathological questions arising out of the diagnosis and treatment of the conditions covered by the term Gastro-Enterology have been gone into before medical séances and congresses, but now an international convention has been planned, to be held in Brussels in the first week of August next year, at which time a universal exhibition will be in progress in the city. Dr. J. Schoemaker will be the president, and a strong local committee has been formed. A division of the subject into sections has been arranged, the coöperation being already secured of leading men in various countries. Those who desire to participate in the debates or to be present at the meeting are asked to communicate with the secretary-general of the Congress, Dr. G. Brohée, 64, Rue de la Concorde, Brussels.

THE SURGERY OF THE ŒSOPHAGUS

A REMARKABLE communication by T. Ohsawa[1] records numerous experiments on animals and operations on man. In one respect his teaching is heterodox: he refuses to employ positive-pressure anæsthesia. Elsewhere it is based on established principles, but the results are unusually good. Though no success was obtained in tumours of the upper reaches of the œsophagus, the successes claimed for those situated below the lung root—some of these invaded the cardiac end of the stomach—are very striking. Healing was secured in 10 out of 19 cases of this type, and in these patients natural swallowing was restored either by end-to-end anastomosis of the œsophagus or by œsophagoenterostomy. To these achievements three factors appear to have contributed: first, Ohsawa recognises that the blood-supply of the lower œsophagus is largely derived from the bronchial arteries, so that a very limited resection is less likely to succeed than one that extends almost up to the level of the bifurcation of the trachea; secondly, he makes use of the large omental graft[2]; and thirdly, he employs free exposure—opening both abdomen and left pleural cavity in all the operations. Sometimes he begins with a left thoracotomy and then enters the abdomen by incision of the diaphragm; in other cases laparotomy is first performed and after section of the costal arch (in the manner of Marwedel) access is gained to the left pleura by incision of the diaphragm from below. In one case of innocent tumour of the œsophagus (myoma) operation was performed with success by [illegible] route. A similar method is [illegible], and he records 12 successful [illegible] type. In a resistant case of simple œsophageal stricture an antethoracic œsophagoplasty was successfully carried out, but most cases responded to dilatation. Many patients suffering from cardiospasm were treated either by œsophagogastrostomy or by the usual plastic operation at the cardia.

[2] The value of this graft as a means of controlling operative infection in the chest was discussed by M O'Shaughnessy in a Hunterian lecture for 1933.

It is clear that, brilliant as is this record, the difficulties of œsophageal surgery are not yet overcome; nevertheless Ohsawa's work is in itself enough to justify further clinical and experimental research. It is significant that the results of operations on the dog were far inferior to those obtained in man—the difficulties of nursing and the recognition of post-operative complications are very great in animal surgery. But it was only the application of the knowledge gained in these experiments that enabled him to do the valuable work he now describes.

MEDICINE AND POLITICS

THE medical school, with its long and continuous tradition, is much older than anything else in education, said Dr. Walter Elliot, Minister of Agriculture, in his address to London Hospital students last Tuesday. Other branches of education are subject to inroads by every form of crank: in the words of Shaw, "He who can, does; he who cannot, teaches." But this is not true of medicine, where the great masters are also great teachers and the student learns not so much from what a man says as from what he does. In politics to-day, he continued, we are looking towards men of education, and the biological training of the medical student is not less valuable than the classical training of the past. Indeed in present circumstances it may be still more valuable: for the Age of Reason is past, and the Age of Unreason is upon us; the Age of Logic is defeated and the Age of Race Consciousness is victorious. "You will have to grapple," he said, "with that new heresy"—with the "pushing of biological catchwords to the verge of insanity" which is wrecking countries to-day. And as trained men confronted with these opinions and situations the former medical student should remember the long international tradition behind him. "The Oath of Hippocrates is an oath of sanity."

A MEMORANDUM has been issued from the Ministry of Health furnishing information as to measures which should be taken for collecting rain-water for domestic purposes. During many past weeks no procedures for the collection and storage of rain-water would have had any result, but it is timely of the Ministry to remind the public that, when the rain does come, all possible pains should be taken to preserve every drop for future distribution. The memorandum points to the neglect prevalent in the collection of rain-water on roof areas, as proved by the wise employment of this supply in many districts, notably in East Anglia, where the inhabitants have for generations depended on rain collected from their roofs for drinking and culinary purposes. This, of course, is only possible where there is little or no industrial pollution. Precise instructions are given by the Ministry as to the storage capacity required and as to price and construction of receptacles. The memorandum can be obtained for 1*d.* from any bookseller.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Vice-Admiral Sir Reginald St. G. S. Bond is placed on retd. list.

Surg. Rear-Admiral R. W. B. Hall is granted the rank of Surg. Vice-Admiral.

Surg. Capts. T. B. Shaw and N. S. Meiklejohn to be Surg. Rear-Admirals and are placed on the retd. list.

Surg. Capt. B. P. Pick to be Surg. Rear-Admiral.

Surg. Comdr. to Surg. Capt.: K. H. Hole, J. G. Danson, J. P. Shorten, H. M. Whelan, and R. F. P. Cory.

Surg. Lt.-Comdr. M. B. Devane to be Surg. Comdr.

B. S. Lewis to be Surg. Lt.

The following appointments have been notified: Surg. Capt. E. MacEwan to *Drake* for R.N.B., Devonport. Surg. Comdrs. M. B. Devane to *Renown*; R. Buddle to *Pembroke* for R.N.B., Chatham; W. A. Jolliffe to *Victory* for R.N.B.; and A. C. V. Green to *Dolphin*.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Comdr. A. G. L. Reade is placed on the retd. list with rank of Surg. Capt.

Surg. Lt.-Comdrs. G. A. Clark and C. C. Elliott to be Surg. Comdrs.

ROYAL ARMY MEDICAL CORPS

To be Bt.-Cols.: Lt.-Cols. W. B. Purdon and F. Casement.

To be Bt. Lt.-Cols.: Majs. J. G. Gill and W. H. Hartgill.

Maj. E. P. Allman Smith to be Lt.-Col.

Maj. E. C. Stoney, Reg. Army Res. of Off., relinquishes his appt. under Art. 520 (*b*), Royal Warrant for Pay and Promotion, 1931.

Lt. T. McG. McNie to be Capt.

Maj. (Temp. Commn.) E. K. Campbell relinquishes his commn. and retains the rank of Maj.

Lt. (on prob.) R. S. Vine is secd.

CAVALRY—LIFE GUARDS

Surg. Lt.-Col. E. J. H. Luxmoore, having attained the age for retirement, is placed on retd. pay.

Lt.-Col. E. A. Strachan, from R.A.M.C., to be Surg. Lt.-Col.

ARMY DENTAL CORPS

R. H. Green to be Lt. (on prob.).

TERRITORIAL ARMY

Capt. J. C. Andrews resigns his commn.

Lt. M. C. Hounsfield resigns his commn.

Lts. D. M. Dunlop, A. S. Henderson, I. G. W. Hill, J. A. Matheson, and F. H. Taylor to be Capts.

A. C. Armstrong, D. Campbell, and J. T. Watkins to be Lts.

ROYAL AIR FORCE

The undermentioned promotions are made: Wing Comdrs. to be Group Capts.: F. C. Cowtan, W. A. S. Duck, and A. E. Panter.

Squadron Leaders to be Wing Comdrs.: J. T. T. Forbes, J. Kyle, A. F. Rook, E. A. Lumley, W. G. L. Wambeek, and T. C. St. C. Morton.

Flight-Lt. (Hon. Squadron Leader) to be Hon. Wing Comdr.: J. Valerio.

MENTIONED IN DESPATCHES

For distinguished services in connexion with the operations against the Upper Mohmands, July-October last year, the names of Col. E. W. C. Bradfield, I.M.S., Asst.-Director of Medical Servics, Peshawar District, and of Maj. F. R. H. Mollan, R.A.M.C., and Maj. A. E. Richmond, R.A.M.C., have been brought to the notice of the Commander-in-Chief in India, H. E. Field-Marshal Sir Philip Chetwode.

COLONIAL MEDICAL SERVICE

Dr. E. M. Astwood has been appointed Medical Superintendent to King Edward VII. Hospital, Bermuda, and Dr. C. J. Fournier, Medical Officer, Bermuda. Dr. W. Hughes has been appointed Medical Officer in the Federated Malay States. Dr. J. C. J. Callanan has been promoted Senior Medical Officer, Kenya, and Dr. A. T. Kuriyan, Provincial Surgeon, Ceylon.

PROGNOSIS

A Series of Signed Articles contributed by invitation

X.—PROGNOSIS OF RAYNAUD'S DISEASE

SINCE it is impossible to foretell the fate of any patient until his disease has been identified, the problems of diagnosis should have no place in an article devoted to prognosis. When dealing with Raynaud's disease, however, it is necessary to refer to two circulatory disorders which, while mimicking its manifestations run a very different clinical course.

DIFFERENTIAL DIAGNOSIS

The first is the complaint commonly referred to as "dead fingers," in which some or all of the digits when exposed to a cold and damp atmosphere assume a waxen pallor. There is frequently an hereditary element, a daughter being particularly likely to inherit the disorder from her father. The fingers never become blue, there is little or no pain, and the main complaint is of numbness, and of the unpleasant appearance of the fingers. In spite of the apparently complete arrest of the circulation from time to time, ulceration or gangrene of the fingers never occurs. Chalky deposits may form in the subcutaneous tissue as a result of ischæmia, but as this is a very rare complication, "dead fingers" need never cause anxiety. Though Raynaud included such cases in his original treatise, they are now regarded as a separate clinical group.

Secondly, in certain cases of primary structural disease of the arteries, cyanosis of the digits may occur as a result of exposure to cold, and this may lead to an error in diagnosis. The earlier stages of thrombo-angiitis obliterans of the vessels of the upper extremity may resemble Raynaud's disease very closely, and in older patients arterio-sclerosis may give rise to similar colour changes in the fingers and toes. These diseases are steadily progressive, leading to gangrene of the greater part, or even of the whole of several digits, and it is most important that they should not be confused with Raynaud's disease in which such extensive gangrene is never seen.

Of those afflicted by Raynaud's disease over 90 per cent. are women, and this sex-incidence must be borne in mind if errors in diagnosis are to be avoided. Almost all the men whose symptoms resemble those of Raynaud's disease are actually suffering from some form of obliterative arteritis.

TWO GROUPS OF CASES

The questions which the sufferer from Raynaud's disease will ask are whether she is to expect the disease to become steadily worse or to tend towards spontaneous recovery; whether ulceration will extend deeply and lead to gangrene of the fingers; whether all the digits are likely to become ulcerated to an equal extent; and whether the benefit to be expected as a result of sympathetic ganglionectomy will justify the operation.

It is commonly stated in text books that the mildest form of the disease will run its course in a few years, leaving the patient subsequently free from abnormal sensitivity to cold. This view is almost certainly fallacious, the tendency being for the symptoms to become more pronounced as age advances; but in a large percentage of cases the malady is not progressive. The most important factor in prognosis is the rate of progress of the disease in the first 2 or 3 years. If by the end of that period there are no trophic changes in the fingers it is most unlikely that these will appear later. It is thus possible to divide all patients suffering from Raynaud's disease into two groups: those who develop ulceration of the finger tips and scleroderma after 2 or 3 winters and for whom the outlook is bad, and those who show little or no tendency to trophic disturbances and who with reasonable care should be able to escape these complications indefinitely.

The improvement which occurs when a patient is living for a time in a warm climate may cause her to think that the disease has undergone spontaneous cure, but disappointment on returning to colder surroundings is inevitable. If, however, a patient is able to make her home permanently in a warm climate she may do so with the assurance that she will derive more benefit from the move than from any other form of treatment, and if the temperature is uniform she is likely to remain free from attacks. Even in this country the choice of occupation may have a considerable influence upon the attacks, though the advantage of working for part of the day in warm surroundings is not to be compared with the benefit of living in a warm climate. It may be helpful, however, if the patient can work in a kitchen or in a restaurant rather than in a warehouse or in the open air, and it is to be noted that typewriting seems to be a particularly unsuitable occupation for those who suffer from Raynaud's disease.

THE TYPE OF LESION

The ulcers which occur in uncomplicated Raynaud's disease remain shallow, healing in warm weather and recurring when a cold spell produces another "attack." Since ulceration and scleroderma are associated with permanent structural changes in the coats of the small arteries these complications will become more severe should any other form of arterio-sclerosis supervene. Massive gangrene is unknown, and should it be necessary to amputate a digit on account of painful ulceration, sound healing of the stump is to be expected. The disease very rarely ends fatally, but infection spreading from an ulcer is a possible cause of death.

Though all the digits become cyanosed in an attack it is remarkable that some suffer more severely than others. The thumb is usually the least affected, but the fingers vary considerably as regards the intensity of the cyanosis and the incidence of ulceration. Two or three fingers of each hand may remain free from complications for many years, and there is always a good chance that they may escape entirely. Should it be necessary, therefore, to amputate a badly ulcerated finger, the operation may be undertaken in the reasonable hope that complications of equal severity will not occur in the remaining fingers.

EFFECT OF SYMPATHETIC GANGLIONECTOMY

In predicting the effect of cervico-thoracic sympathetic ganglionectomy it may be taken as a general rule that the more severe the disease the less satisfactory will be the result of the operation. The severity of the disease varies directly with the degree of susceptibility to the action of cold, and this is not abolished by sympathectomy, the beneficial effect of which depends on paralytic vasodilatation. In the most severe cases, which are complicated by extensive ulceration and scleroderma, structural changes occur in the small arteries, and full vasodilatation becomes impossible. Thus, though symptoms are relieved in almost all cases, the improvement is most marked when susceptibility to cold is of moderate severity and trophic complications are minimal. Operation will not be called for in the mildest cases because the disease is not progressive; it will be contra-indicated in the most severe form of the disease because the degree of vasodilatation obtainable will prove an inadequate safeguard against future attacks; but it will produce most gratifying results when the disease, though progressive, is of only moderate severity. Lumbar ganglionectomy can be relied upon to relieve the symptoms in the feet in all cases, the success of the operation being not only more *certain* but also more complete than that of cervico-thoracic ganglionectomy.

Though the hands may still become blue and cold after sympathectomy, the patient will no longer be debarred from working at various household and other occupations which necessitate exposure to cold, since prolonged exposure to more intense cold will be required to produce the attacks after operation. Besides the regaining of the use of the hands, one of the greatest benefits enjoyed as a result of operation will be the abolition of the pain previously experienced during the attacks of cyanosis and the period of recovery following them.

Operations for sympathetic ganglionectomy are practically free from risk to life, but there are certain drawbacks of which patients must be warned beforehand. For two or three months after cervico-thoracic ganglionectomy there is often troublesome aching pain in the shoulders and arms, and insomnia may be a disturbing feature, but both these complications, which seem to be due to a temporary upset of the circulation in the arms and in the brain, clear up spontaneously, though they may be severe enough to delay the patient's return to work for some weeks. The ocular manifestations of bilateral cervical sympathetic palsy are neither a handicap nor a disfigurement. After bilateral [illegible] male patients, though still pote[illegible] sterile. The effect on the colon is to cause a moderate increase in its activity, which is usually rather an advantage, and incontinence of urine or fæces never occurs. These post-operative complications will not contra-indicate operation if the patient is suffering much pain and disability, but might cause one to hesitate before advising operation in the milder cases of Raynaud's disease.

J. Paterson Ross, M.S., F.R.C.S.,
Assistant Surgeon, and Assistant Director Surgical Unit,
St. Bartholomew's Hospital.

SPECIAL ARTICLES

MARIE CURIE

The death occurred on Wednesday, July 4th, of Marie Curie, the joint discoverer of radium. The event occurred at the *sanatorium* of Sallanches (Haute-Savoie); she was 66 years of age.

Marie Curie was one of the group of discoverers which has, during the twentieth century, thrown new light on the fundamentals of physics. She may be said to have been inducted as a baby into the career which she was predestined to follow. The daughter of Prof. Sklodowska, of Warsaw, she was as a child familiar with laboratory work, and soon became her father's assistant. Possible involvement in political troubles under the Tsarist régime led her to leave Warsaw for Paris, where she obtained a post in the research laboratories at the Sorbonne. She rapidly became licencié ès Sciences Physiques et Mathématiques, and duly proceeded to the doctorate. In 1895 she married Prof. Piérre Curie, who had already publicly recognised the pre-eminent qualities of her scientific work, and they laboured together on the researches which culminated in the momentous discovery of 1898. The story of this discovery has often been told, but the principal epochs in it are as follows.

Henri Becquerel, in 1896, discovered that the crystalline double sulphate of uranium and potassium emitted a type of radiation which could penetrate a plate of silver opaque to light. He followed up this discovery by showing that the crystalline state had nothing to do with the phenomenon, and, further, that it was exhibited by the metal uranium itself. He suggested, to indicate the new natural manifestation, the felicitous term "radio-active," which is still retained for the large class of bodies which have been discovered in the intervening years. The outstanding work of Madame Curie, during an active collaboration with Prof. Piérre Curie, was the separation and identification of two new elements, one comparatively short-lived, named polonium after her native country, the other radium, which by the special circumstance of the length of its "average life," stands out conspicuously among the whole range of radio-active substances. Now, a substance like uranium is very feebly radio-active; on the whole, its atoms are breaking up exceedingly slowly—a gramme of the element would only decay to half this value in five thousand million years. Hence uranium is found in quantity; on the other hand, radon, the gas from radium, is transformed to half its value in just under four days, so that no really large quantity is available. From a gramme of radium the maximum volume of radon is just over half a cubic millimetre. Radium stands not only genetically between these two substances, but while being much more radio-active than uranium it is much less so than radon. Hence, ponderable quantities are available. The extraction of radium by Madame Curie from the pitchblende residues put at her disposal from the State manufactory of uranium in Bohemia, was a piece of work calling for the greatest skill, inventiveness, and patience. Within a few years of this discovery radio-activity became one of the most important phenomenon of physics.

Two outstanding matters in this connexion should be mentioned: first, the discovery by Lord Rutherford that thorium (the radio-activity of which was identified independently by Madame Curie and G. C. Schmidt) spontaneously gave off a radio-active gas; and, secondly, the vital interest to medicine of the application of X rays and radium. Those bold spirits, who had taken their courage in their hands and applied X rays to the body in therapeutic fashion, were not slow to do the same with radium once the similarity in the types of radiation was known. In 1910 the first International Congress of Radiology was held in Brussels, when the proceedings were attended by 500 delegates drawn from all quarters of the globe, Madame Curie, Rutherford, and Soddy being among the adherents to the new science. The congress asked Madame Curie to prepare a sample of pure metallic radium and to take the initial steps towards realising a standard of radium quantity. This was done in a remarkably short time, and physical laboratories were for the first time in a position to make accurate measurements of quantities of radio-active bodies on an agreed basis. Further, the congress, planning to institute a practical unit of radium emanation (radon), desired to honour the name of Curie by associating it with the unit. A curie was designated as the quantity of radium emanation in equilibrium with one gramme of radium element. As so often happens with the practical units of the physicists, paradoxical though it may seem, a submultiplier of the unit—e.g., milli-curie—is more often used than the unit itself.

For the ten years of their married life she and her husband worked hand in hand, the association being terminated by the tragic death in 1906 of Prof. Curie in a street accident; but already she had, in association with him and Becquerel, been in receipt of the Nobel prize. She continued to work, at first alone, and later with various assistants and a daughter, and published researches in many scientific periodicals on the phenomena of radio-activity. In 1911 she received again the Nobel prize for her chemical researches, while the Royal Society conferred on her the Davy gold medal. Learned academies followed suit, and few can have enjoyed so many of these honorary distinctions as Marie Curie, but no parallel receipt of wealth rewarded her efforts although the French Government provided her with a laboratory in the Rue Piérre Curie; but in 1929 a present of £10,000 was received from women admirers in the U.S.A., enabling her to devote herself without anxiety to the labours which absorbed her. Madame Curie, during her later scientific years, saw a new era initiated by the work of her daughter, acting in collaboration with M. Jolliot, her husband. They discovered, contrary to the opinion held for over 30 years, that some substances could be made radio-active. It is true that the effect is a very small one and lasts for a comparatively short time, things which in no way detract from the importance of the discovery, while history would seem to show that the beginnings of great things are often of very modest dimensions. It was a happy finale for Marie Curie to see her work being continued so brilliantly in the family circle.

Madame Curie was a great scientific figure and her name will live as one who enriched the fields of science and added a weapon to those previously wielded by medicine in its fight for health.

INTERNATIONAL HEALTH AGREEMENTS

THE WORK OF THE OFFICE INTERNATIONAL D'HYGIÈNE PUBLIQUE (PERMANENT COMMITTEE)

SEVERAL matters of interest are dealt with in a résumé just issued from the Office International d'Hygiène publique in Paris on the proceedings at the April–May session of the permanent committee of that body, which was attended by the delegates of 39 Governments under the presidency of Sir George Buchanan. The work, as in previous sessions, concerned in part the settlement or application of international agreements between governments on health questions and in part a comparison of data on topical questions of epidemiology and hygiene.

INTERNATIONAL AGREEMENTS

In the first of these categories came the question of standard quantities to be recommended in the case of ships being deratised by sulphur for the purpose of the International Sanitary Convention of 1926.

Deratisation.—The committee agreed to a report to be presented to health departments concerned dealing separately with fumigation by burning sulphur, by burning mixtures of sulphur and charcoal, by sulphur dioxide in cylinders, and by the use of the Clayton apparatus. Special attention was given to the allegation that jute sacks or gunny bags loaded in Calcutta had been responsible for the importation of plague into various places on the coast of South America. Suspicions of this method of transmission were supported by circumstantial evidence, but the Committee was unable to regard the thesis as fully proven, and recommended its further consideration when additional data are obtained by the Pan-American Sanitary Conference which will be held at Buenos Aires in November.

An opinion was expressed adverse to giving certificates that ships have been effectively deratised when the holds of the ship have not been emptied before the deratisation process. Some agreements between individual countries for facilitating quarantine operations were noted and facilitated. Among these is a system by which in northern European ports from Brest to the mouth of the Elbe, including British ports, the port sanitary authorities follow a system of direct communication one with another in regard to infectious diseases on ships. A more important agreement, particularly from the shipowners' point of view, is that by which a considerable number of countries are now concluding an accord to dispense either with the production of a bill of health or, at least, with the requirements that bills of health should bear visas obtained from their consuls in foreign ports.

Air Traffic. Yellow Fever.—In connexion with the extension of international health regulations to air traffic which has been effected by the Hague International Sanitary Convention for Aerial Navigation, 1933, the committee gave its attention to evidence that on some air routes mosquitoes are habitually carried from country to country by aircraft, and decided on a study of the most effective methods of clearing aircraft from these insects. Note was also taken of the progress made in the application of the mouse protection test in regions of Africa to determine whether particular regions show evidence of the existence within recent years of the virus of yellow fever infection. A study was undertaken of the significance in this respect of what are termed "silent areas"—i.e., those in which a material proportion of positive results to the mouse protection test are obtained but in which there has never been evidence of the actual presence of yellow fever. An investigation of the several questions arising out of these findings is being pursued.

Venereal Diseases. Opium.—The International Agreement of Brussels, 1924, which provides for the treatment of merchant seamen suffering from venereal diseases, received further attention, and a modified form of the international card given to the seaman has been proposed to the signatory Governments. Finally, the Committee reverted to a previous decision that for the purpose of the Opium Convention of 1925 an exemption should be made for ampoules of sterilised solutions of morphine and atropine containing as maxima 2 per cent. of morphine salt and 0·05 per cent. of atropine salt. It appeared that there was some risk of the use of these preparations as drugs of addiction, even when put up in this way. A further investigation was decided upon.

TOPICAL QUESTIONS OF EPIDEMIOLOGY AND HYGIENE

The second branch of the work of the session needs less notice since the different contributions on epidemiological and public health subjects will in due course be published in the monthly *Bulletin* of the Office International d'Hygiène publique. Notable among these contributions are reports from the Yellow Fever Commission of the Office based on work in Africa and America, associated with that of the Rockefeller Foundation, on the distribution and transmission of yellow fever, including a discussion of the "silent areas" above mentioned. Recent work on vaccination against yellow fever by attenuated viruses and by the serum of immunised horses was reviewed.

Cholera.—The question of the degree of danger presented by the healthy carrier of cholera vibrios, or vibrios allied to them, constantly arises in quarantine practice, and comes repeatedly before the Committee. A new stage was reached at the present session. It was announced to be the intention of the Indian health service, with the aid of the Indian Research Fund Association, to follow the recommendations pressed at previous sessions, and that a carefully planned scheme of work on typical and atypical vibrios will now be undertaken in suitable areas in India under conditions which permit the bacteriological results and the appearance of clinical cholera to be studied in association. Special attention will in this connexion be given to typing by sugar fermentation and also to the use of serums prepared from a heated antigen, as proposed by Bruce White. The Committee had been asked to specify the dosage of cholera vibrios necessary where protection has to be given by a single inoculation. With certain cautions and reservations, it adopted the figure of 8000 millions as an average dose for this purpose. A proposal to give official recognition to cholera prophylaxis by the administration of vaccine per os was rejected.

Small-pox and Vaccination.—An omnibus report presented by the subcommittee on small-pox and vaccination on modern methods of vaccinating and the effects of vaccination was accepted and will shortly be published. Further contributions were received on neurovaccine, and on dried vaccine, as well as on vaccine virus grown on the allantoic membrane of the hen's egg in incubation. The latter included a report by Goodpasture and others, presented by the delegate for the United States, covering some 1000 vaccinations done with this virus in schools in Tennessee, which yielded normal results and an insertion success of 94 per cent. The Committee considered that it remains desirable to destroy lymph from calves which, on post-mortem examination after the collection of lymph, are found to have tuberculous lesions.

Virus Diseases.—Some new epidemiological data regarding the increase of typhus in several countries were supplied; note was taken of the general interest which attaches to the work of Wilson Smith, Andrewes, and Laidlaw on the nature of the influenza virus, and arrangements were made for further international studies of the incidence of Weil's disease and leishmaniasis in Europe and along the basin of the Mediterranean. The present distribution of psittacosis shows that the particular preventive measures taken in the several countries affected need to be adjusted to very different circumstances, and that, while there has been a definite gain to European countries by their having acted together in 1931 to prohibit all importation of parrots at their ports, this joint action no longer has the importance which it then possessed.

On more general questions of hygiene it may be noted that a report is to be presented on the practice and results of "terminal disinfection" in different countries.

ROYAL SANITARY INSTITUTE

THE annual health congress of this institute was held at Bristol on July 9th–14th. The inaugural address was delivered by Mr. S. H. BADOCK, pro-chancellor and treasurer of the University of Bristol, who sketched the history of preventive medicine and outlined the present position of the fight against disease. He pointed out that the general attitude to the physician was still too often that of the woman who showed her bathroom to her visitors remarking: "Thank God, we have never had to use it yet." He criticised the long intervals between school medical examinations, the lack of correlation between school medical services and adolescent health care, and the prevalence of tuberculous milk.

The Presidential address to the section of preventive medicine was delivered by Prof. W. W. JAMESON, who recounted his experience in a tour through India and Malaya. The first problem that attracted attention, he said, was due to the magnitude of the population: more than 350 millions of people lived in India and only 17 per cent. of the men and 2 per cent. of the women were literate. There was a fairly comprehensive system of curative medicine, and research work of the highest class was in progress, but there was a lack of advance in sanitation and preventive medicine. Until the people had reached a higher educational and economic level some powerful force from the Central Government was necessary. The religious and political problems added enormously to the difficulties of public health workers, but Malaya was far less troubled by such problems, and the experience of rubber growers that antimalarial work was good business had greatly helped the sanitation of the country.

NUTRITION

Dr. H. E. MAGEE spoke on nutrition and the public health, emphasising the close association between these two subjects and deprecating the lack of coöperation between physiology and public health. There had been much research work on animals but not enough on mankind. A criterion of normality was urgently needed and a test for the early departures from normal. The many and discordant methods employed in the artificial feeding of infants showed that the correct method had yet to be discovered, and there was still a conflict as to the ætiology of dental caries. Ignorance and prejudice—as well as poverty—played a large part in malnutrition. Public health was more than a science, it was partly an art, and nowhere would the health officer be called upon to exercise his art more skilfully than in educating his people to correct dietetics and in breaking down prejudice and fads.

Prof. R. H. A. PLIMMER, speaking on the same subject, discussed the total quantity necessary for nutrition and the special importance of salts and vitamins.

The presidential address to the section of hygiene of food, which met in conjunction with the food group of the Society of Chemical Industry, was delivered by Mr. L. H. LAMPITT, D.Sc., Chairman of the Group. His remarks concerned the manufacture of ice-cream, and he declared that there was no reason why this increasingly popular material should not be kept absolutely sanitary.

Mr. J. MATTHEWS, of the Aluminium Plant and Vessel Co., also read a paper on ice-cream, showing the developments which have taken place and are still taking place in the equipment for preparing and distributing this commodity. The manufacturer has to provide plants for cleaning and sterilising and finds stainless steel almost ideal; the engineer, however, finds it rather difficult to handle. The ingredients have to be pasteurised, mixed, homogenised, and finally cooled. Mr. Matthews described the various pieces of apparatus which had been found most satisfactory for the divers processes. The adoption of package ice-cream was, he considered, a great step forward and all phases of production were being speeded up. The temperatures used were being carried to still lower levels and modern processing equipment gave ease and certainty of bacteriological control.

Mr. J. R. BARKER, M.R.C.V.S., discussed the legislation concerning milk, and claimed that the milk from tuberculin-tested herds was safer than pasteurised milk from the point of view of tuberculosis risk. He also pointed out that there were pecuniary advantages in establishing tuberculin-tested herds, even under the present milk marketing scheme.

He urged clearance of slum cowsheds and the encouragement of the rearing of cattle free from tuberculosis and provided with a resistance to it. Breeders and rearers of beef cattle knew how to do this and the knowledge was available to the dairy herdsman.

MATERNITY, CHILD WELFARE, AND SCHOOL HYGIENE

Dame Janet Campbell read the presidential address to this section, reviewing the history and present position of the services. She concluded that substantial progress had been made and that permanent services had been established which would compare very favourably with anything done in other countries. The machinery set up had contributed materially to an additional improvement in the physique of children and had unquestionably saved many women and children from serious damage to health and nutrition. At the same time it was important to appreciate the incompleteness of these services and the impossibility of expanding them without the coöperation of local authorities.

Dr. J. Greenwood Wilson asked the question: "Does breast feeding matter?" and answered that modern medical literature showed a divided opinion on this subject. Probably the truth lay between two extremes. Breast feeding had great advantages which should be recognised by medical men and pointed out to their patients, but on the other hand they must recognise the restrictions it placed upon the mother and realise that the individual woman must be studied, just as the individual child must be studied when the feeding was artificial.

POSTURE

Miss M. Forrester-Brown spoke on posture and its relation to health, pointing out that a child's natural instinct kept it rolling on the ground, climbing, swinging, turning somersaults, and dropping to sleep after meals, but that school routine reversed all this. Yet we were surprised after nine years of this treatment to find young lads and girls lacking in initiative and enthusiasm for work. Many American colleges had started departments for dealing with this aspect of education, and industrial firms had prospective workers graded as to posture and body build so that they might be put to work suitable to their type. Artists and writers had paid much attention to bodily posture, and it seemed strange that the subject should have been much neglected by educationists and gymnasts. Far too many of them even now seemed to think that the aim should be strength in individual muscles instead of that exquisite balance among many muscle groups which gave poise both in movement and in repose. Miss Forrester-Brown then explained the right way of standing, sitting, and lying, and pointed out that the attitude induced by the ordinary lounge chair should never be used, for it over-stretched the spinal joints while crowding up the abdominal organs and interfering with the full expansion of the lungs. The chief single factor in maintaining good posture was the tone of the abdominal muscles balancing the back muscles. The balance of the trunk was the same for practically all varieties of exercise; the spine was intended to be used as a spiral spring, but never to bend as a hinge. The best exercise to tone the abdominal muscles was the full, deep breathing of the Italian singers' type, learnt lying down. The importance of rest and of education in balance showed that manual labourers should take their recreation in light sports demanding coördination and skill, while the sedentary worker needed more vigorous exercise.

MENTAL HYGIENE

The problem of the mentally defective was discussed by Dr. H. Herd, who described it as a multi-factorial one. The defective had to be considered as an individual, as a member of the present community, and in relation to the community of the future. There was still inadequate ascertainment of defectives of school age, too much education of the ineducable, and a danger of high-grade cases being assessed above their merits and therefore not officially ascertained. Dr. Herd discussed the evidence before the Departmental Committee on sterilisation and approved its findings, while holding that voluntary sterilisation would leave the problem as large and as clamant as before. The defective, particularly the high grade, had possibilities which had not yet been fully exploited; socialisation could be made a practical policy. For the pathological low grade he put in a plea in favour of euthanasia.

Dr. Isabel G. H. Wilson pointed out the wide relationship between the Mental Treatment Act and maternity and child welfare. The pregnant woman might often benefit by treatment as a voluntary patient. Puerperal cases were suitable for temporary treatment. The Urgency Order, now extended to the rate-aided patient, enabled the authorities to remove from home a violent or frantic patient who was terrifying or even endangering her children. The mother, returning after treatment, might be unable or unfit to look after her home and family; here the provisions of the Act relating to after-care came to their aid.

Miss F. B. Udell described the value of the health visitor in health propaganda. In her opinion leaflets were extremely useful, but the widespread distribution of health literature without verbal instruction thereon was of little or no value. Much good work could be done by group instruction at clinics about sewing, housekeeping, cooking, economical and wise shopping, feeding and care of infants, infectious diseases, the value of prophylactic inoculation, dental caries, and defective vision. Every point must be followed up in the individual home. The teaching of the health visitor must be done in such a way that it stimulated the natural desire for knowledge inherent in all women.

MEDICINE AND THE LAW

Misreading of a Label

An unfortunate misreading of the label on a drug bottle was investigated at a Birmingham inquest last week. The jury returned a verdict of death by misadventure, attributing negligence to the sister in charge of the hospital ward concerned, but making it clear that the negligence did not amount to gross and culpable negligence. A 20-months-old child had been brought to the hospital suffering from throat obstruction. Its breathing had been so seriously affected that it was almost dead on arrival. An operation was performed to permit breathing from below the point of obstruction; an anæsthetic was not necessary. Artificial respiration succeeded and the child began to breathe again. The obstruction freed itself; the child vomited and a piece of bone was dislodged. Later the child became restless and the sister in charge of the ward sent for the resident surgical officer who ordered a dose of nepenthe. The sister poured out a dose from a bottle on which the dose was labelled as "Five minims to 40 minims."

402
[illegible] S. MEDICAL COLLEGE,
[illegible]ARY, JAIPUR.

She misread this, as she afterwards realised, as having stated "five minims in 40 minims." She thought the drug was diluted down to one in eight. The dose ordered by the surgeon had been five minims. The consequence of her mistake was that she gave a dose eight times too strong. There was evidence that the bottle was of an unusual type with which the sister would be unfamiliar. The foreman of the jury said that the jurymen were satisfied with the arrangements made at the hospital for dealing with drugs. It was evidently, as the coroner observed, one of those human errors which no training or precautions can entirely eradicate. The incident shows the importance of obtaining the utmost possible standardisation in labelling.

IRELAND

(FROM OUR OWN CORRESPONDENT)

UNIFICATION OF NATIONAL HEALTH INSURANCE

At the opening of the new offices of the Unified National Health Insurance Society on July 7th the chairman of the society, Mr. D. O'Donovan, stated that during the past six months 25 approved societies had been transferred to the Unified Society, including 10 of the largest which operated in the Irish Free State. The total membership transferred was about 310,000, to which were to be added 20,000 new entrants to insurance. About three-fourths of the insured population were now in the society. He hoped to have the remaining societies transferred during the next six months. The chairman went on to criticise the present system of flat-rate insurance, which, in his opinion, rendered their energies unproductive. He regarded it as essential that benefits should be related to the social and financial position of the individual insured person. He hoped that before long they would have a comprehensive scheme of insurance embracing all workers within its scope regardless of their rates of remuneration. Mr. Sean T. O'Kelly, Minister for Local Government and Public Health, in declaring the building open, said that he looked to the unification of national health insurance as laying the foundation of a new scheme of social insurance in general for the people of the country.

A HOSPITAL VENTURE

It was announced last week that the authorities of St. Vincent's Hospital, Dublin, have purchased a demesne of some 45 acres at Elm Park, Merrion, some 3 miles from the centre of Dublin. The property, formerly a seat of Lord ffrench, has recently been used as a golf-links. No statement has yet been made about the intentions of the hospital authorities in regard to their new purchase, but it is believed that St. Vincent's Hospital will eventually be transferred from St. Stephen's Green to the new site. The hospital, which celebrated its centenary a few months ago, is greatly cramped for space in its present site, and has no possibility of extending its borders.

CORRESPONDENCE

BACTERIOPHAGE IN CHOLERA

To the Editor of THE LANCET

SIR,—May I draw your attention to a slip in your very kind and valuable editorial on Bacteriophage in Cholera in THE LANCET of July 7th. Referring to cholera in the untreated and treated districts of Darrang and Nowgong the writer says :—

> "The figures show that in Darrang the death-rate, taking the average of three-year periods, fell steadily from 1924–26 to 1930–32 and in 1930–32 was lower than had ever previously been recorded, though remaining at a level considerably above that of Nowgong."

The three-year period cholera death-rates per 10,000 for these districts were :—

	Deaths per 10,000 per annum.	
	Darrang.	Nowgong.
1923–25	8·9	12·2
1924–26	11·6	14·6
1925–27	16·1	24·3
1926–28	11·7	15·7
1927–29	9·6	14·4
1928–30	4·5	4·3
1929–31	4·3	2·9
1930–32	6·0	0·7

The treatment of Nowgong with phage began in December, 1929. Perhaps you will kindly draw the writer's attention to these, for the comment as it stands might mislead those who have not access to the original paper.—I am, Sir, yours faithfully,

J. MORISON.

London, July 7th.

⁂ *Moving* averages were not referred to in our article, but actual averages for each three-year period. Thus the average annual death-rates of Darrang were 11·6 in 1924–26, 9·6 in 1927–29, and 6·0 in 1930–32, while the corresponding rates in Nowgong were 14·6, 14·4, and 0·7. The rate in Darrang in 1930–32 is lower than any recorded in the consecutive three-year periods back to 1906 and, roughly, only half the rate for 1924–26. These figures, we suggest, bear out the comment in our leading article.—ED. L.

THE DISTRICT ALMONER

To the Editor of THE LANCET

SIR,—I was glad to see both in *The Lancet* and in the *British Medical Journal* of June 30th a reference to the value of the hospital almoner, and a suggestion that there should be district almoners.

I have long held the view that some extension of the almoner service to others than those who happen to be attending a hospital was desirable. In the course of my work (though quite outside it) I am not infrequently written to or rung up and asked to put people in touch with organisations or institutions able to help. Sometimes I can do so, but generally my only course is to write to one of the lady almoners whom I happen to know and who invariably give me all the help or information that is necessary. When, as sometimes happens, the inquirers are in perfectly good financial circumstances, there seems no reason why they should not pay a fee for such information. They would, I feel sure, gladly do so and money so raised would go towards meeting any expense involved in placing at the disposal of all who might wish to take advantage of them, services that can do so much to smooth out difficulties that are common to all. At the moment these services are restricted to one class of the community.

I am, Sir, yours faithfully,

R. H. P. ORDE.

The British Hospitals Association, Grosvenor-crescent,
London, S.W., July 5th.

THE ST. JOHN CLINIC

To the Editor of THE LANCET

SIR,—To your note on the Order of St. John of Jerusalem in THE LANCET of June 30th, which showed the close association between the Order and the medical profession, might well be added the fact that the Order is now in control of this clinic, which formerly was called the London Clinic, and is now named St. John Clinic and Institute of Physical Medicine. While the Red Cross has its clinic in Regent's Park for the treatment of rheumatic and allied conditions, so the Order of St. John has one in Pimlico. The clinic is giving about 3000 treatments per week, and is serving a very real need in providing methods of treatment by the expensive apparatus used in physical medicine, which the patient is unable to obtain from his panel doctor.

During last year there was added to the clinic an X ray department and three new baths, including a paraffin wax bath which is of new design and affords great relief to patients; 112 treatments were given last week with this paraffin wax bath, and all the patients seem to bless its influence.

I am, Sir, yours faithfully,

LEONARD HILL,
Supervisor, St. John Clinic.

Ranelagh-road, London, S.W., July 6th.

A DISCLAIMER

To the Editor of THE LANCET

SIR,—My attention has to-day been drawn to an article in the *Empire News* which refers to me by name and prints my photograph. I was entirely ignorant of the whole matter till to-day, nor have I the slightest knowledge as to how the material for the article, or the photograph, were obtained.

I am, Sir, yours faithfully,

Harley-street, W., July 10th. HENRY YELLOWLEES.

PANEL AND CONTRACT PRACTICE

Clerical Work

THE Glamorgan insurance committee recently recommended that £10 should be withheld from a practitioner's remuneration because of failure to comply with regulations requiring him to send in records on request and failure to reply to communications addressed to him by the clerk. He had been interviewed by the committee on a previous occasion, when he had promised to post off the records required the same night. He did not do so. This type is quite common in the insurance world, and it does no good to the profession when these facts are published in the daily press. While there may be no reflection upon the doctor's capacity professionally they do reflect on his organising ability. The keeping of records and the answering of letters promptly are very largely questions of method and temperament. If a practitioner dislikes this kind of work—which incidentally is important to his whole practice apart from his insurance obligations—he will often find that the services of a secretary, even for a few hours a week, are sufficient to free him from much worry and anxiety. Furthermore, in getting this help he will be assisting his brother practitioners, for they require the record cards he fails to send. Lastly, there is no disputing the fact that a prompt and courteous correspondence with the clerk of the insurance committee—who, after all, is only carrying out the committee's instructions—puts him in much better favour with that tribunal's medical service subcommittee if and when they have to deal with some complaint against him. The small outlay required will amply repay itself in the end.

The Causes of Incapacity for Work

The Department of Health for Scotland has just issued its third report on illness in the insured population. It deals with the year ending on June 30th of last year.

In a population of 1,768,872, the total volume of incapacitating sickness was over 18 million days, being 10 per cent. more than for 1931–32. The increase is greater among men than women, and among women it relates only to the unmarried, since the married show an improvement of 5·8 per cent. It is partly attributable, no doubt, to influenza, but this cause in fact accounts for only 30 per cent. of the increase in days of work lost. The balance is almost entirely due to an increase in the average duration of illness, which was 9·44 days for males, 12·36 for females, 11·05 for single females, and 21·52 for married. Among the causes of incapacitating sickness respiratory disorders amount to some 45 per cent., and they account for 23 per cent. of the total days lost. As regards duration of incapacity, influenza generally takes 15 days; appendicitis 59; pregnancy 40; nervous debility 80; and neurasthenia 122. The following figures denote the number of cases per 100,000 insured persons.

—	M.	F.	Average duration in days.	
			M.	F.
Tuberculosis	128	153	432	473
Anæmia	20	1000	93	53
Infective diseases	269	565	34	38
Gastric and duodenal ulcer	258	92	87	97
Appendicitis	312	597	57	61
Neurasthenia	96	211	145	101

M.=males; F.=females.

It will be noticed that "anæmia" and "neurasthenia" is a less frequent form of incapacity in men than in women; but when the men do give up work for these reasons they take much longer to become fit again. The following figures show the difference in the rate of recovery by the three groups—males, married females, and single females—in various age-groups in the two commonest incapacitating illnesses —influenza and respiratory troubles. The figures give the average duration of incapacity in days.

—	Age			
	under 20.	20–25	25–30	50–55
	INFLUENZA			
Males	13	13	13	18
Married females.. ..	26	21	22	23
Single females	15	16	16	23
	RESPIRATORY DISEASES			
Males	16	15	15	17
Married females.. ..	24	23	28	33
Single females	17	16	19	24

The question arises why a married woman under 20 should take nearly twice as long to recover from influenza as a man or a single girl of the same age. In the respiratory group again the married woman takes much longer to recover and both sets of figures show how the married woman obtains more days' sick pay for her illnesses than the man or the unmarried girl.

The days of incapacity per person are 10·8 in the burghs and 9·6 in the counties, both being higher than last year. Taking individual burgh committee areas, in Dumfries and Maxwelltown it takes the average case 15 days to get well; this is the highest for the Scottish burghs. In Greenock, on the other hand, the average is 7·9 days, this being the lowest. The figure for Edinburgh is 8·4 days. The highest figure for the county committee insurance area is 12·4 days (West Lothian and Zetland). The lowest figure is 6·2 in Perth—exactly a half.

It is estimated that influenza cost the fund £220,000; rheumatism £235,000; and all respiratory diseases, including influenza £515,000. When the money is paid out the age-group which receives the most is that from 20–25—namely £295,000. But this group is larger than any other, containing about 16·3 per cent. of the males and 25·6 of the females. The group 25–30 comes next, receiving £230,000, and the sumsthen gradually fall away until we reach group 50–55, which receives £120,000. It then rises for age-group 55–60, which receives £135,000, up to group 60–65, which gets £225,000.

OBITUARY

SIR JAMES KINGSTON FOWLER, K.C.M.G., K.C.V.O., M.D.

CONSULTING PHYSICIAN TO THE MIDDLESEX AND BROMPTON HOSPITALS

WE regret to announce the death of Sir James Kingston Fowler, consulting physician to the Middlesex Hospital, which occurred on July 3rd at his country house at Beaulieu, Hampshire.

SIR JAMES KINGSTON FOWLER

[*Photograph by Elliott & Fry*

James Kingston Fowler was one of the large family of the late Mr. James Fowler of Woburn. He was born in 1852 and educated at King's College, London, proceeding to King's College Hospital for his medical training. He qualified as M.R.C.S. Eng. in 1874, and held a series of house appointments at his hospital, after which he became house physician to the Addenbrooke's Hospital, Cambridge, entering at the same time Gonville and Caius College as an undergraduate. The post of resident at Addenbrooke's at that time was one of two or three years' duration, and Fowler was admitted to the usual privileges and restrictions of an undergraduate at Caius while living in the hospital. Though rather older than the men of his year, he was a popular member of the college and made many close friends. He graduated in arts and medicine, proceeded to the M.D. degree in 1884, and had in the meantime become M.R.C.P. Lond. In 1886 he was elected F.R.C.P., having been appointed to the staff of Westminster Hospital as pathologist and curator of the museum. This appointment was held for a very short time when he became in the same year assistant physician to the Middlesex Hospital and to the Brompton Hospital for Diseases of the Chest. At both institutions he gained much and deserved credit for his work as clinician, teacher, and lecturer, and the well-known treatise on diseases of the lungs which appeared in 1898, written in collaboration with Rickman Godlee, was a proof of the use to which he had put his opportunities in both places. No doubt the excellent order with which the information in "Diseases of the Lungs" was marshalled, the clearness of arrangement, and the due proportion of space allotted to the different subjects, were assisted by the fact that shortly before its appearance Fowler had edited a "Dictionary of Practical Medicine" by various writers, which met with considerable success, being regularly republished for nearly 30 years. The work of Fowler and Godlee proved an important addition to the literature of scientific and practical medicine, and brought home to readers 40 years ago the lesson—a commonplace to us now—that subjects ought not to rest wholly within the province of either physician or surgeon for their complete exposition. Fowler was the main author, but Godlee collaborated throughout and in special sections; the work, from the moment of its publication, took its place as a standard authority on a subject of high importance.

Fowler's interest in medical education was every whit as influential as in clinical medicine. He was not only a sound and careful teacher, but an experienced examiner, having discharged examining duties in behalf of Cambridge University, the English Conjoint Board, and the War Office. He knew the standards needed in the varying circumstances, and he knew the qualities of varying groups of students. Now in 1900 the University of London was reconstituted with the intention of strengthening the ties between it and the metropolitan institutions engaged in higher education within a radius of 30 miles of the centre. Under the new plan institutions situated within the administrative county, and not carried on for the private profit of owners, could be admitted as schools of the University, with the result that the medical schools of the London teaching hospitals, while preserving their independence, were also recognised as an integral part of the University. The absence of proper facilities for graduation at their University by London medical students was at that time a subject of wide dissatisfaction, and more than one scheme, intended to remedy what was felt to be a hardship, had been put forward previous to the reconstitution of the University. Fowler had been a moving spirit in at any rate one such scheme. And so, with the arrival of the reconstitution of the University, he became prominent in promoting medical graduation among the London schools. As a member of the Senate he was not wholly a success; possibly he knew too much, for although he made his points he gained them slowly and sometimes with difficulty. He was better seen at meetings of a more homogeneous and less formal nature; here his was a valuable voice, and he was both wise and courteous in laying before the permanent staff questions of procedure when they became of a technical character, which was not unusual in the working of the complicated machinery of the University. The value of his services was expressed by his election as dean to the faculty of medicine, a significant compliment to the medical man chosen, for the vote is a testimony of a large electorate to ability and loyalty.

Arising out of his interest in medical education in this country and in the opportunities for the employment of British graduates overseas, Fowler was early brought into contact with the Colonial Office. He served on a departmental committee whose recommendations led to the establishment in 1909 of a Colonial Advisory Medical Committee with himself as one of its first members. The work of this committee, though in kind it was apparently far removed from his other professional activities, became one of the chief interests of Fowler's later life, and he continued to take an active part in it even after his removal from London to Beaulieu. His wise, shrewd, and kindly counsel was greatly valued in the Colonial Office, and his advice influenced in a large way the development of medical services throughout the Colonial Empire. He was indeed deeply concerned to ensure that the medical personnel of the Colonial Service should be adequate in quality for what he conceived to be its great task, and as chairman for many years of a Medical Appointments Board he laboured with this object in view, with results that are now known. His services in this and other capacities in the Colonial Office contributed greatly to the improvement of health conditions in the tropical colonies and towards the enhancement of the prestige of British medicine overseas.

Sir James Kingston Fowler continued to serve until his death as a trustee for the Beit Memorial Fellowships, but his main work was done during the long period of 21 years in which he was also honorary secretary. Both the inception and the successful development of the scheme were due in great part to his influence. During his earlier training as a physician he had worked in several medical schools, and he was therefore able to rise above that intense but narrow loyalty which often makes a man keen to serve his own school but less concerned for the university. When dean of the Medical Faculty of London University he supported strongly the plans for centralising the teaching of preclinical subjects in some large institutes, and for this purpose his medical acquaintanceship with the great South African financiers enabled him to obtain a gift from Mr. Alfred Beit. The proposed institute was never built, and the money was returned after Alfred Beit's death to his brother, Sir Otto Beit. Sir Otto took this nucleus of £50,000, added £165,000 in his own gift, and established in 1909 the Trust for the Beit Fellowships. Fowler, both as original trustee and as secretary of the Advisory Board, was in a central position for guiding the subsequent development of the Trust, and he used his knowledge of men and of practical affairs with a characteristically clear judgment which influenced most happily all that was done. When the Advisory Board met at his house for the selection of Fellows each year, Fowler would deliberately abstain from much comment on the merits of the candidates, for he had taken care that all other members of the Board were Fellows of the Royal Society and he deferred to their judgment in matters of scientific work. "But every now and then," we are told by one who had sat at the Board with him, "he would end a debate by stating some clear-cut principle of which his experience of life had taught him the value—it was an action not unlike the swoop of the hawk, the hunting bird that he admired." The decision to create a senior Fellowship in 1927 for work in tropical medicine reflected Fowler's own interest in that subject since the time when he had been chairman of the Yellow Fever Commission for West Africa. He watched the studies of the Fellow with the most eager sympathy and was deeply disappointed when this promising work had to be stopped owing to the danger of its continuance in London. Not many of his colleagues on the Beit foundation knew him personally, and it was impossible for him, trained as a clinician, to follow their investigations along the intricate ways of the modern sciences ancillary to medicine. Fowler viewed the work of the Trust rather as a whole, and he was proudly conscious that that work was good during all the 21 years in which its guidance lay in his hands.

In 1907 Fowler was president of the Medical Society of London, in 1910 was appointed K.C.V.O., and shortly afterwards he became consulting physician to the Middlesex Hospital and to the Brompton Hospital. On the outbreak of war he was appointed consulting physician to the British Expeditionary Force with the rank of Lieut.-Colonel, and was mentioned in despatches and received the C.M.G. at the termination of hostilities. He was promoted K.C.M.G. in 1932 on his retirement from the Medical Appointments Board of the Colonial Office and in recognition of services rendered as chairman of the Yellow Fever Commission of West Africa.

Apart from the publications already mentioned, Fowler contributed the articles on bronchiectasis and syphilis of the lung to Allbutt and Rolleston's "System of Medicine," wrote a treatise on pulmonary tuberculosis, which appeared in 1921, and in various quarters upon the problems in tuberculosis. After his retirement he issued an interesting history of Beaulieu Abbey, of which he was warden, a post that gave great satisfaction to his deep antiquarian tastes.

BRENNAN DYBALL, M.B. Lond., F.R.C.S. Eng.

SURGEON TO THE ROYAL DEVON AND EXETER HOSPITAL

THE death occurred on June 29th of Mr. Brennan Dyball, an outstanding figure in Exeter and neighbourhood as surgeon and ophthalmologist. He was born in 1872, and received his medical education at St. Thomas's Hospital, where he was Beaney scholar in surgery. He had an outstanding career as a student, for immediately after taking the English double diploma he graduated as M.B. Lond. with honours in medicine and obstetric medicine, while at the examination for the B.S. he obtained the University scholarship. At St. Thomas's Hospital he was house surgeon and assistant demonstrator of practical surgery in the school, and was for a time resident medical attendant to the Hospital for Sick Children in Great Ormond-street. He next became resident surgical officer to the General Infirmary in Leeds. Some 20 years ago he commenced his long association with Exeter by appointment as anæsthetist to the Royal Devon and Exeter Hospital, to which institution he became assistant surgeon in 1912, and later full surgeon. At the same time he was surgeon to the Sidmouth, Exmouth, and Winsford cottage hospital, and held other positions of professional responsibility.

Dyball achieved his fine position through the thoroughness of his work, and his sterling qualities of character. R. A. W. writes of his colleague and friend: "By the death of Brennan Dyball the medical world in Devon has lost a pillar of strength. To those who knew him intimately he was a most engaging personality. His intellectual gifts were exceptional, and being an omnivorous reader there seemed to be no subject upon which Dyball could not illuminate a discussion. He was by nature shy and retiring, and anything savouring of self-advertisement was abhorrent to him. He hated public speaking, and on this account could never be induced even to take the chair at a dinner. Nevertheless he did an immense amount of work on hospital committees, and his insight and judgment were such that most of his colleagues were only too ready to follow his lead. He was absolutely free from pose, had a complete intellectual honesty, and a kindly sense of humour. In all affairs his sincerity and disinterestedness were so obvious that he never seemed to make an enemy, though he was tenacious of purpose. Money appeared to mean little to Dyball. It was far easier to get him to operate than to induce him to collect his fee. He started with some years of general practice, and acquired a clinical judgment out of the ordinary. I have heard it said that he was as good a physician as a surgeon, and as an abdominal surgeon he was in the first rank—at his best, perhaps, in a tight corner. An unexpected condition in the abdomen, at a house far away in the country, lighting not too good and instrumentarium limited—then Dyball was brilliant. Since the war he had interested himself in bone and orthopædic surgery, where a flair for carpentry showed itself in the neatness and ingenuity of his work. He shares with Dame Georgiana Buller the credit for the planning and organising of the Princess Elizabeth Orthopædic Hospital in Exeter, which has inaugurated an extensive service for cripples in Devonshire. There is no doubt that Dyball shortened his life by overwork, notably by the thoroughness with which he carried out a mass of voluntary and unpaid labour. For several years he undertook a large proportion of the operative work at the orthopædic hospital which, in addition to that at the Royal Devon and Exeter Hospital and an extensive private practice, was really too much for one man who worked as conscientiously as Dyball. This tribute is from one who has worked with him for close on 25 years and owes much to his friendship."

Mr. Dyball died at his country cottage in Haytor. He had been operated on three weeks previously, had left the hospital, and appeared to be making a satisfactory recovery in his moorland retreat when the sad end occurred.

JOHN FREDERICK JENNINGS, M.B., B.S. Lond., F.R.C.S. Eng.

WE regret to announce the death, at his house in John-street, Mayfair, London, of Dr. John Frederick Jennings, one of the best known general practitioners in the district.

Born at Cardiff in 1875, the son of Mr. T. M. Jennings, J.P., a shipowner, Jennings was educated privately with the intention of entering his father's business. But deciding on a medical career he went for his medical training to St. Bartholomew's Hospital. Here he was a successful student, obtained the English double qualification in 1900, and took the degree of M.B. Lond. in 1901. Two years later he took, with honours, the degree of B.S., and at the same time he acquired the F.R.C.S. Eng. At St. Bartholomew's hospital he held a series of posts, being house surgeon, midwifery interne, and clinical assistant in the throat department, and for a time his intention to enter consulting ranks was suggested by his appointment as demonstrator of pathology in the hospital medical school. Here, as in his previous posts, he was quite successful, but he eventually turned to general practice and, apart from the war period, worked in Mayfair for 30 years, that is from 1904 onwards. During the war he was consulting physician to the Swedish War Hospital and also acted as surgeon specialist to the Queen Alexandra Military Hospital, Millbank.

A personal friend writes of him as follows:—"Jennings, known to a wide circle of friends as 'Fred,' was an extremely popular man as well as capable physician. He had the confidence of his numerous patients and deserved it, so alert was his intelligence; his reputation gained with his experience of 30 years, and while rarely at a loss over a case his own great equipment helped him to see when he needed other counsel. Then his range of personal friendship in the profession enabled him to get into touch with right opinions when further advice was needed. All those who knew him felt that he might have achieved high honour in specialist ranks, but they could see that in his preference for general practice he had found the right field for his talents. His deep, reassuring voice, his unfailing good humour, his gifts as a raconteur, and his obvious enjoyment of London life, were of value to him and his patients in the daily round—they helped to complete their trust and confidence. A regular visitor to Covent Garden and an enthusiastic golfer, usually at Walton Heath, he added in both places to a vast list of friends and acquaintances. He will be much missed in the sick-room, in the club house, and at the dinner-table; his big personality has left its mark."

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 30TH, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 1 (last week 2); scarlet fever, 2289; diphtheria, 1115; enteric fever, 20; acute pneumonia (primary or influenzal), 676; puerperal fever, 30; puerperal pyrexia, 79; cerebro-spinal fever, 31; acute poliomyelitis, 6; acute polio-encephalitis, 2; encephalitis lethargica, 15; dysentery, 6; ophthalmia neonatorum, 102. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on July 9th–10th was as follows: Small-pox, 1 under treatment, 0 under observation (last week 3 and 1 respectively); scarlet fever, 1593; diphtheria, 1594; measles, 1224 (last week 1331); whooping-cough, 293; puerperal fever, 26 mothers (plus 9 babies); encephalitis lethargica, 268; poliomyelitis, 2; "other diseases," 201. At St. Margaret's Hospital there were 11 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there were no deaths from small-pox, 2 (0) from enteric fever, 23 (7) from measles, 3 (1) from scarlet fever, 25 (5) from whooping-cough, 50 (8) from diphtheria, 47 (13) from diarrhœa and enteritis under two years, and 21 (1) from influenza. The figures in parentheses are those for London itself.

Of the deaths from measles 3 were in Stoke-on-Trent; Oldham and Bristol each reported 3 from whooping-cough. Diphtheria caused 6 deaths in Liverpool, 4 each in Manchester and Warrington, and 3 in Leeds. Of the deaths from diarrhœa and enteritis under 2 years, 6 were in Birmingham and 5 in Manchester.

The number of stillbirths notified during the week was 321 (corresponding to a rate of 47 per 1000 total births), including 41 in London.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Public Health Services

ON July 3rd the House of Commons went into Committee of Supply on the Civil Estimates, 1934. Captain BOURNE (Deputy Chairman of Committees) was in the chair.

The debate was resumed on a Vote of £13,639,924 for the salaries and expenses of the Ministry of Health.

Mr. RHYS DAVIES moved to reduce the vote by £100. He said that all over the country the medical profession were doing excellent work in the conquest of disease, but the Minister of Health did not make any reference to cancer, rheumatism, or nervous disorder. With reference to national health insurance it was perhaps known to hon. Members that within the scheme there was a regional medical staff, and also a Dental Benefit Council. He understood that the Ministry of Health was working on a scheme to provide that the insured population should also receive their rights in connexion with optical benefit. He would be glad if the Minister could say something about the new Optical Council which he believed was about to be formed to see that optical benefit was properly administered. He also asked the policy of the Ministry in relation to the provision of more maternity homes. There had been a regrettable reduction of £500 in the provision for the training of midwives and health visitors, which was £26,500 in 1934. He asked whether a successor was to be appointed to Dame Janet Campbell, who had done excellent service for the health of the community, and if so when the new appointment would be made, and whether the circular to local authorities pointing out the directions in which the development of their services were still required, particularly in areas where the rate of maternal mortality was highest, had yet been issued?

Mr. PICKERING said that even if the slum clearance problem was proceeded with at the rate anticipated by the Minister of Health, and some 200,000 slum dwellings were cleared away and replaced by a corresponding number of good houses in the next five years, nevertheless the actual housing problem would not have been advanced any further because there would still remain an enormous shortage of "C" class dwellings which the poorest paid workers could rent at figures which they could afford to pay.

Mr. WEST said he shared the optimism of the Minister in regard to the great improvement in the health of the country, but there were still many black spots to be found in England, and he referred particularly to such places as North Kensington, where the infantile death-rate was nearly three times as high as that in South Kensington.

Sir FRANCIS FREMANTLE said that those who were concerned in the study of cancer were generally of the opinion, though they were not unanimous—that would not become the medical profession—that there was no real increase, age for age, and like for like, in the incidence of cancer at the present time. It was quite clear that there was a change going on in the age-distribution of the population. A greater proportion of old people in the population meant that diseases of old age became more prominent per 1000 of the population. Cancer being a disease of those between 40 and 70, it had a larger prey, and the figures were increasing; but as far as they could make out from the figures in any one area under like circumstances the total affected between 40 and 70 was fairly stationary. But the outlook was hopeful, mainly because of the encouragement being given to research.

The same thing applied to a certain extent to the increase of rheumatism. The incidence of nervous disease and mental deficiency had in the past been marked by the fact that such disorders were regarded as having a stigma attached, and had been concealed. But when they got down to the problem and found that there was some reasonable prospect of treatment for nervous disorders, they were able by ascertainment to increase the apparent incidence of these disorders.

One of the most important subjects was infant mortality. There had been a constant decrease in the figures of mortality, from 153 per thousand 73 years ago to 62 per thousand last year. Comparing the infant mortality at the beginning of the century with that to-day, the Minister had saved something like 40,000 lives in the year. This drop in infant mortality applied not only to infancy but continued through the second, third, fourth, and fifth years of childhood. It was the present principal medical officer of the Ministry of Health who first drew the attention of medical officers generally to the fact that there was this blank in the public health. Whereas 35 per 1000 died in their second year before the war, the figure had now been reduced to 14; in the third year it had fallen from 14 to 6 per 1000; in the fourth year from 9 to 4 per 1000; and in the fifth year from 6 to 3 per 1000. It was remarkable how much the ordinary mother was learning to-day, and that result had been achieved largely through the activity of health visitors.

Maternal mortality was a pressing and difficult problem. In 1912 there were 3492 maternal deaths, which in 1932 had been reduced to 2587, but the rate per 1000 births had not gone down. It was under 4 before the war, and it was now nearly 4½. Those in touch with the work of midwives and district nurses in rural areas could not fail to be struck with the contrast between the general rate and the rate among those cases which were conducted by the midwives. In the last two centuries in this country we had rather departed from the system which still existed in many other countries, under which confinements were primarily the work of the midwife and not of the doctor. He hoped they were coming back to the system in this country, and that they would be able to get a body of properly trained midwives to conduct midwifery work, leaving the medical profession to be brought in for consultative purposes, or in the case of need, for the support and instruction of the midwife. But if that was to be the case the midwives would require to be trained for the purpose. More attention would have to be paid both to their original training and to their post-graduate training than was the case at present. Whereas the rate for the whole country was 4½ per 1000 births, in the cases dealt with by the Queen's Institute of District Nursing for the same year the rate was 2·1. There were several reasons for the difference. One was that mothers who were having their first confinement did not take risks and very often went into hospital, while complicated cases were not treated by the midwives. These cases got into the hands of the doctors sooner or later and therefore the figures did not afford a fair comparison as to the efficiency of one method or the other. But the fact remained that there was this comparatively low rate among the cases dealt with by the district midwives as compared with the figures for the whole country. There was, however, a slight increase also in their figures. One of the difficulties among mothers to-day was a question of diet; another was the shape of the pelvis. According to the departmental report on maternal mortality the shape was more adapted to easy childbirth in Dutch than in British women. He believed that training and exercises in early life might lead to improvement in that direction. Many cases—over one-third, he thought—were traced to puerperal infection, which often arose through the use of instruments in a hurry, and the desire to hasten the natural process.

Sir FRANCIS further asked whether the Mental Treatment Act, 1930, had not had the effect which was hoped for in encouraging patients to submit themselves voluntarily for treatment at a mental hospital. He was inclined to think there was too much officialdom. They could get voluntary treatment in incipient mental disease only by making it as easy and unofficial as possible. He also asked whether the Registration of Nursing Homes Act, 1927, had improved the working of those homes, and had led to the closing of unsatisfactory homes? Had it stopped undue profiteering and prevented fraud?

They saw the figures for tuberculosis with heavy minds after all the money that had been spent. In 1932 tuberculosis patients who died or were discharged from approved residential institutions numbered 39,000. Of these 500 died in institutions, nearly 9000 were discharged quiescent, and 24,000 were discharged not quiescent. The 24,000 discharged not quiescent went back to their homes, which were very likely overcrowded and in the slums, and they were spreading the disease among other people. After two, three, or five years they died, and all the work which had been put into sanatorium and dispensary work was wasted. Places such as Preston Hall in Kent or Papworth in Cambridgeshire gave much hope and encouragement, but were limited to a very small number. Could not some of the money which was to be devoted to slum clearance and rehousing be used for rehousing in village settlements like Papworth? He could not help thinking that by some coöperation between the Unemployment Board and the Ministry of Health there might be some hope of giving employment in training centres to unemployed people who were tuberculous.

Mr. SHAKESPEARE (Parliamentary Secretary to the Ministry of Health), replying to the debate, said that in regard to the drought and the urban water-supply the Ministry on the whole were looking forward with confidence to the future, always provided that the consumers could be relied upon to coöperate in reasonable economies. The Rural Water Supplies Act was helping to solve the permanent problem in the rural areas. In the two and a half months since the Act was passed they had had applications from 593 parishes in respect of capital works totalling £1,700,000. They had approved for grant water schemes in respect of 211 parishes amounting to a total capital of £700,000. That was twice the total of the last two years, and it was approaching the maximum figure ever reached under the predecessors of the present Minister of Health. He claimed that at that rate the permanent problem of water-supplies in rural areas would be very greatly alleviated. In view of an alarming article in the press alleging that there was an outbreak of scarlet fever and diphtheria, and that these diseases were everywhere increasing, he had sent for the best expert in the country. He had pointed out that scarlet fever and diphtheria were not diseases that were connected with absence of water, but that on the contrary those diseases came in cycles of four years or five years and that more often than not they occurred in areas where the water-supply was satisfactory. To sum up the water situation, he could say that by legislation, by administrative action, inspection, and conference they had been able to render great assistance to local authorities in the matter of the drought. Very much of what Mr. West had said about overcrowding causing disease and infant mortality could not be denied, and for that reason the Government were bringing in a Bill which particularly would apply to those troublesome aspects of the problem. The Minister of Health in his slum clearance crusade was in the next five years putting at the disposal of local authorities for finding accommodation for the poorer paid workers 300,000 houses at a cheaper rent than anything which had been hitherto provided, and in connexion with the new overcrowding Bill that policy would be continued and the local authorities under subsidy where necessary would cater for the poorer paid workers. The machinery of slum clearance had started working and was gaining pace. At the end of the year he hoped they would be able to improve even on the present figures.

Wing-Commander JAMES said he regretted that in view of the unanimous report of the Departmental Committee on Sterilisation of Mental Defectives the Government had not found it possible to implement that report or to hold out any immediate prospect that they were going to do so. He would like to ask what steps were being taken to carry out the recommendations in respect of research that were made in Chapter 7 of the report.

Dr. O'DONOVAN said that surely it was selfishness to want to raise their own standard of living by mutilating the bodily integrity of those who were admittedly their weaker brothers. People classed as mental defectives belonged to a class which the medical profession found the utmost difficulty in labelling. In the medical press there were many articles pointing out that many so-called mental defectives were in fact dullards. Any breach of the affection and trust which existed between patient and doctor would be to the greatest disadvantage to the calling of medicine. Another difficulty would arise in public life and in hospitals if administrators insisted on sterilisation as being good for the State, while doctors and nurses for professional and conscientious reasons differed from such conclusions.

After further debate,

Sir HILTON YOUNG (Minister of Health) said that with the assistance of the approved societies and his advisers he had constantly sought for means of relieving the position in regard to arrears under National Health Insurance. They had taken measure after measure for that relief, and it had been very effective. In order to simplify the matter and to assist the position of those who were now falling into arrears they had now succeeded in arranging that the reduction of arrears of contributions from 1*s.* 6*d.* to 9*d.* should apply to all those who, owing to unemployment, were falling into arrears. That was a very big concession indeed, and one which they were told by the approved societies would make a very great alleviation of the situation for the unemployed. In regard to maternal mortality, it was the intention of the Ministry to press ahead with the development of the service for the sake of mother and child. They would not be content until these services in every part of the country were as good as they were in the best equipped towns. He proposed at the proper time to renew the measures for stimulating efforts of this sort by a direct message to local authorities. If the methods they were adopting did not succeed they must proceed to others.

The motion to reduce the vote was rejected by 173 votes to 39.

Scottish Poor-law

In the House of Commons on July 5th the Poor Law (Scotland) Bill as amended in Standing Committee was considered.

The measure was recommitted in order that several amendments might be discussed which could not be discussed on the Report stage.

Mr. BUCHANAN moved an amendment to Clause 11 (Outdoor relief to members of friendly societies, &c.) to ensure that in affording outdoor relief to any person a local authority should disregard the first 5*s.* of his sick pay from a trade union, as well as from a friendly society.

Mr. SKELTON (Under-Secretary for Scotland) accepted the amendment, which was agreed to.

Mr. N. MACLEAN moved the first of three amendments to ensure that the local authority in assessing or allocating relief should disregard maternity benefit, any weekly payment by way of compensation under the enactment relating to workmen's compensation, and any pension under the Blind Persons Act 1920, and any other income by virtue of the provisions of that Act or from any charity for the blind.

After some debate,

Mr. SKELTON said that this was a case where he could not give a concession. In Scotland all the local authorities except two had special schemes whereby assistance to destitute blind was not given by way of public assistance but under the Blind Persons Pensions Act. He proposed to take the matter up ith the two authorities to whom he had referred, nd ask them to come into line with the rest of otland. The Government were not prepared to move from local authorities the discretion to disgard half the amount of workmen's compensation n applicant received. With regard to maternity enefit his information was that it was generally isregarded.

At a later stage,

Mr. SKELTON announced that having been impressed with the debate he would accept the amendment in espect of maternity benefit, but on the distinct understanding that it should be redrafted when the Bill reached the House of Lords.

The amendment was agreed to.

Mr. MACLEAN then formally moved the amendment relating to payments by way of compensation, this being negatived by 183 votes to 48.

The amendment dealing with pensions under the Blind Persons Act 1920 or from any charity for the blind, also formally moved, was negatived by 190 votes to 34.

The Bill passed through the report stage and was read the third time by 143 votes to 29.

Road Traffic Bill

In the House of Lords on July 10th the Road Traffic Bill (which has passed through the House of Commons) was read a second time.

HOUSE OF COMMONS

WEDNESDAY, JULY 4TH

Safety Glass in Public Service Vehicles

Mr. HOLFORD KNIGHT asked the Minister of Transport whether, in the interests of public safety, he would make it compulsory for all public vehicles to be equipped throughout with safety glass.—Mr. HORE-BELISHA replied: Since Jan. 1st, 1932, the regulations have required, as regards new vehicles, that all glass fitted to windscreens or windows facing to the front on the outside of any motor vehicle, except glass fitted to the upper deck of a double-decked vehicle, shall be safety glass. As at present advised, I do not think it necessary to make the use of such glass throughout public service vehicles compulsory.

Replying to a further question by Mr. Knight, Mr. Hore-Belisha said that he would be ready to give further consideration to any suggestion.

Air Attack with Disease Germs

Sir NICHOLAS GRATTAN-DOYLE asked the Prime Minister whether he was aware that evidence existed that experiments were being made and secret German plans perfected by the Luft-gas-angriff department for the destruction of human beings in war by aircraft carrying deadly disease germs; that experiments had been made concerning the vulnerability of underground railways in London and Paris; whether he had considered the evidence; and what action, if any, he proposed to take.—Mr. BALDWIN replied: I have seen allegations to this effect in a published article. They have been officially denied by the German Government. The question of the vulnerability of the underground railways in London is kept under constant observation as part of the general question of air raids precautions, but I do not consider it in the public interest to make any further statement.

THURSDAY, JULY 5TH

Coroners' Jurisdiction and Disposal of Bodies

Mr. LAWSON asked the Home Secretary whether he was aware that considerable distress was caused to relatives of persons fatally injured just within the boundaries of one coroner's jurisdiction while their homes were in another; that the bodies sometimes lay for two or three days in the mortuary before being conveyed to the homes of relatives; and whether he could take steps to avoid the unnecessary pain arising from this practice.—Sir JOHN GILMOUR replied: Section 14 of the Coroners Amendment Act of 1926 empowers a coroner to issue a burial order at any time after he has viewed the body, and I have no doubt that coroners generally are ready to avail themselves of this power in proper cases.

Mr. LAWSON: In view of the very bad case that I brought to the right hon. gentleman's attention where a man's body was brought from the pit to Gateshead, just over the border, and then was taken away by a policeman, cannot the right hon. gentleman do something to modify the position in cases where there are two areas of jurisdiction?

Sir J. GILMOUR: I understand that in the case referred to the body was removed before the coroner had an opportunity of going into the matter. It is essential that the coroner should give an order.

Mr. LAWSON: Is the Home Secretary not aware that the bodies are removed immediately from the pit to their homes, but in this case it was simply a case of the coroner's fees, I understand?

Sir J. GILMOUR: I am very anxious, of course, to obviate any kind of unpleasantness in dealing with this problem, but it is essential from the point of view of the coroner that the removal of the body should not take place before he gives the order.

Captain HAROLD BALFOUR: In view of the unsatisfactory nature of this particular case, and the general unsatisfactory working in the case of fatal injuries and seriously injured persons on the roads, would my right hon. friend consider setting up a departmental committee in order to find out how far overlapping exists, and to try to straighten out the present unsatisfactory condition of things?

Sir J. GILMOUR: I am prepared to consider the whole matter. I cannot commit myself to what action I shall take.

State Medical Service

Mr. LLEWELLYN-JONES asked the Minister of Health whether he was aware of the movement both in the medical profession and also amongst friendly societies and national health insurance organisations in support of the setting up of a complete medical service for the whole of the population of the country; and whether he would favourably consider the appointment either of a parliamentary or of a departmental committee to explore the situation and to report as to the desirability of introducing legislation for the creation of such a service.—Sir HILTON YOUNG replied: Proposals on this subject have been brought to my notice and are being examined, but I am not at present in a position to indicate what action, if any, the Government may decide to take in relation to them.

Imports of Processed Milks

Sir PERCY HURD asked the Minister of Agriculture what arrangements had been made for the regulation of imports of processed milks after June 30th.—Mr. ELLIOT replied: The Governments of the foreign countries mainly concerned in the United Kingdom market for condensed milk, milk powder, and cream have been asked to arrange for the following reductions in supplies as from July 1st, the reductions in each case being based on imports during the corresponding months of the year previous to the introduction of the voluntary import regulation arrangements—namely, June, 1932–May, 1933:—

Condensed Skimmed Milk.—Continuance for the time being of the reduction of 22½ per cent.

Condensed Whole Milk and Milk Powder.—Continuance for the time being of the reduction of 20 per cent.

Cream.—Reduction of 33⅓ per cent. for the quarter ending Sept. 30th.

The Governments of the Commonwealth of Australia and of the Dominions of Canada and New Zealand have been asked to continue during the quarter ending Sept. 30th the coöperation which they have been good enough to afford since the regulation of imports of processed milks was first introduced. Arrangements are also being made to secure reductions in imports of condensed whole and skimmed milk and cream from the Irish Free State. It will be appreciated that, since the bulk of our imports of processed milks, other than cream, from foreign countries is supplied by the Netherlands, the position as regards import regulation is for the time being governed by the agreement recently concluded for the maintenance of the status quo in trade relations between the United

Kingdom and the Netherlands, pending the negotiations of a trade agreement.

Rehousing and Slum Clearance

Mr. Chorlton asked the Minister of Health if he was now able to announce the names of the members he had appointed to deal with the question of buildings involved in rehousing after slum clearance.—Mr. Shakespeare, Parliamentary Secretary to the Ministry of Health, replied: The members of the committee will be:—Mr. Ewart S. Andrews, B.Sc., M.Inst.C.E., M.I.Struct.E.; Mr. Henry V. Ashley, F.R.I.B.A.; Mr. Oscar Faber, O.B.E., D.Sc., M.Inst.C.E., M.I.Struct.E.; Mr. George Topham Forrest, F.R.I.B.A.; Mr. Ian B. M. Hamilton, B.A., A.R.I.B.A.; Sir George W. Humphreys, M.Inst.C.E.; Mr. B. L. Hurst, M.Inst.C.E., M.I.Mech.E.; Mr. L. H. Keay, O.B.E., F.R.I.B.A.; Mr. Francis Lorne, F.R.I.B.A.; Mr. J. A. Macintyre, O.B.E., B.Sc., M.Inst. C.E.; Mr. R. Travers Morgan, M.Eng., M.Inst.C.E., A.M.I.Mech.E., M.I.Struct.E.; Mr. Stanley C. Ramsey, F.R.I.B.A.; Mr. A. Scott, M.B.E., F.R.I.B.A., M.I.Struct.E.; Mr. W. L. Scott, M.Inst.C.E.; Mr. R. E. Stradling, M.C., D.Sc., Ph.D., M.Inst.C.E.; and Mr. J. Wilson, F.R.I.B.A., F.R.S.E. Sir George Humphreys will be chairman, and Mr. A. Zaiman, whose services have been lent by the Department of Scientific and Industrial Research, will be secretary of the committee.

Medical Practitioners and Motor Accidents

Mr. Temple Morris asked the Minister of Transport whether, in view of the proposed mulcting of a motorist of 12*s.* 6*d.* for the fee of a doctor when his car had been in collision with anyone, he could state whether the doctor in each case would be summoned by the parties to the accident or by the police, or whether it was intended that any individual should have the right to communicate with a medical man.—Captain A. Hudson, Lord of the Treasury, replied: The circumstances of accidents vary greatly, and a hard-and-fast rule as to who has the right to summon medical assistance would be likely to involve dangerous delays.

Medical Research

Sir Robert Gower asked the Secretary to the Treasury what sum had been devoted by the State this year to the promotion of medical research and what sum had been similarly applied during the last eight years.—Mr. Duff Cooper replied: The annual grant in aid of the Medical Research Council was £135,000 from 1925 to 1927 inclusive, £140,000 from 1928 to 1931 inclusive, and £139,000 in 1932 and 1933. Provision for a grant of £139,000 is included in the estimates for the current financial year. There are other contributions made by the State to medical research, but, apart from a grant of £100,000 in 1929 for the purchase of radium, it is not possible to give figures. Inclusive grants are paid to a number of universities out of which considerable sums are allocated by the University authorities to their medical schools, which include medical research among their activities, but it is not possible to distinguish the amounts applied to this purpose. In addition, medical researches are undertaken from time to time by the Ministry of Health and other Government departments.

Silicosis in South Wales

Dr. John Williams asked the Secretary for Mines the number of men certified for silicosis in the county of Carmarthen and in the rest of the South Wales coalfield; and the number of such cases where death had resulted from this disease.—Mr. Ernest Brown: I am informed by the Home Office that between June 1st, 1931, when the Medical Board under the compensation scheme was appointed, and May 31st, 1934, 105 miners were certified by the Board as disabled from silicosis in the county of Carmarthen and 279 in the remainder of the South Wales coalfield; and that the number of deaths certified by the Board were 26 and 57 respectively.

MEDICAL NEWS

Royal College of Surgeons of England

Election to the Council.—On July 5th four Fellows were elected into the council to fill the vacancies occasioned by the retirement in rotation of Mr. Ernest W. Hey Groves, Mr. G. Grey Turner, and Mr. Hugh Lett, and by the death of Mr. R. P. Rowlands. The result of the poll was as follows:—

	Votes.	Plumpers.
George Grey Turner (Newcastle) ..	903	6
Ernest William Hey Groves (Bristol)	841	3
Hugh Lett (London)	734	43
William Girling Ball (St. Bart.'s) ..	584	61
Ernest Cranmer Hughes	445	27
Alfred William Sheen	298	6
Duncan Campbell Lloyd Fitzwilliams	240	10
Gwynne Evan Owen Williams ..	210	13

In all 1995 Fellows voted, including 210 Fellows resident out of Great Britain and Ireland; in addition, 9 votes were found to be invalid, and 2 were received too late. Mr. Girling Ball becomes substitute member of council for the late Mr. Rowlands until 1938.

University of Oxford

The Theodore Williams Scholarship in Anatomy is to be divided between D. L. P. de Courcy and L. L. Whytehead; the Theodore Williams Scholarship in Pathology has been given to D. F. G. Moir. The master and fellows of University College have awarded the Radcliffe Scholarship in Pharmacology to H. M. Sinclair.

University of Leeds

On July 3rd the honorary degree of D.Sc. was conferred on Dr. Joseph S. Bolton, medical director of the West Riding Mental Hospital, and until recently professor of mental diseases at Leeds University, and Sir Robert Muir, F.R.S., professor of pathology in the University of Glasgow.

University of London

At a meeting of the court held on July 4th tenders from seven selected firms for the superstructure of the first of the buildings to be erected on the University's site in Bloomsbury were considered. The lowest tender received—namely, that of £362,579—was accepted. A condition of the contract will be the use throughout of materials obtained from sources within the British Empire. The contract will provide for the building of the senate house and administrative offices, a portion of the University library, and certain works connected with the hall.

The Kent county council has made a grant of £40,000, payable over ten years, towards the cost of the new University buildings.

University of Manchester

At recent examinations the following candidates were successful:—

M.D.

C. N. Aldred, Marguerite E. Cliffe, Benjamin Dunkerley, E. A. Gerrard (with commendation), E. R. W. Gilmore, J. M. Greenwood, E. F. Hill (gold medal), Geoffrey Lapage, W. H. Newton (with commendation), Gerald Ramage, and B. R. Sandiford.

CH.M.

W. B. McKelvie.

FINAL EXAMINATION FOR M.B. AND CH.B.

D. H. Mackay (second-class honours), Harry Baker, Monica D. Boyle, A. S. Bullough, W. P. Cargill, Neville Copeland, J. D. H. Cran, D. D. Cranna, Annie M. Dawson, I. H. Flack, Norman Goldstone, Harry Harris, Eileen M. Hughes, Fred Janus, N. F. Kirkman, Amy B. de V. Mather, G. H. Moore, E. L. Patterson, Ralph Spencer, and J. A. A. L. Woodhead.

Part I.—Monica D. Boyle, John Charnley, Eleanor B. Clarke, Mary A. C. Cowell, T. F. Davey, F. P. Ellis, William Fielding, F. I. Firth, Samuel Franks, Eric Greenhalgh, G. D. Harthan, E. H. Heilpern, K. H. Higson, A. D. Hoffmann, L. L. Husdan, J. I. A. Jamieson, W. E. Kershaw, A. F. Mackay, Ralph Mallinson, J. L. Morgan, Annie [illegible] R. L. Parish, C. S. Parker, J. N. Parker, G. R. [illegible] t Ross, Cyril Royle, H. L. Settle, J. N. [illegible] ute, Roland Thornley, H. J. Wade, J. R. [illegible] I. Williams.

iversity of Manchester

Dr. C. P. Lapage, lecturer in diseases of children, has n appointed to a university readership. Dr. J. F. slop and Dr. Eric Vernon have been appointed demonators in anatomy.

iversity of Edinburgh

On June 28th the degree of D.Sc. was conferred on . S. A. Kinnier Wilson.

iversity of Dublin

Dr. William Robert Fearon, Fellow of Trinity College, ublin, and hitherto lecturer in biochemistry in the iversity, has been appointed professor of biochemistry. . David Smyth Torrens, hitherto lecturer in histology, comes assistant professor of physiology.

niversity of Aberdeen

On July 9th the following degrees were conferred :—

M.D.

***T. N. Morgan, ***Ann L. Thomson, **Alexander Cruickank, **J. R. M. Mackie, *A. G. Badenoch, *Roderick Mackay, dward Farquharson, T. A. Fraser, W. H. Harris, A. W. enderson, Catherine I. A. Jamieson-Craig, and Mary Riddoch.

*** With highest honours; ** with honours; * with comiendation.

M.B., CH.B.

C. Ludwig (with second-class honours); E. P. Adel, . J. Beddie, Hugh Burnett, J. R. Byars, John Cameron, dward Cay, E. M. Darnley, I. K. Ettman, Jane R. Forgie, harles Glassman, J. F. R. Goodlad, J. T. Grassie, David Horn, . R. Horn, R. A. Horne, P. W. Ingram, M. H. Kirsner, A. H. asdon, L. A. Ledingham, A. P. Macdonald, J. C. McGregor, . A. M. MacLennan, J. H. S. Morgan, A. F. T. Ord, Gilbert arker, J. R. M. Sangster, I. M. Schnee, J. A. Shearer, Isadore hechner, S. R. N. Smith, E. J. Strachan, J. W. M. Sutherland, nd A. H. Weiner.

D.P.H.

A. G. Badenoch, Douglas Bell, Alexandra H. Duthie, and J. B. Ewen.

Jniversity of Birmingham

Dr. P. C. P. Cloake, honorary physician to the Queen's Hospital and to the Birmingham and Midland Hospital or Nervous Diseases, Birmingham, has been appointed professor of medicine in the university in succession to Prof. J. G. Emanuel.

Dr. Cloake qualified in 1915 afterwards serving in the Royal Army Medical Corps. In 1921 he graduated M.B. in the University of London and in 1923 obtained the university medal for his M.D. thesis. In 1924 he became a member of the Royal College of Physicians of London, and he has also obtained diplomas in public health and psychological medicine. Dr. Cloake served on the staff of the Ministry of National Service and Ministry of Pensions in Cambridge and in 1920 became deputy commissioner of medical services. During this time he acted as lecturer at Cambridge University and as honorary physician to the psychological department of Addenbrooke's Hospital. He returned to London on his appointment as registrar to the Hospital for Nervous Diseases at Maida Vale and became an assistant physician to the Metropolitan Hospital. In March, 1925, he went to Birmingham as assistant physician to the Queen's Hospital. He has held a research grant for work on organic nervous diseases in London [illegible] the author of one of the special reports of [illegible] Board. His other contributions to me[illegible] discussions of the mental sequelæ of [illegible] and the influence of the diencephalon on metabolism.

Applications are invited for the appointment of reader in industrial hygiene and medicine, and should reach the secretary of the University not later than Sept. 1st. The decision of the University to establish a new department for teaching and research in this subject was reported in our issue of April 28th (p. 927). Particulars of the appointment are given in our advertisement columns this week.

West London Medico-Chirurgical Society

On July 4th the president and Mrs. H. Tyrrell-Gray received the guests at the society's fifty-second annual dinner, held at the Trocadero Restaurant. As soon as everyone was seated, Sir Alfred Rice-Oxley rose to present a loving cup and chain purchased for the society with a legacy from Dr. Rickard Lloyd, a member of long standing who died early last year. The cup shows the names of 52 presidents, including Sir Alfred, and the chain embodies the badge of the society, presented by Charles Keetley. After dinner Lord Macmillan proposed the toast of president and society. Speaking of the value of professional gathering, he quoted the saying that "a rut differs from the grave in being a little narrower." Doctors were fortunate in their profession, for the term "beloved physician" had an almost canonical flavour; but who had ever heard of a "beloved solicitor"? After referring to his unmeasured admiration for the work done, especially in hospitals, by medical men, and particularly of Mr. Tyrrell-Gray's services at Great Ormond-street, Lord Macmillan concluded with an appeal for medical support for the University of London. In response, Mr. Tyrrell-Gray spoke very modestly of his own achievements and very warmly of his guests and fellow officers. Dr. F. J. McCann, in proposing the guests, described how Lord Macmillan, an LL.D. of seven universities, had served as chairman of the Royal Commission on Lunacy and then had been appointed to preside over the Pharmacopœia Commission. Sir Stanley Jackson, as Governor of Bengal, had proved his ability to stand up to bullets as well as bowling, and as chairman of the Test selection committee had brought good fortune to this country. Sir Stanley remarked that he found the compliments refreshing, for bouquets were by no means thick upon the ground. Mr. Warren Low, president of the Royal Society of Medicine, said that his society had now more than 5000 fellows and 170,000 books in its library. But size was not everything. He recalled a conversation between a bishop and a shepherd who said he had 500 sheep. "Ah," said the bishop, "I too am a shepherd but count my flock in tens of thousands." "Mon," said the shepherd, "that must be an awful responsibility in the lambing season."

Association of Surgeons of Great Britain & Ireland

A surgical scholarship of the value of £350 will be awarded in November by the association to a candidate who wishes to pursue a definite line of research or to study surgery in specified clinics either at home or abroad. Further particulars will be found in our advertisement columns. The honorary secretary of the association is Mr. Julian Taylor, 65, Portland-place, London, W. 1.

British Social Hygiene Council

This council, acting with the Conference of British Missionary Societies, has organised a conference on official and non-official coöperative action in combating traffic in women as suggested by the League of Nations inquiry in the East. The conference will be held in the London School of Hygiene and Tropical Medicine, Keppel-street, W.C., on Wednesday, July 25th. Lord Lytton, the chairman, will open the morning session at 10 A.M.

North Devon Isolation Hospital

A joint isolation hospital, serving nine contributory authorities, all in North Devon, has been opened. The building, which has cost £17,000, has accommodation for 30 patients.

Naval Sick Berth Staff

At a meeting recently held under the presidency of Surgeon Vice-Admiral Sir Reginald Bond, a central council of the Royal Naval Sick Berth Staff Associations at Portsmouth, Plymouth and Chatham was formed under the patronage of Admiral of the Fleet, Sir Roger Keyes. These associations seek to provide death and invaliding benefits for the sick berth staff, and to assist them in obtaining employment on discharge from the Service. Each will still manage its own financial affairs, but with the assistance of a central council it is considered that the employment question will be more forcibly brought to the notice of the medical and general public. The royal naval sick berth staff are trained men who act as nurses in the royal naval hospitals, and on ships in the Navy. They have to pass examinations for promotion, and are discharged to pension after 22 years' service. They have considerable experience in responsible positions. Many have qualified as masseurs, radiographic, laboratory, electro-therapeutic, and operating theatre assistants. All have experience in dispensing, and store-keeping, as well as surgical, medical and mental nursing, and are said to be qualified to fill various situations in hospitals, clinics, institutions as surgical assistants, or as assistants to medical men. Surgeon Vice-Admiral R. W. B. Hall, medical director-general, is a vice patron, while Sir Reginald Bond is the president of the council. Surgeon-Captain Montague Knapp, c/o Medical Department, Admiralty, London, S.W. 1, is the representative president who will be glad to furnish any further information.

There will be a meeting at the Mansion House, London, under the presidency of the Lord Mayor, on Wednesday, July 18th, at 4 P.M., when the Duchess of Atholl and Sir John Martin Harvey will speak on behalf of the Robert Jones National Memorial. The Lord Mayor will be supported by Mr. Rudyard Kipling and Lord Moynihan.

The American Association for the Study of Goitre has awarded to Mrs. M. A. B. Brazier, Ph.D., B.Sc., the Van Meter prize of $300 for the essay entitled the Impedance Angle Test for Thyrotoxicosis. A leading article on the Measuring of Thyroid Dysfunction, using Mrs. Brazier's method as a text, will be found in THE LANCET of Sept. 30th, 1933, where her work was first published. A later paper by Dr. Brazier and Dr. F. M Grant appeared in our issue of Jan. 20th of this year.

Morland Clinics, Alton

On July 7th, at a garden fete held at Morland Hall in aid of the Morland Hall cot fund at the Treloar Cripples' Hospital, Lady Radnor opened the new west wing of the clinics. It will be possible in the new wing to give natural sun treatment to the patients in their own rooms without the necessity of wheeling them onto the adjacent balcony. The Morland Hall cot is maintained by contributions of patients at the clinics and their friends.

Order of St. John of Jerusalem

The following promotions in and appointments to the Venerable Order of the Hospital of St. John of Jerusalem have been sanctioned by the King :—

As Knight of Justice.—Lord Moynihan and Dr. A. M. Ware.

As Knight of Grace.—Hon. J. H. King, M.D., Colonel H. A. Bruce, F.R.C.S., and Sir Frederick Norton Kay Menzies M.D.

As Commander.—Capt. R. J. Isaac, Dr. R. E. W. Wodehouse, Lord Horder, and Dr. W. Hutton.

As Officer.—Dr. F. B. G. Holmes, Dr. H. E. Gibbs, Dr. C. H. Tewsley, Major-General R. B. Ainsworth, Colonel R. C. Wilmot, Dr. W. D. Kirkwood, Colonel H. V. Prynne, Dr. G. Thornton, Dr. C. H. Francis-Williams, Dr. P. R. Bolus, Dr. G. B. Peat, Major W. Nunan, Dr. R. L. E. Downer, Dr. A. Heys, Dr. F. O'B. Ellison, Dr. W. N. West-Watson, and Dr. Phyllys P. Pigott.

As Associate Officer.—Dr. Dhanjibhai Hormasji Mehta.

As Serving Brother.—Dr. H. J. Slane, Dr. G. L. Pierce, Dr. S. B. Turner, and Dr. E. P. Dickin.

Dr. Bernard Hollander Memorial Meeting

At a meeting held on June 12th, at Essex Hall, London, Dr. H. J. Norman, speaking of the medical side of Dr. Hollander's activities, recalled his remarkable erudition and the fact that he seemed to require less than the ordinary amount of sleep. The result was that he was able to undertake much literary work, in addition to attending to a very busy practice as a mental specialist. Mr. J. P. Gilmour and Mrs. Stackpool O'Dell spoke of Dr. Hollander's work in connexion respectively with rationalism and phrenology. A resolution was carried to the effect that a Bernard Hollander Memorial should be established, and a preliminary committee was formed to this end.

International Congress of Radiology

The fourth International Congress of Radiology will take place at Zurich, Switzerland, from July 24th to 31st. At the opening meeting the methods adopted by different countries in their campaign against cancer will be reported on. In all about 400 lectures and reports will be given, and the greater part of them will deal with X ray diagnosis. The first Congress of Radiology was held in London, the second in Stockholm, and the third in Paris in 1931. Delegates from at least 30 countries will attend this year's congress, and the guests of honour will include Sir George Buchanan (president of the cancer commission of the League of Nations) and M. F. G. Boudreau (director of the health section of the League). During the congress latest technical equipment for radiology and electrical treatments will be exhibited.

Research on Tuberculosis

The Medical Research Council announce that they have made the following awards of Dorothy Temple Cross fellowships for 1934–35, under the terms of the benefaction in that name for research fellowships in tuberculosis : William Sayle Creer, M.B. Liverp., Lady Jones orthopædic research fellow in the University of Liverpool ; Alfred White Franklin, M.B. Camb., M.R.C.P. Lond., chief assistant to the children's department at St. Bartholomew's Hospital ; Philip D'Arcy Hart, M.D. Camb., M.R.C.P. Lond., assistant physician to University College Hospital ; Arthur Landau, M.B. Capetown, M.R.C.P. Lond., house physician at the Brompton Hospital ; Alastair Hamish Tearloch Robb-Smith, M.B. Lond., senior demonstrator of morbid anatomy at St. Bartholomew's Hospital. Dr. Robb-Smith's fellowship is tenable in Germany : the others at centres in the United States. The fellowship awarded last year to Dr. G. Gregory Kayne for work at centres in Europe has been renewed for a further period of six months.

The Royal College of Physicians of London invites applications for the Prophit scholarship from qualified medical practitioners with some experience of tuberculosis. The scholar will be responsible for the conduct of a survey into the incidence and progress of tuberculosis in selected sections of the community, by clinical examination and tuberculin testing, over a period of years. Further particulars will be found in our advertisement columns.

International Congress on Chronic Rheumatism

A congress was held at Aix-les-Bains from June 28th to July 1st, Prof. Fernand Bezançon presiding. Some 350 medical men attended, and official delegates were present from 20 countries. The subject discussed was rheumatoid arthritis, one day being devoted to pathology and ætiology, another to symptomatology and to clinical diagnosis, and another to therapeutics. Prof. Bezançon and Dr. Mathieu-Pierre Weil (Paris) described in detail the clinical picture originally presented by Charcot. Subsequent speakers, including Prof. Mouriquand (Lyons) and Prof. Roche (Geneva), discussed the relation of endocrine factors, infection, constitution, and the autonomic nervous system to the disease. Prof. F. Coste (Paris) reviewed the evidence on which the various theories of infection have been based, with special reference to the streptococcus, the gonococcus, and the tubercle bacillus. A great variety of different conditions was referred to under the title of rheumatoid arthritis, but the tendency of the speakers was to ascribe the clinical picture of this disease to the way in which the individual reacts to a variety of extraneous factors, rather than to a specific infection or metabolic upset. Dr. Francis Bach (London) emphasised the general decalcification of bone as one of the early pathological changes in rheumatoid arthritis. Dr. Gilbert Scott (London) described the bone changes visible in radiograms in cases of rheumatoid arthritis, and the diagnosis by this means from osteoarthritis, gout, and other conditions. Prof. Abrami (Paris) discussed the varied clinical forms of the disease, and Prof. Marañon (Madrid) its differential diagnosis. Dr. R. J. Weissenbach (Paris) and Dr. F. Françon (Aix-les-Bains) spoke on prognosis, and Prof. Kahlmeter (Stockholm) on the changes in the blood found in this disease. In connexion with treatment Sir William Willcox outlined the part played by focal infection in the genesis of rheumatoid arthritis, and the technique of its treatment by vaccines. Prof. Rathery (Paris) dealt with drug treatment and chemotherapy, Prof. Gunzburg (Brussels) with physiotherapy, Prof. Paul Mathieu (Paris) and Dr. Loring T. Swaim (Boston) with orthopædic treatment, and Prof. Leriche (Strassburg) with the role of surgery. The latter stressed the value of parathyroidectomy in the treatment of rheumatoid arthritis, and discussed the indications for arterial sympathectomy and arthroplasty. During the congress the new thermal baths were open for inspection, and the various methods of physical treatment available at Aix-les-Bains were demonstrated. The success of the congress was largely due to the efforts of the secretaries, Dr. Mathieu-Pierre Weil, Dr. F. Françon, and Dr. J. F. Forestier.

ADDRESSES AND ORIGINAL ARTICLES

VIRUSES IN RELATION TO THE ÆTIOLOGY OF TUMOURS *

By C. H. Andrewes, M.D., M.R.C.P. Lond.

MEMBER OF SCIENTIFIC STAFF, NATIONAL INSTITUTE OF MEDICAL RESEARCH

In the preceding lecture I put forward reasons for supposing that viruses might be ætiologically related to tumours. These fell under two main headings: first, viruses have been shown to cause tumours in birds; secondly, the proliferative changes produced by some viruses in cells make it not difficult to imagine that they could give rise even to true new growths.

Some Objections to the Virus Hypothesis

The virus hypothesis of cancer is, however, open to a number of very obvious objections, some of which we must proceed to consider.

NON-INFECTIOUSNESS OF TUMOURS

In the first place, tumours are not infectious. There is no evidence of any value that a tumour either of man or animal is acquired as a result of contact between one individual and another. I say this notwithstanding the vast literature which has accumulated on the subject of so-called cancer houses and, as regards mice, of cancer cages. Cancer is such a common disease that apparent instances of infection are bound to crop up simply as a result of coincidences or of causes other than infection with a cancer parasite. Exceptions must be made in favour of infectious warts and the transmissible venereal lymphosarcoma of dogs, neither of which is generally admitted as a "typical" tumour. Nor am I considering the very rare instances in which actual inoculation of tumour cells may have occurred.

The fowl tumours, which are certainly due to an extracellular agent, show no more evidence of infectivity than do the mammalian tumours. Rous and other workers since have fed fowls on tumour material and have attempted in other ways to obtain evidence as to possible modes of infection, but always in vain. Furthermore, when sporadic tumours appear in a flock of birds, the successive tumours which arise may be of very different histological types. Thus four successive spontaneous tumours appearing amongst the fowls on the Medical Research Council's farm at Mill Hill were a spindle-celled sarcoma, a polymorph-celled sarcoma, an osteochondro-sarcoma, and a tumour probably derived from muscle cells.[33]

Borrel[54] first advocated a virus theory of cancer because he thought there was evidence of infectivity of tumours, but to-day this evidence is discredited and advocates of the theory must adhere to it not because of but in spite of the data concerning infectiousness.

To produce any infection one requires at the least three things—a host, a parasite, and a set of circumstances permitting the parasite to infect the host. In many instances the importance of this third factor appears more striking than the mere bringing together of host and parasite—it is so with tuberculosis, with amœbic dysentery, and with tetanus. If tetanus were due to a virus and not to a cultivable bacterium, there would be but little more evidence of its parasitic origin than is available for cancer. Again, most cases of malignant endocarditis are caused by infection of the heart valves with an ordinarily harmless saprophytic streptococcus; no connexion can be traced between one case of the disease and another. Indeed, there is no direct connexion: a third factor such as I spoke of is all-important in the pathogenesis of the condition. Clearly then, a disease of parasitic origin need not be demonstrably infectious, and this objection to the virus theory of cancer cannot be stressed unduly.

MULTIPLICITY OF VIRUSES

Tumours are of many degrees of malignancy, of many types of tissue, of many species of animal. Pathologists have naturally recoiled at the thought that each of these different tumours might be caused by a different virus. Some tumours are extremely rare and one could scarcely imagine a virus which gave evidence of its existence only once or twice in a generation. Yet it seemed equally unlikely that one parasite could cause all types of tumours and that yet in the case of propagable tumours of animals each should remain true to type on transplantation. Gye's attempt to solve this dilemma will be discussed later.

Fowl tumours resemble those of mammals in their diversity of type, and it seemed, therefore, pertinent to inquire whether there was evidence that different growths of the fowl were caused by many different viruses or by one virus. I have sought to solve this problem by serological methods.

Most viruses evoke the production of antibodies which are demonstrated by their power of neutralising the virus in question when mixed with it in vitro. Complement-fixing and other antibodies may occur also but the neutralising properties are, with viruses in general, the easiest to demonstrate. Neutralising antibodies can be shown to be formed against fowl-tumour viruses; they occur in the largest amounts in the sera of fowls which have borne certain chronic tumours for at least five months.[55] Normal fowls, particularly as they grow older, may develop in their sera varying amounts of similar neutralising properties. Usually such sera are not very active, and in only a very small percentage of birds are they as potent as the sera of birds with chronic fibrosarcomata. The antibodies in fowls with a slow-growing fibrosarcoma (MH1) were found not only to be capable of neutralising filtrates of the homologous tumour but also to be active against the viruses causing other tumours of different histological types, the Rous No. 1 spindle-celled sarcoma, three fibrosarcomata (BS1, RF4, and RF11), and an endothelioma (MH2).[56] Rous No. 1 was, however, always more readily inactivated than the others. But Fujinami's tumour, another rapidly growing sarcoma, histologically exactly like Rous No. 1, was not neutralised. The few potent sera from normal birds acted like those from the fowls with fibrosarcomata: they neutralised Rous No. 1 most readily, Fujinami's sarcoma not at all, and the other tumours mentioned to an intermediate degree. It is likely, therefore, that the antibodies in the birds with chronic tumours represent only an enhancement of a property occurring to a varying degree in normal birds. The neutralising agent has the properties of other antiviral antibodies[57] and is unlikely to be the same as the inhibitor described by Murphy[58] as occurring in slow-growing fowl tumours and elsewhere. The results so far obtained indicated that viruses

---

* The second Oliver-Sharpey lecture for 1934, delivered before the Royal College of Physicians of London on May 3rd. Lecture I. appeared in our last issue.

causing different types of fowl tumour were, if not identical, at least closely related antigenically.

Further light was shed by preparing sera in species other than the fowl. It was found that many fowl tumours would grow temporarily in the pheasant and then regress [59]; and these pheasants could be hyper-immunised and yielded potent neutralising sera. Such sera were found to be more specific than the fowl sera. Though cross-neutralisations occurred, antibodies from a pheasant immunised with one tumour were always much more active against filtrates of the homologous tumour than against those of another, even though the tests with fowl sera had shown that the two tumour viruses were closely related.[56] It seemed reasonable to suppose that two fowl-tumour viruses might have an antigenic group in common and might each have in addition a specific antigenic grouping of its own. Experiments on active immunity in pheasants confirmed the suggestion of an antigenic relationship between different viruses.[60] The Rous No. 1 sarcoma almost invariably produced fatal tumours in pheasants; other tumours, as just mentioned, commonly regressed. Pheasants hyper-immunised with material from such tumours were completely or relatively immune to the more malignant Rous No. 1, and such immunity was shown not to be accounted for by immunisation by fowl protein.

As already mentioned, the various fowl sera studied showed no neutralising power against Fujinami's virus. Sarcomata caused by this virus when grown in adult ducks commonly regress, and these birds can then be hyper-immunised just as can the pheasants injected with the Rous and other viruses. The anti-Fujinami sera prepared in the duck are most active against the Fujinami virus but also show some neutralising power against Rous and the other tumour viruses. It appears, therefore, that even the Fujinami virus has some antigenic relation to the others studied, although the connexion is a more distant one than between the Rous and those related to it (MH2, BS1, RF4, RF11).

The work of Gye and Purdy with antisera prepared in mammals confirms these results.[33] Antisera made by immunising goats with tumour extracts confirm the existence of a sharp antigenic distinction between the Rous and Fujinami viruses; but results obtained with the sera from immunised horses suggest that there is after all something in common between these two viruses antigenically.[11]

Studies along these lines have clearly not provided as sharp an answer as one could have hoped for. Serologically the various fowl-tumour viruses are neither identical nor entirely distinct. They seem rather to constitute a group of agents, some closely, some more distantly related. Very similar findings are met with amongst groups of allied bacteria which are shown to possess both group and specific antigens giving rise in the inoculated animal to corresponding group and specific antibodies. Of particular interest is the fact that the bacteriophages attacking the intestinal bacteria may also be classified into broad serological groups: minor antigenic differences are present here also among the individual members of each group.[61] [62]

SPECIFICITY OF FOWL-TUMOUR VIRUSES

One may approach in another way the difficulty presented by the remarkable individuality of every tumour. Everyone knows what extraordinary diversity there is amongst human tumours; and the same applies to the transplantable tumours of the mouse and rat. These maintain their individual characteristics from generation to generation, and one is not unduly surprised, knowing that the cells of the animal body may vary in any number of ways and that the transplantable tumour is merely continuing to reproduce the characters of the cells which are transplanted. But when one finds fowl tumours, transmissible by a cell-free agent, showing the same extraordinary diversity from tumour to tumour and the same constancy of characters when a single tumour is propagated in series, one naturally has to stop and think. No one, I think, can be blamed for being reluctant to believe in the virus theory of cancer when he is confronted with facts such as these.

Attempts at Reconciling Apparently Conflicting Facts

Those who have, within recent years, attempted to construct theories about tumours may be divided into two categories. First, there are those who have based their theories on the known facts about mammalian tumours and have ignored the avian sarcomata or else brushed them aside as inconvenient anomalies. Secondly, we have those who have faced the fact that tumours do occur in birds as well as in mammals, and have tried to frame a theory which shall be applicable to the tumours of both these orders of the animal kingdom. We need only consider those who fall into the second category, and see how they have attempted to explain the existence side by side in the world of filtrable fowl tumours and non-filtrable mammalian cancers, and how they have sought to account for the presence of a virus-like agent in fowl tumours which otherwise behave in a way so very unlike an infective disease.

1. *Filtrability of fowl-tumour cells.*—Many of our difficulties would be resolved if it could be supposed that very minute forms of the fowl-tumour cells occurred and that these could pass through filters or survive in desiccated tumour tissue and initiate new tumours when inoculated into a fresh host. The difference between mammalian and avian sarcomata might thus find an explanation. Unfortunately for this view, it has been impossible to demonstrate these supposed minute cells in filtrates: indeed it seems certain that the active agent is below the limits of resolution of an ordinary microscope. It is thus not only smaller than the smallest known cell of a higher animal, but very much smaller, smaller even than a bacterium. The filtrable cell theory, which was frequently put forward after Rous's discovery of a filtrable fowl tumour, has consequently been abandoned even by those who at one time advocated it.[63]

2. *Possibility of growth of a tumour cell from a small fragment.*—Since it has become clear that tumour cells could not themselves be filtrable, it has been suggested that a cell nucleus or a minute fragment of a cell nucleus might have the power of passing a filter and duly growing again into a complete cell.[64] Since comparatively small injuries to the nucleus will kill a cell, such a theory cannot appear very attractive to a biologist. The point might, however, be argued were it not for the existence of such tumours as Fujinami's sarcoma.[50] A filtrate of this fowl tumour can infect both fowls and ducks, and immunological tests show that the resulting tumour is formed in the one case of fowl, in the other of duck cells. No one can seriously maintain that a minute fragment of a fowl cell nucleus can ever grow up into a duck cell. Further discussion of this theory is therefore needless.

3. *The gene theory.*—"Gene" is the term used by geneticists to indicate the unit in the chromosome which carries a hereditarily transmissible character. It has been suggested by Lockhart-Mummery [64] and

others that a gene might become wild, loose from the chromosome which is its natural environment, and imprint its character on fresh cells with which it came into contact: such a theory has been put forward to explain the nature of viruses in general, including bacteriophages as well as those of tumour agents. It is urged that the size allotted by the geneticists to the gene is of the same order as that of viruses, and that the existence of a gene is not confined within the limits of a single species, as is proved by the occurrence of hybrids. It is difficult to argue positively about the possible behaviour of a biological agent which has never yet been shown to exist in a free state. Nor can one readily deny that a tumour agent *may* have similar physical properties to a gene, when the latter are purely a matter for conjecture. There has, however, been no suggestion, as far as I am aware, that a gene can act as an antigen, as a tumour virus can, in the animal in which it exists. In our present state of knowledge it seems wiser on the whole to confine our speculations to less fantastic channels.

4. *Theories which postulate that the tumour agent is a cell-product.*—We are left with two possibilities: the agent may be a small living micro-organism or a cell product which can stimulate another cell to unlimited proliferation and at the same time to the elaboration of more of the same cell product. The latter view has a number of advocates, of whom Boycott [65] and Murphy [66] have put forward the clearest arguments. The view is much worthier of consideration than the three we have already been able to dismiss. It seems most profitable to consider side by side the views that the tumour agent is a virus and that it is a cell product. It will be evident that a number of facts tell strongly in favour of its virus nature. Let us first see, then, what Boycott, Murphy and their followers are "up against" when they try to account for the agent as a cell product.

EVIDENCE FOR THE VIEW THAT THE FOWL-TUMOUR AGENT IS A VIRUS

There is no time now to discuss the question of whether viruses in general are small organisms; I am, for purposes of this discussion, considering a virus as a living micro-organism.

(*a*) The tumour agent is capable of unlimited multiplication, but, like other viruses and some higher organisms, only in the presence of living cells either in the intact animal or in tissue cultures.

(*b*) It causes the production in the infected bird of antibodies which, as already discussed, show group and specific affinities like those which characterise related groups of bacteria.[56] These antibodies behave in most ways like antibodies to other viruses.[57]

(*c*) Viruses vary in their resistance to chemical and physical agencies. The fowl-tumour agent resists heat, acidity, desiccation, and a variety of disinfectants much as viruses in general do. Gye and Purdy have pointed out the close resemblance of the Rous virus and the organism of bovine pleuro-pneumonia in their inactivation by acriflavine.[33]

(*d*) Many fowl-tumour agents can infect birds other than the fowl. Filtrates of Rous No. 1 sarcoma and several other tumours, including the MH2 endothelioma, will produce tumours in pheasants [59]; and Fujinami's fowl myxosarcoma will infect ducks, a species widely remote from fowls. It is worth recalling in this connexion the hare sarcoma of von Dungern and Coca [67] which was transmissible to rabbits.

(*e*) The fowl-tumour agents show evidence of adaptability. For a time after its discovery the Rous No. 1 sarcoma was transplantable only in blood relations of the Plymouth Rock fowl in which it had spontaneously occurred. Later, growth was found to be possible in other Plymouth Rocks and, still later, in any breed of fowl.[1] Now, after many years, it has been found to be transplantable to the pheasant also.[59] Except for this last stage, transmission to an alien species, this is the sort of behaviour one is accustomed to find amongst mammalian tumours which are transplantable only by means of cells. One is not surprised that living cells can gradually be accustomed to a more and more foreign environment; the occurrence of similar behaviour in a tumour transmissible by cell-free extracts seems to imply that the tumour agent also becomes in course of time adapted in the same way. It may also be mentioned that Fujinami [50] succeeded in growing his fowl myxosarcoma in ducks only after years of effort.

(*f*) The size of the tumour agent is evidence in favour of its living nature. My colleague, Dr. W. J. Elford, has prepared a series of graded collodion membranes, the pores of which can be measured with some accuracy and for a given membrane are extremely uniform.[68] With their aid he, with various collaborators, has estimated the sizes of a number of viruses: their diameters apparently range from about 150 mμ—or more than a tenth of 1 μ—in the case of vaccinia [69] down to about 10 mμ—or one-hundredth of 1 μ—for the virus of foot-and-mouth disease.[70] Filtration experiments with the Rous virus have proved difficult because of the sticky material which is associated with the virus in filtrates, but we have now succeeded by a new method in obtaining virus of high titre free from almost all detectable protein. Attempts to estimate the size of the virus in this purified material are still incomplete, but we can already say with some confidence that the virus is of the order of size of the larger rather than the smaller viruses previously measured.

BOYCOTT'S VIEWPOINT

Boycott and Murphy are alike in suggesting that the Rous agent is not a virus, but they reach a common position by arguing along rather different lines. Boycott [65] in 1928 suggested that there was perhaps no sharp line of demarcation between the living and the dead in nature. Each of the facts adduced in support of the living nature of viruses in general—and of the Rous virus in particular—could be paralleled in the world of admittedly inanimate objects. Thus other things than living organisms appear to multiply. For instance, one might expect a cell-stimulating autolytic product acting upon a tissue culture to lead potentially to the production of more of the same agent. Bordet [71] also has pointed out that the reproduction of thrombin in the clotting of blood bears analogies to the multiplication of an organism. Boycott also refuses to be deterred by the fact that the Rous agent can induce the formation of antibodies in an infected bird. He points out that although such an occurrence is usually evidence of the extrinsic origin of an agent, it need not necessarily be so. For the lens protein of an animal can act as an antigen when injected into the same animal species. Again, almost any antiseptic or physical agent which inactivates a virus such as that of fowl tumours can be shown to have also a destructive action on some unorganised substance.

I know of no one criterion by which one can define a living thing: one must in our present state of knowledge judge whether a thing is alive or dead by applying to it a number of criteria. Boycott's ingenuity has revealed a number of analogies to the Rous and other viruses in the inanimate world; but he has had to concentrate on one criterion at a time. I know of nothing but a living organism which can multiply *and at the same time* act as an antigen in the animal which it infests or injures *and at the same time* shows the same range of susceptibility to a whole series of physical and chemical agents as known micro-organisms *and at the same time* shows evidence of adaptability *and at the same time* has a size compatible with organisation of some complexity. As Rous and Murphy [72] wrote in 1912 of the tumour agent, "No single attribute among those determined suffices to show the nature of the agent; yet taken together its characters are those which we associate with micro-organisms."

I should hate to dispute Boycott's theoretical point that the line of demarcation between the live and the dead may be an artificial one; but for practical purposes I maintain that there is a very sharp difference between viruses (including the Rous virus and bacteriophages) on the one hand and the other, apparently transmissible, substances with which they have been compared.

MURPHY AND TRANSMISSIBLE MUTAGENS

Murphy [66] has, very naturally, been impressed with the difficulties of believing that spontaneous tumours can be due to a living organism, difficulties we have already discussed. But unlike Boycott, who doubts whether viruses in general are alive, Murphy seeks to separate off from the other viruses certain agents to which he would apply the name "transmissible mutagens." This category would include, I gather, the fowl-tumour agents, such an agent as that causing change of type amongst pneumococci and possibly also plant mosaic viruses and bacteriophages. The characteristics of a transmissible mutagen are, first, ability to direct the specific differentiation of the cell into an abnormal channel and secondly, of course, transmissibility. It seems a far cry from cancer to types of pneumococci, but we must diverge for a moment to see why Murphy brings the pneumococci into the story. The successive discoveries of Griffith,[73] Dawson,[74] and Alloway [75] have revealed that a product of one type of pneumococcus—let us say of type I.—can change, for instance, a type III. organism into a type I. in vitro, usually through the intermediate stage of an avirulent, rough organism. From the type I. so obtained one can extract more of the same product, which is capable of converting more type III. pneumococci into type I., and so on. The product thus appears to multiply when in contact with living pneumococci, and, according to Murphy, its action in changing the pneumococcus type is strictly comparable with that of the agent which causes fowl cells to become malignant. From our earlier discussion of Boycott's views, it will, however, be obvious that the pneumococcus type-switching agent only has in common with the Rous virus one property of a living thing—power of multiplication. So far as has been shown, it possesses *none of the other* properties on which I have laid stress; and the analogy with the Rous virus does not therefore appear to me particularly striking.

In a series of papers Murphy [66] and his co-workers have emphasised differences between the Rous virus and viruses in general. They maintain that the Rous agent can be purified by chemical manipulations which would be fatal to a living thing; that antigenically it does not behave like an organism, and that it differs also in other respects, such as in its high resistance to inactivation by ultra-violet light. By precipitation and solution in ways which I have no time to discuss in detail, they obtained a tumour agent of considerable potency yet free from demonstrable protein. Murphy says "it is hardly conceivable that the active fraction I have thus succeeded in obtaining, a substance purified by repeated precipitations, could carry with it through all these manipulations a living organism or virus." [76] Elsewhere he talks of the purification of the agent "by being repeatedly dissolved in alkali and reprecipitated with acid." [77] Almost every month I see these claims quoted in discussions on cancer and elsewhere in support of the view that the Rous agent *cannot* be a virus. But this "treatment with alkali and acid" which sounds so drastic, actually involves adjustments of pH only within a range of 4·7 to 8—nothing, in fact, which would damage the majority of viruses very seriously. Further, vaccinia virus can be purified by adsorption and elution; or can be carried down on a precipitate by acidifying and then be freed when this is redissolved.[78] In fact, these experiments afford no basis whatever for distinguishing the Rous virus from other viruses. Murphy has also attempted to show that the antigenic behaviour of fowl-tumour agents is out of the ordinary.[79] I have already alluded to the development of neutralising antibodies in tumour-bearing fowls. Further, to one who is familiar with serological work with viruses, Murphy's own experiments on the immunisation of rabbits with purified tumour extracts only serve to emphasise the close correspondence between his work and the findings of workers with other viruses.

Three other differences between tumour-agents and viruses emphasised by Murphy concern what appear to me to be minor points altogether.

(*a*) Sturm, Gates, and he[80] selected for study one physical agent, ultra-violet light, and found, as Baker and Peacock[81] did also, that the tumour agent was more resistant to inactivation by it than were the organisms which they selected to compare with it. It has lately been reported,[82] however, that the resistance of tobacco mosaic virus to ultra-violet light is even greater than that of the Rous virus.

(*b*) Reynals and Murphy [83] reported that the Rous agent was fixed and inactivated by susceptible tissues, but not by those of insusceptible species. In this respect it recalls the fixation of bacteriophages by bacteria. Gye,[11] however, has failed to confirm Reynals and Murphy's finding.

(*c*) The action of the tumour agent is inhibited by certain extracts of slow-growing tumours (inhibitors) which appear to be distinct from true antibodies.[68] Similar substances are reported by Murphy to occur in normal tissues.[84] Some work of Shope's [45] suggests the possibility of a similar sort of action against the virus of filtrable rabbit warts described by him.

To sum up, the two major differences alleged by Murphy between the Rous virus and other viruses have *no existence in fact.* The minor ones appear to me to be no greater than those which could be found between any two viruses having rather different parasitic habits.

Fränkel,[85] on the basis of attempts to purify the Rous virus by adsorption and elution, has similarly sought to place the virus in a category of "virus-enzymes" apart from most other viruses. The derogatory remarks I have made about transmissible mutagens may be taken as applying to virus-enzymes also.

Carrel [13] has suggested that the Rous virus is not a true virus but rather comparable with the bacteriophage. I shall not quarrel with him on this score inasmuch as I consider that the evidence that the bacteriophages constitute a group of living organisms is becoming harder and harder to resist.

I have often been tempted to believe, with Boycott and Murphy, that the Rous agent is a cell product and not a living parasite; but its analogies with other viruses are so striking that I cannot conscientiously disregard them. It is easy to understand the point of view which refuses to believe that the filtrable agent in a spontaneous tumour—or a tar-induced tumour—is a virus. But if the agent has all the properties of a virus, one can go too far in denying that it is a virus simply because it turns up in an unexpected place. If one found something with all the properties of an elephant on top of the Matterhorn, rather than deny it was an elephant one would seek to explain how it got there.

GYE'S TWO-FACTOR HYPOTHESIS

Very different is Gye's attempt to solve the problem; and whatever be the merits of his hypothesis it cannot be denied that his paper,[32] published in 1925, stimulated a world-wide interest in the filtrable fowl tumours which for some years had been undeservedly neglected. Gye suggested that there was one cancer parasite—or at most a small number of them; he could not believe in a different virus for every tumour. To explain the specificity—and the transmissible specificity—of the fowl-tumour viruses, he suggested that the virus by itself could not infect a cell; to do so it must be associated with a second, chemical, factor; this second factor determined the type of tumour which would be produced by the virus. The nature and origin of the second factor was very obscure; but Gye's later work shows that he believes it to be a product of the fowl cells. Put rather crudely, his idea is that a virus linked on to some product of a fibroblast produces a spindle-celled sarcoma, linked to some constituent of an endothelial cell it gives rise to an endothelioma, and so on.

In the work he reported in 1925 he had attempted to separate the two factors in a fowl-tumour filtrate, to show that each by itself was ineffective but that when they were recombined they could produce a tumour. The virus was apparently destroyed by chloroform or acriflavine and the specific factor left; on the other hand, when filtrates were incubated anaerobically in a special culture medium the virus was believed to survive while the secondary factor disappeared. Other workers failed to confirm these experiments of Gye's, and after many years' efforts directed to the perfecting of a fool-proof technique, he himself realised that the difficulty of controlling a number of variable factors made it impossible to obtain reproducible results by his original methods. Nevertheless, he did not abandon his hypothesis but was inclined to believe that the association between virus and second factor was more intimate than he had thought at first, perhaps too intimate for breaking-up and reunion to be accomplished at all readily.

Fresh light has been thrown by his later work with Purdy along serological lines.[33] The prolonged immunisation of goats with Rous extracts yielded neutralising antisera against the Rous virus of considerable potency. But, unexpectedly, neutralising sera could also be obtained when goats were immunised with extracts of normal chicken embryo. The sera obtained in these two ways were not, however, identical. There was evidence that the anti-tumour sera contained two antibodies, one active against the virus, the other an anti-fowl element. The goats immunised with embryo-extract contained in their sera only the second, the anti-fowl antibody. Either antibody could neutralise the Rous virus, but while the antiviral one—like other antiviral sera—acted in the absence of complement, the second one would only neutralise in the presence of complement. The anti-fowl antibody could be absorbed out of a serum by repeated absorptions with chicken embryo: the specific antibody to the virus could not. (See Figure.)

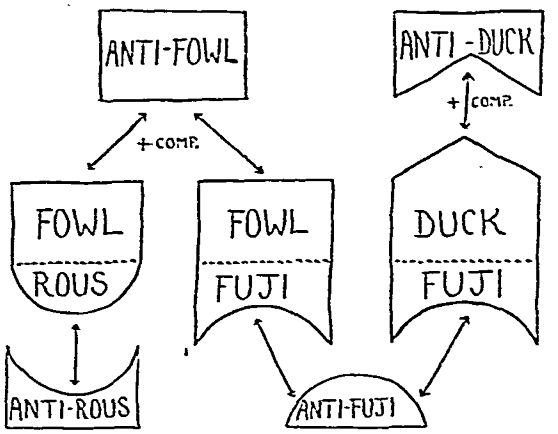

Diagram showing neutralisation of Rous virus, fowl-grown Fujinami virus, and duck-grown Fujinami virus by various goat antisera.

These results, in the opinion of Gye and Purdy, constituted fresh evidence in favour of the two-factor hypothesis. Apparently the active agent could be neutralised by an antibody reacting with either of its constituent parts—the virus element or the fowl element—though for unknown reasons complement was necessary to enable one of the antibodies to act. Additional support for this view was obtained when sera were prepared also against Fujinami's fowl sarcoma; this, as already mentioned, infects both ducks and fowls. When extracts of fowl-grown Fujinami tumours were used to immunise goats the sera obtained were active against the Fujinami virus, as might be expected; anti-fowl sera also inactivated the virus, as it did the Rous, in the presence of complement, but there was no specific cross-immunity between the Rous and Fujinami viruses. Any cross-neutralisation shown by the anti-tumour sera could all be accounted for by the anti-fowl element in those sera. This antigenic difference between the Rous and Fujinami viruses has already been revealed by the experiments with fowl, pheasant, and duck sera.[56]

But if now Fujinami's tumour was grown in a duck and extracts of that tumour were used for similar experiments, behold, the virus was still neutralised by specific anti-Fujinami sera but no longer by the anti-fowl sera! On the contrary, it was now inactivated by anti-duck sera as the fowl-grown tumour had not been.[56] A Fujinami filtrate is thus neutralised by anti-Fujinami-virus antibody wherever the tumour has been grown, and by anti-fowl or anti-duck serum as well according to the bird in which it has developed. This clearly supports Gye's notion that the active agent is of dual nature and that its activity is destroyed if a serological reaction with either moiety takes place.

The neutralisation by anti-fowl serum cannot be explained on the basis that the virus is mechanically carried down on a precipitate and so put out of action, for either neutralisation or precipitin formation may occur in the absence of the other.

Recently Gye has shown[56] that an antibody to fowl serum-proteins has no neutralising power against a tumour virus; extracts containing cell nuclei must be used to obtain a potent antiserum. He feels, therefore, that his second factor is perhaps closely related to the proteins of the cell nucleus itself.

Gye's hypothesis may be right: its claims to be seriously regarded rest, in my opinion, on theoretical considerations and on his later, serological, work rather than on his earlier attempts to separate and recombine two factors. I do not feel, however, that the serological results in themselves prove the truth of his main contention. The neutralisation of the Rous virus with anti-fowl serum does indeed suggest most strongly that the virus is more intimately associated with fowl-protein than are other viruses with the proteins of their hosts. But it remains purely a speculation that this associated fowl-protein determines the specificity of the virus. For all we know to the contrary, the Rous virus may be linked to exactly the same fowl protein as is the MH2 endothelioma virus. One can explain the serological results in other ways than Gye and Purdy do. To give but one example, the action of anti-fowl antibody and complement might be to strip from the virus a protecting protein without which it was too labile to survive.

On purely theoretical grounds also I find the two-factor idea not wholly satisfying. There are many different connective-tissue tumours of the fowl, varying in their rate of growth, in the localisation of their metastases and in other ways. It is true that the Rous sarcoma itself varies from time to time in its rate of growth; these variations possibly correspond to differing amounts of Murphy's inhibiting factor in it. But this and other fowl sarcomata all vary around their own means; one does not turn into another. In most of them cells of the fibroblast-fibrocyte series are presumably "cancerised"; can one believe in distinct specific factors corresponding to a number of slightly different fibroblast-like cells and, if not, has the second factor any value as an explanation of specific differences amongst such tumours? Is it not simpler to believe in a virus or group of viruses which under certain conditions is capable of remarkable specialisation or adaptation?

THE INDIGENOUS CANCER-VIRUS

The last hypothesis which I wish to discuss is not a new one; it is certainly not of my own invention; it may be regarded as being in its main outline the highest common factor of the views of all who have seriously considered the virus theory of cancer, including Rous and Gye. It supposes that when tar or X rays or other agents initiate malignant changes in the cells of a mammal or bird, no virus is introduced from outside; virus is there already. The tar or other agent merely enables the virus to infect or cause pathological behaviour of the cell. As Borrel[54] said in 1910, "l'Organisme normal, non preparé par une cause adjuvante, n'a pas de cellules receptrices pour le virus cancéreux." The properties which must be postulated for a cancer-virus have been discussed recently by Rous.[87] I should like to quote a few of his remarks:—

> "Clearly the supposititious infectious agent can be no ordinary one; . . . a living entity responsible for such growths (tumours) must require for effectiveness a very special basis of predisposition. . . . The agent must be present frequently in the animal body and well-nigh ubiquitous in nature, else tarred mice in all parts of the world could not regularly become cancerous. On the other hand, it can only occasionally reach cells susceptible to its action, or the cells must rarely become susceptible. . . . One may assume that the hypothetical cancer-producing agent leads an existence in or upon the host, and is harmless save on special occasion—like the staphylococci or the colon bacillus—or that it passes in and out of the body frequently without causing harm save when highly unusual conditions provide it with a foothold—as happens with actinomyces.'

In experiments reported in a paper, from the introduction to which I have just quoted, Rous and Botsford[87] show that sheltered mice—mice reared from an early age on as far [illegible] sterilised cages and on [illegible] cancer just as readily when tarred as do mice reared under conditions rather dirtier than usual. They deduce that if a virus is responsible for tar tumours it cannot have reached the mice from outside during the period of tarring, during which the tumours developed.

If critics of the virus hypothesis realised that its upholders considered the ubiquity of the virus as a necessary feature they would not speak of "materials (fowl-tissues) which certainly do not contain a virus" as Murphy[76] does or of "fowls acknowledged to be virus-free" as Haddow does.[68] One cannot certify a fowl free of an invisible virus any more than one can by naked-eye examination certify a milk free from tubercle bacilli. In favour of the presence of a virus in normal fowls is the occurrence of neutralising antibodies against Rous No. 1 virus in normal fowl sera. As already mentioned, in a small percentage of fowls these antibodies are quite potent, but the majority of normal fowl sera will be found to have a little neutralising power—such as is not present in normal human, rabbit, duck, or pheasant sera. This finding is recorded by Pentimalli,[89] by Andrewes,[55] and by Sittenfield.[90] The reported recovery of a tumour agent by Murphy[76] from normal fowl testis may also be of significance.

As to how the predisposing causes could permit a virus to produce its effects different workers have speculated rather differently. Some would believe that only under abnormal conditions could the virus penetrate and infect the cell. Others would rather conceive that the cells were already inhabited by symbiotic viruses and that under the influence of a carcinogenic agent the balance between virus and some controlling mechanism became upset. The last conception has the merit that a greater or lesser tilting of the balance in favour of the virus could be invoked to explain gradations from a wholly benign to a highly malignant tumour. Rous,[87] as quoted above, seems to favour an existence of the virus on the surface of the host or within its alimentary canal; Borrel[54] has emphasised the possible rôle of parasitic worms or acari as vectors of a virus; Cramer[91] has suggested a non-pathogenic intracytoplasmic virus, perhaps entering the nucleus under abnormal conditions. Further knowledge is needed before such speculation can be fruitful, but I should just like to propound one question: where could the supposed cancer virus normally multiply? It seems inconceivable that it multiplies only in tumour cells; one can hardly believe that material from human tumours could ever become widely disseminated; Rous and Botsford's experiments with sheltered mice also tell strongly against this possibility. If not in tumour cells, it may normally multiply within normal cells or outside cells altogether. One cannot press the analogy too far, but it is perhaps pertinent that the known viruses seem all to have a strictly intracellular habitat.

In suggesting that a symbiotic virus might occur in normal cells I am fully aware that supposed symbionts of mammalian cells have been described by many workers in the past. Their claims, particularly when they sought to identify mitochondria with bacteria, have not withstood critical examination. None of them, of course, used optical methods which could have revealed objects of the size which we now know that viruses possess.

The idea that tar and similar agents may act in such a roundabout way as I have suggested may not appeal to those who would prefer a simpler solution of the cancer problem. There are, however, analogies for this sort of finding. Mere raising of the body temperature will produce on the face an eruption of herpes simplex—another virus disease—in 50 per cent. of human beings.[92] Tarring itself will render sensitive to certain strains of herpes virus the skins of guinea-pigs which are normally refractory.[93]

At the conclusion of a recent discussion on carcinogenesis at the Royal Society, Prof. Boycott [94] criticised the conception of a virus which was present in normal cells and ordinarily non-pathogenic. "One had better," he said, "call it something other than a virus." But why not call it a virus if, in fowls, it has the same properties as other viruses? Many symbiotic intracellular organisms are known throughout the animal and vegetable kingdoms. It would be strange if viruses never acted as symbionts. The symbiotic bacteria and fungi of insects afford a particularly useful field for study in this connexion; they are transmitted in some instances through the egg, and many insects cannot be obtained free from them. These symbionts can be seen going through the same life-cycles as their close relations which grow on culture media outside the body.[95]

One point about this indigenous virus hypothesis will not have escaped the watchful critic. Starting from our knowledge of the existence of avian neoplasms caused by viruses, we have come to consider the possibility that tumours of mammals may also be of parasitic origin. We have been forced to conclude that if a cancerous virus is at work here it must be able to act, not on normal, but only on predisposed cells. Yet where fowl tumours are propagable by cell-free agents, there must be a virus capable of acting on normal cells also. Clearly one will have to suppose that fowl-tumour viruses, unlike those of mammals, can become enhanced in virulence as they multiply rapidly in a tumour, so that they can eventually attack cells of normal as well as of abnormal sensitivity. As an alternative to the acceptance of Gye's two-factor theory one can imagine that, whatever were their properties in their old symbiotic days, they are now only able to multiply unrestrainedly in the type of cell in which they have recently become accustomed to doing so. Comparison of the neurotropic and viscerotropic strains of yellow fever virus in rhesus monkeys shows an example of adaptation of a virus to life in different cells of the same host.[96]

Conclusion

The following are the points I have tried to emphasise in these two lectures:—

(1) The filtrable fowl tumours are true tumours, only differing from those of mammals in that a causative agent or agents can be demonstrated apart from the cells.

(2) The properties of this agent correspond so closely with those of known viruses that we are not justified in excluding it from the virus group. Our only grounds for doing so would be its occurrence in spontaneous tumours in circumstances where we should not expect to find a virus: such grounds do not seem to me to be reasonable.

(3) Knowledge of the natural history of other viruses makes it easy to understand how the phenomena of tumour-growth might be produced by a virus: the mechanism of the inception of a spontaneous growth remains, however, a difficulty.

(4) The theoretical objections to the parasitic theory of cancer are no longer tenable in view of the facts of the filtrable fowl tumours.

(5) Discussion of the conception of an indigenous virus has suggested lines along which the parasitic hypothesis might be reconciled with the facts which appear at first to render it so improbable.

The facts and arguments which have been brought together in these lectures afford only indirect and circumstantial evidence in favour of the view that tumours in mammals may be of virus origin. Much more direct evidence is required before we can be prepared definitely to uphold such a theory. But I do venture to make the modest suggestion that on the available facts the parasitic hypothesis merits careful serious attention and not, as in the past, summary dismissal.

"No explanation of cancer," says Rous,[87] "is worthy of attention that cannot be tested." The important recent advances in our knowledge of viruses suggest numerous methods of attack on the cancer problem from the angle suggested by the virus hypothesis. It may be possible before long to obtain reasonably pure suspensions of the Rous virus particles, to agglutinate these with antiserum, to measure their size by filtration or with the aid of the centrifuge, and even to photograph them. Such things can be done with some other viruses which are probably of the same order of size. If fowl-tumour viruses could be investigated in a similar way one could later proceed to study the mammalian tumours along entirely novel lines. In emphasising the importance of attacking the tumour problem in such a way I do not wish to belittle the valuable contributions of the clinician, the statistician, the histopathologist, the organic chemist, and the biochemist. The attack by the virus worker must be considered, not as in opposition to theirs, but as part of one campaign.

In the past the parasitic theory of cancer has been light-heartedly dismissed by many students of tumours who have no personal experience of work with viruses. I dare to hope, therefore, that there may be some value in a contribution to the subject from a virus worker, even though the limitations of his knowledge of many aspects of the tumour problem are all too plain.

THE VALUE OF AEROCYSTOGRAPHY

By Norman Ross, M.B. Leeds
LATE SENIOR HOUSE SURGEON, NORTH STAFFORDSHIRE ROYAL INFIRMARY

(WITH ILLUSTRATIONS ON PLATE)

FOREWORD

By T. H. Richmond, O.B.E., F.R.C.S. Edin., T.D.
HON. SURGEON TO THE INFIRMARY

The following article by Dr. Norman Ross has been written after two years' routine investigation of every case admitted to my wards at the North Staffordshire Royal Infirmary giving a history of possible vesical trouble. The technique he has elaborated is simple, and the time spent has been fully justified by the results. With aerocystography the enlarged lobes of a benign hypertrophy of the prostate give a smooth outline as compared with the irregular outline of a malignant prostate; calculi are easily located; vesical tumours and diverticula are defined; the capacity of the bladder can be demonstrated, and the thickness of the bladder wall appreciated. Much of the success of this work is due to the excellent X ray photographs taken by Dr. John Bromley, the honorary radiologist.

INTRODUCTION

In January of last year I published a paper on the radiographic diagnosis of prostatic enlargement—i.e., radiography of the bladder after it has been injected with air. Since that time I have had ample opportunity of furnishing further proof of the utility of an aerocystogram in the diagnosis of bladder and prostatic diseases.

In my last paper I was mainly concerned with intravesical enlargement of the prostate, and showed the unreliability of rectal examination in establishing a diagnosis. Thus in many cases where there is little or no palpable enlargement of the prostate as felt per rectum, cystostomy might reveal marked sub-trigonal projection; while in other cases marked enlargement per rectum is not necessarily indicative of intravesical involvement. Further, I pointed out that the symptoms of prostatism may be due, not to enlargement of the prostate, but to a "median bar" formation ("contracture of the neck of the bladder" or "prostatisme sans prostate") which demands an entirely different form of treatment from prostatic enlargement.

The value of cystoscopy as a confirmatory means of diagnosis was then discussed and various disadvantages described: (1) owing to contracture of the neck of the bladder it may be impossible to pass the cystoscope; (2) hæmorrhage from the passage of the instrument may cloud the field and prevent distinct vision; (3) gross sepsis may also cloud the field; (4) severe pain may necessitate an anæsthetic (general or spinal); and (5) an expert cystoscopist may not always be at hand. Aerocystography was then offered as an alternative method of diagnosis where the above contra-indications to cystoscopy are present. En passant, I mentioned its value in other types of cases apart from enlargement of the prostate, and it is with these that I wish to deal in the present paper. It must be clearly understood that, except in so far as the above contra-indications to cystoscopy are concerned, I do not advocate the aerocystogram in preference to the cystoscope, which can never be replaced. I merely regard it as a valuable alternative, and one of great importance in the chain of procedures normally carried out in the investigation of the pathological bladder or prostate.

The technique of aerocystography was fully detailed in my first paper. Reduced to simplest terms it consists of (*a*) complete emptying of the bladder, (*b*) injection of air into the bladder through a very small rubber catheter by numerous repeated fillings with a 20 or 50 c.cm. syringe, and (*c*) Potter-Bucky radiography. A low kilovoltage tube is used (40 to 50 K.V. should be quite sufficient), the obliquity of the tube being 15° to 25°. Occasionally a posterior film is taken with the central ray directed obliquely upwards and forwards so as to project the sacrum and coccyx above the field. The objective is merely the production of a sharp contrast between air and solid tissue. Even muscular fasciculation can be brought out to a nicety and, in fact, any structure which interrupts the regular outline of the interior of the bladder can be rendered clearly visible.

I propose here to confine myself to three other conditions, apart from prostatic enlargement, in which we have found aerocystography of great aid in making a pre-operative diagnosis—viz., distinction between simple and malignant prostatic enlargement, the diagnosis of vesical neoplasms, and "prostatic bar obstruction."

DISTINCTION BETWEEN SIMPLE AND MALIGNANT PROSTATIC ENLARGEMENTS

In the aerocystogram a normal bladder shows an outline which is perfectly clear and circular (Fig. I.) with an uninterrupted margin and smooth walls; its capacity, as measured by the number of fillings required, should be about 300 c.cm. When a film is taken at the correct angle, which is the same as for ordinary radiography of the bladder (*15°–25°*), the lower margin should be seen about ¼ in. above the margin of the pubic bones (in a full-sized plate), quite distinct, running laterally within the ileopectineal lines to the iliac bones. The extent to which it rises above the promontoric line depends, of course, on its distensibility. A large bladder is usually ovoid in shape, owing to lateral compression in the pelvis, and may be displaced somewhat to the right by a loaded pelvic colon. As gas in the sigmoid often obscures the interior of the bladder there should be a good preliminary clear-out of the bowel before the radiogram is taken. With benign intravesical enlargement of the prostate (middle and also perhaps lateral lobes) there is an obvious projection at the base of the bladder (*Fig. II. on Plate*). The shadow is definitely conical in shape and quite unmistakable, and its edges are continuous with those of the *inferior* vesical margin. The shadow is almost as dense as the catheter inside the bladder. In the female a some-

what similar shadow may be shown by a cervical fibroid compressing the vesical neck. Calculi are frequently seen in the prostatic substance (Fig. VI.), their situation being thus definitely established, and are thrown into greater relief than in a normal radiogram of the pelvis. The capacity of the bladder depends on the duration of the obstruction. With a short history the organ is usually within the pelvis, but with a long history its capacity may have increased to 600–900 c.cm., so that it rises as high as the fourth or fifth lumbar spine.

With a spheroidal-celled carcinoma of the prostate, again, an unmistakable shadow is cast at the base of the bladder, but instead of the outline being regular it is nodular and perhaps more confined to the one lateral lobe than the other and projects beyond its normal boundaries (Fig. III.). The discovery of a malignant prostate may come as a great surprise where there is nothing either in the patient's history or in the rectal examination to suggest it, but the aerocystographic picture can be relied upon and, when capably interpreted, is almost as trustworthy as the histological examination. It is usually stated that about 2 per cent. of clinically simple prostates are malignant, but this refers only to those which, when examined per rectum, have none of the characteristics of malignancy. In many, at least, of these cases an aerocystogram will reveal the true condition. Neither tuberculosis nor gumma of the prostate will produce a picture anything like it. A multiple calculous prostate may give rise to some difficulty, but usually the calculi can be seen individually within the prostatic shadow, like small seeds. Prostatic cysts have been described, and although they are very rare they may conceivably mislead in interpretation, but I have not had any experience of these; indeed very few have been described.

Lower, in 1915, described a case of difficult urination for eight years. A small cyst about the size of the thumbnail was found protruding from the prostatic urethra into the bladder, and was successfully removed. Ekehorn described a similar case. The man was in hospital twice with acute retention. On each occasion the cyst had been burst by the passage of a catheter and caused no further symptoms until it had grown again. The pathology of these cysts is very obscure, but possibly it is associated with chronic prostatitis, or they may be congenital. Young noted and described nine cases from the literature.

In Fig. III. the essential features of a malignant prostate in an aerocystogram are readily observed: (1) the nodularity of the shadow; (2) the enlargement greater on the right side than the left; and (3) infiltration of the growth beyond the normal boundaries of the prostatic shadow. It is interesting to note how well the phlebolith (to the left of the prostatic shadow in the radiogram) is thrown up by contrast with the air. The bladder wall in this case is thin and smooth, there being no crenation or hypertrophy; it is very distensible, and the capacity is about 600 c.cm., showing a long history of obstruction.

The following is the case-history relating to Fig. III.:—

CASE 1.—The patient, aged 74, was perfectly well until two months before admission to the North Staffordshire Royal Infirmary, when he had a sudden attack of painless hæmaturia. This attack lasted about two days, and passed off just as suddenly as the onset. Since then he had had twelve attacks of hæmaturia, each attack being painless and quite paroxysmal. There had been slight aching in the back, but no pain in the legs and no cachexia. He gave a history of nocturnal frequency of micturition, but only since the onset of the hæmaturia and never before. There was no history of retention or retention with overflow. His general condition was good and there was no anæmia; but the tongue was dry and coated white. The abdomen showed nothing abnormal, and there was no distension of the bladder and no palpable enlargement of the kidneys. The spine and pelvic bones were clear. Per rectum there was no abnormality: the prostate could not be felt enlarged; there was no induration, no nodularity, and no fixation of the rectal mucous membrane. The residual urine measured 6 oz. The urine examination was as follows: specific gravity, 1012; reaction, acid; albumin, + +; polymorphs, + +; red blood-cells, +; numerous epithelium cells; no casts; no bilharzia ova. The blood-urea was 55 mg. per 100 c.cm. and MacLean's urea-concentration test showed definite distress of kidney function.

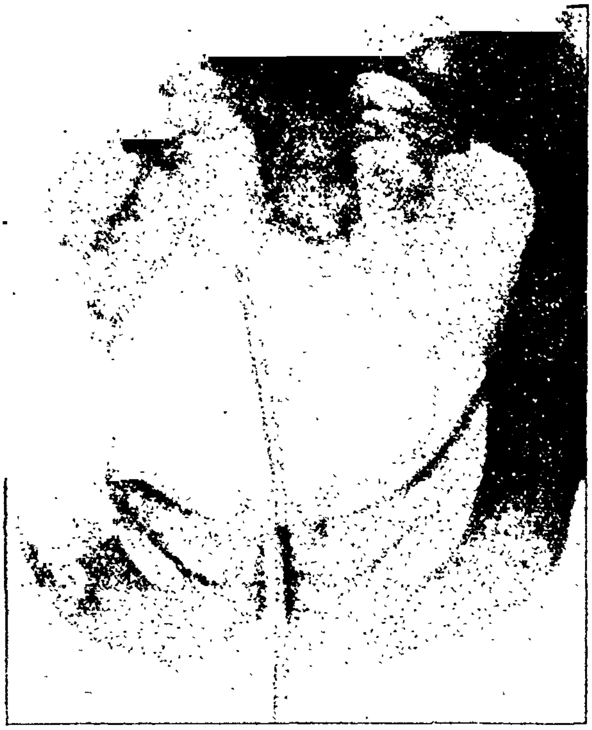

FIG. I.—A normal aerocystogram. Note the well-marked outline of the bladder thrown up by contrast of air with solid tissue.

Hæmorrhage prevented cystoscopic visualisation in this particular case, as did also an intractable cystitis following on repeated catheterisation. The provisional diagnosis from the history was one of papilloma of the bladder. That this presumption was wrong is clearly shown by Fig. III. For confirmation of the diagnosis of malignant prostate a suprapubic cystostomy was carried out. The intravesical projection was hard and nodular to the touch, and was spreading up the side of the bladder wall beyond the lateral margin of the trigone on the right side. There was as yet no ulceration. A portion was taken for section, and Dr. E. C. Myott reported: "The gland has become cystic with proliferating papillomatous projections. The lining cells are massed, and have changed in type. Malignant adenoma."

It was decided to treat this case by interstitial irradiation from within the bladder, and 9 × 1 mg. radium needles (length 27 mm. filtered through 0·5 mm. platinum) were used, being inserted through the suprapubic wound. The man appeared to be making good progress, but three days after operation he unfortunately developed a catastrophic pulmonary embolism and died.

The fact that painless hæmaturia may result from an intravesical enlargement of the prostate is noteworthy. Both simple and malignant enlargements may produce this symptom. Persumably it is due to the rupture of the "vesical piles"—i.e., the submucous venous dilatation resulting from pressure by the growth on the prostatic plexus of veins. With a malignant prostate ulcerating through the bladder mucous membrane, hæmorrhage would also be produced, but owing to the coincident cystitis would not be painless. In the above case the aerocystogram provided the only means of making a certain pre-operative diagnosis.

VESICAL NEOPLASMS

Although in most cases of vesical new growth cystoscopy is satisfactory, it is useful, for the reasons I have stated, to have a second means of diagnosis should it fail. Even a small papilloma can be visualised by aerocystography (Fig. IV.).

The value of this form of diagnosis, however, is not confined to the recognition of the presence of a tumour, for a fair idea of the clinical malignancy or otherwise of the growth can be arrived at, bearing in mind the following essential differences between malignant and benign vesical tumours :—

1. Multiplicity of the growths.
2. Irregularity of their outline on the radiogram.
3. A malignant growth tends to be sessile, whereas a simple papilloma is pedunculated.
4. Infiltration along the bladder wall.

These are the principles which guide us in a cystoscopy or open operation (in the latter, of course, induration is a most important additional factor) and which can also be safely relied upon in interpretation of an aerocystogram, although very often a clinically benign tumour may be histologically malignant.

Villous papilloma may be easily recognised (Fig. IV.). The papilloma may be sessile or pedunculated. Naturally, unless large, the tendrils will not be seen, but these are not necessary for the establishment of a diagnosis. These tumours are rarely situated on the trigone but usually to the outer side of one ureteric orifice ; hence it is not likely that they will be obscured by a prostatic shadow. Often the oblique line of the intramural part of the ureter is visible, as it is raised under the mucous membrane by the muscle of Astley Cooper, and the papilloma may be seen lying close to this. This can be quite clearly seen in Fig. IV. On first appearance it is very similar to the spine of the ischium. The following is the case-history :—

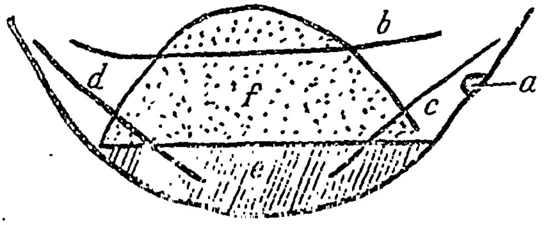

FIG. IV.A.—Diagrammatic representation of Fig. IV. (explained in text).

CASE. 2.—Age 59 years. Twelve months before his admission to the North Staffordshire Royal Infirmary the patient had an attack of scrotal pain, aching in nature, and lasting two or three days. This was unassociated with any urinary disturbance, and after the attack he was perfectly well until a week before admission, when he had an attack of painless hæmaturia lasting three days and then clearing up. There had been occasional pain down the backs of both thighs. Apart from the hæmaturia, micturition was normal, and there was neither frequency nor retention. The bowels were regular, there was no loss of weight, and he was well nourished. The skin was not unduly dry, but the tongue was dry and coated white There was nothing abnormal in the abdomen. Per rectum there was slight enlargement of the prostate backwards. The surface was smooth and the consistence elastic. The median groove was well defined, and there was no palpable enlargement of the vesicles. The prostate was not tender.

A preliminary diagnosis of vesical papilloma was made, and he was admitted to hospital for investigation. His urine was acid, specific gravity 1014, with a faint trace of albumin. The blood-urea was 52 mg. per 100 c.cm., and the urea-concentration test showed no great impairment of kidney function. The aerocystogram, which was later confirmed by cystoscopy (found possible in this case), revealed a number of highly interesting points. In Fig. IV.A can be seen :—

(1) The papilloma (*a*), lying about half the breadth of the superior ramus of the pubes from the ischial spine and similar to it in appearance. It is a typical "long-distance" photograph of a villous papilloma. It lies just outside the crossing of lines *b* and *c*, representing the left ureteric orifice (*b* is Mercer's interureteric bar, and *c* and *d* two sides of the trigone). The papilloma is sessile in type. (2) A marked enlargement of the middle lobe of the prostate. This is regular and well defined, and is obviously a simple senile hypertrophy. (3) Immediately in front of the latter is a fibrous trigonal "prostatic bar," running between the two sides of the trigone and then terminating sharply. A combination of marked prostatic intravesical enlargement and median bar formation is extremely rare. (4) The bladder wall itself is thin and is beginning to dilate. There is no hypertrophy or fasciculation, and the capacity is 300 c.cm.

CARCINOMA OF THE BLADDER

Thomson-Walker classifies vesical carcinomas according to their macroscopic characters into three groups : (1) malignant papilloma ; (2) nodular growths ; (3) infiltrating growths divisible into (i) squamous epithelioma ("chancroid"), (ii) cylindrical epithelioma or adenocarcinoma (this is rare), (iii) spheroidal-celled carcinoma.

Fig. VII. shows a typical carcinoma of the nodular type. There are five growths, indicated by the figures ; 1 and 2 are the largest and most irregular in outline. They are surrounding the trigone, which is itself clear of growth, a rather typical finding ; all are markedly sessile in character. No villi can be seen. The bladder itself is dilated but not hypertrophied ; its capacity is 550 c.cm. There is no enlargement of the prostate. The comparison of the aerocystographic findings with the history of the case from which Fig. VII. was taken is instructive.

CASE 3.—Age 55 years. Admitted to the North Staffordshire Royal Infirmary with a two years' history of recurrent hæmaturia in the form of small clots at the end of micturition. The hæmaturia was painless. During the periods of freedom there was a constant perineal pain, with scalding pain at the end of the urethra during micturition. There was occasional pain down the left leg, no frequency or retention, but much loss of weight. He was a poorly nourished man. The skin was dry and grey, and there was a definite uræmic odour about him. The tongue was dry and coated white. The abdomen showed no distension of the bladder. There was no palpable enlargement of the kidneys. Per rectum the posterior lobe of the prostate was slightly enlarged and smooth. It was not nodular, and there was no vesiculitis or vesicular enlargement. The prostate was not tender. There was no fixation of the mucosa of the rectum, and the consistency of the prostate was soft and elastic. The specific gravity of the urine was 1016, albumin + +, polymorphs + +, triple phosphates + +, nil on culture. The blood-urea was 37 mg. per 100 c.cm. The blood count showed 3,350,000 red blood-cells, 11,000 white cells ; hæmoglobin, 64 per cent. ; polymorphs, 82 per cent. ; transitional and mononuclears, 5 per cent. ; lymphocytes, 12 per cent. ; eosinophils, 1 per cent. ; anisocytosis +.

Suprapubic cystostomy was performed under spinal stovaine and the aerocystographic findings were amply confirmed. These are represented in Fig. VII.A. Two large papilliferous nodules were discovered in the base of the bladder, one about 4 × 3 cm., the other 3 × 3 cm., the larger being above the smaller and to the right. There are also three smaller nodules, each 1 × 1 cm., as shown. Note the relationship of these growths to the ureteric orifices. A section of one of the growths was taken for biopsy, the pathological report being: "Section shows flattened papillomatous projection. No malignant signs found." In spite of this it was decided to treat the condition as clinically malignant. The choice, of course, lies between cystectomy and radium.

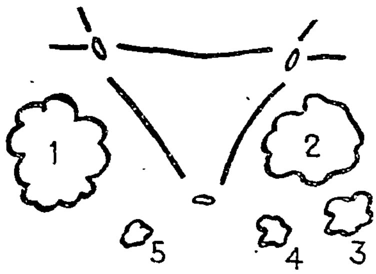

FIG. VII.A.—Diagram illustrating Fig. VII. (see text).

MEDIAN BAR FORMATION

In dealing with this condition in my previous paper I wrote :—

> "We are all familiar with the case of the man who has an unmistakably enlarged prostate when examined per rectum but, on opening the bladder, is found to have either no intravesical enlargement or very little enlargement, but nevertheless has a contracture at the neck of the bladder which is responsible for his symptoms. This is the so-called 'prostatic bar obstruction,' 'contracture of the neck of the bladder,' or 'prostatisme sans prostate.'"

Median bar formation is a definite pathological entity about which much has been written in America during the past 15 years, but which has received scant recognition in British journals. Nevertheless, in approximately 10 per cent. of cases of prostatic disease the symptoms of "prostatism" are associated not with a median lobe hypertrophy but with an atrophy of the gland tissue. Rectal examination in these cases as a rule gives no information except an undue firmness in consistency. Cystoscopy and aerocystography alone will establish the pre-operative diagnosis.

Young and Randall did much to simplify the pathology of this condition. Randall at autopsy examined the bladders of 300 men of ages 10–80 years, and discovered 54 cases of prostatic bar. In 18 of these cases (6 per cent. of prostates examined) the bars were very definite ; in the other 36 (12 per cent.) they were very small. In the large majority of cases the usual lesion consists of a thickening of the median portion of the prostate posterior to the internal sphincter, and takes the form of a definite bar rising up beneath the mucous membrane of the trigone. The mucous membrane is normal, but beneath it there is an extensive fibrosis and, deeper down, glandular tissue (ducts and acini) in a state of chronic inflammation. Occasionally there is a true prostatic hyperplasia. Sometimes the bar consists mainly of smooth muscle, in others it is thin and leaf-like (Mercier's valve). Young describes the bar as follows :—

> "There is usually a slight depression or sulcus on each side of the median bar between it and the lateral margins of the prostate, but in some cases the contour is continuous and the lateral margins of the prostate take part in the fibrosis, so that the condition is a circular fibrotic construction of the vesical orifice ; in such cases the term 'contracture of the vesical neck' is quite appropriate. At times one sees a definite bar or valve anterior to the urethra. It is usually less pronounced than the posterior bar, but in rare cases may be more pronounced and sometimes be responsible for most of the obstruction."

In a good many cases there is a history of obstruction from infancy. Always with median bar formation there is a coincident infectious process, pointing to chronic prostatitis as the probable underlying cause. About one-third of the patients give a history of previous gonorrhœa.

Median bars may be classified as :—

(1) *Fibrous.*—Divided into two types: (*a*) urethral; (*b*) trigonal.

(2) *Glandular.*—Divided into two types: (*a*) hypertrophy confined to the posterior prostatic commissure under the sphincter, producing a thick broad bar ; (*b*) arising from the subcervical glands of Albarran and lying within the sphincteric ring, forming a small prostatic lobule. Occasionally a large intravesical lobe is formed.

The tissue removed by punch operations shows microscopically a round-cell infiltration in 35 per cent. of cases, a chronic fibrosis in 12 per cent., and muscular hyperplasia in 1·7 per cent. (Young.) All are inflammatory with the exception of a small group of congenital cases (2 per cent.). The lesion consists largely of peri- and intra-acinous infiltration with round cells and occasionally cystic dilatation and intra-acinous epithelial growth similar to that seen in hyperplasia of the prostate. The inflammatory infiltration may invade the musculature quite distant from the mucosa and may eventually replace the muscle by fibrosis.

The diagnosis of these cases is based on a history similar in most respects to that of a typical "enlarged prostate," although sexual symptoms are negligible. There is difficulty and frequency of micturition. Per rectum, however, all that can be felt is a small indurated prostate which gives no help, and identification must rely on a cystoscopic examination or on the aerocystogram. I have given above the conditions which may prevent cystoscopic examination (cystitis very frequently complicates this condition), although it must be admitted that with a small meatal glandular bar cystoscopy is of more value, as it could quite easily be missed in an aerocystogram ; further, the catheter might obscure the visibility at the meatus. The radiograms of two prostatic bars are shown, and these are both of the fibrous trigonal type (Figs. IV. and V.). Fig. IV. has already been described. The following is the case-history relating to Fig. V. :—

CASE 4.—Aged 76. Admitted to hospital with a twelve months' history of frequency of micturition, both diurnal and nocturnal (5–6 times during the night). For a week before admission the difficulty had gradually increased, and on each occasion he had passed less and less urine. Every time he micturated he felt that he had not completed the act and emptied the bladder. In other words, he was suffering from the symptoms of prostatism. There was no history of hæmaturia, no drowsiness, headache, or pain in the back, no sexual neurosis, no loss of weight. The bowels were constipated. On examination he was a well-nourished man ; the skin was not dry, but the tongue was dry and coated brown. The abdomen showed no distension of the bladder. There was no tenderness over the costo-vertebral angles and no palpable renal enlargement. Per rectum the posterior lobe of the prostate was only slightly enlarged ; it was indurated but not nodular, and the median groove was well-defined. There was no fixation to the rectal mucous membrane, and no tenderness or fluctuation. The seminal vesicles were not palpably enlarged or tender. The specific gravity of the urine was

1012; albumin +; phosphates +. Blood-urea, 60 mg. per 100 c.cm. MacLean's urea-concentration test showed a maximum concentration of 2·25 per cent. and a minimum concentration of 0·33 per cent.

Clinically, one would have thought a diagnosis of intravesical enlargement of the prostate was fairly obvious—i.e., apart from the absence of marked palpable enlargement per rectum. The aerocystogram was taken as a routine, and with a most interesting result, for it showed a condition which could not have been diagnosed in any other way apart from cystoscopy. Owing to the comparative infrequency of prostatic bars the result was also somewhat of a surprise. The interpretation of this aerocystogram is very easy. The bladder is small, being in "systole" (capacity 150 c.cm.); the wall is not hypertrophied but is mottled from chronic cystitis. No intravesical enlargement of the prostate is made out, but an unmistakable trigonal bar is visible. Its height is about one-ninth that of the bladder as shown in the film, and it lies in the *internal trigone*. *The upper margin is straight and runs from side to side behind the meatus.* The diagnosis is made at a glance, for no other condition can possibly be mistaken for it. Suprapubic cystostomy confirmed the diagnosis. In Fig. IV. and exactly similar condition is seen.

Transurethral surgery, of which we have heard so much recently in this country, was initially introduced for the treatment of median bar obstruction. Young advised a punch, Geraghty a sphincterotome, and Braasch a median bar excisor. With the advent of the high-frequency cutting current, Collings and Wapplers invented for this purpose an electrode which could be used through a direct cystoscope. This instrument has also been used for the division of the dense adhesions which occasionally follow prostatectomy.

SUMMARY AND CONCLUSIONS

(1) The value of aerocystography as an aid to diagnosis of intravesical enlargement of the prostate is confirmed. The disadvantages of cystoscopy in certain cases are reiterated, and the simplicity of the air-in-bladder technique noted.

(2) The interpretation of a prostatic shadow is clarified, and the ease with which distinction between simple and malignant prostates may be made is especially emphasised.

(3) New growths of the bladder are also visualised by this procedure, and an attempt is made to correlate the aerocystographic appearances (corresponding to the morbid anatomy) with the histological anatomy of these neoplasms.

(4) Reference is made to "median bar" formation, and diagnosis by [illegible] in certain types (trigonal bars) is [illegible] meatal bar cystoscopy is a preferable means of diagnosis. The existence of median bars should be more widely known; hence the full description I have given of them. I acknowledge much indebtedness in this matter to the writings of Young and Randall, whom I have quoted freely. This very interesting pathological entity has been elucidated by their work.

(5) Finally, I might add the disappointment we feel that this most valuable adjunct to diagnosis is not more widely known and used. During the 18 months that this diagnostic method has been in use at the North Staffordshire Royal Infirmary it has not failed to help us in a single instance where any of the conditions described above has been present. Exploration of the bladder has always been deferred until the preliminary aerocystographic reading has been made; the justification of a standard routine in its employment has been definitely established.

My sincere thanks are due to Mr. T. H. Richmond and Mr. F. W. Duthie, hon. surgeons at the North Staffordshire Royal Infirmary, for their permission to publish this work. The material has been abstracted from patients under their care in the hospital, and their assistance and advice has been invaluable; to Dr. J. F. Bromley, hon. radiologist, I also owe a debt of gratitude for his radiographic help; and to Sister Jones for her patience and stimulating enthusiasm.

LEGENDS TO ILLUSTRATIONS ON PLATE

DR. ROSS

(*Radiograms by* Dr. J. F. BROMLEY)

FIG. II.—Benign intravesical enlargement of the prostate. Note the hypertrophy and crenation of the bladder wall and the well-marked projection that the median lobe of the prostate makes. The *bladder musculature* is passing from the stage of systole to diastole.

FIG. III.—Malignant prostate. Note the irregularity of the shadow and the marked distension of the bladder wall, which is also very atrophied. There is a well-marked phlebolith to the left of the prostatic shadow. See text for full description.

FIG. IV.—Aerocystogram showing a combination of (*a*) simple papilloma of the bladder, indicated by arrow on right; (*b*) median lobe hypertrophy of the prostate; and (*c*) median bar formation. See text for full description.

FIG. V.—Fibrous trigonal bar formation. The bladder wall is hypertrophied and fasciculated, and in systole. The fluffiness of the interior of the bladder is due to chronic cystitis with alkaline incrustation.

FIG. VI.—Fairly well-marked benign hypertrophy of the prostate with multiple calculus formation. Note the very distended bladder. The fundus has been pushed over to the right, probably by the sigmoid colon.

FIG. VII.—Carcinomatosis of the bladder. Note the irregular masses which are obscuring the base. The bladder is much distended. See text and diagrammatic representation for full details.

DRS. RODGERS, PECK, AND JUPE

FIG. I.—Radiogram showing the leg bones of a child under treatment for tuberculous disease, taken for comparison. At the ends of the bones lines of temporary cessation of growth due to illness show as slightly denser areas, but are easily distinguished from deposits of lead.

FIG. II.—Patient at the time of admission, showing dense "lead lines" at the growing ends of the bones of the leg.

FIG. III.—Patient five months after admission, showing normal bone laid down to the epiphyseal side of the lead lines.

FIG. IV.—Lead lines in bones of forearm on admission.

DRS. PLATT AND OWEN

FIG II.—Radiogram showing rickety changes in bones of forearm, with calcification of arteries.

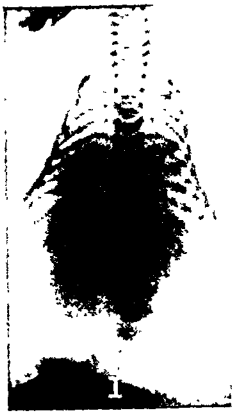
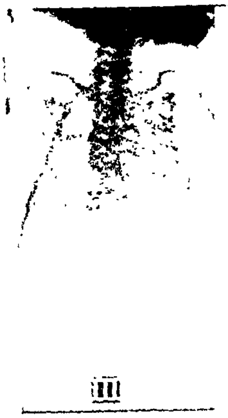
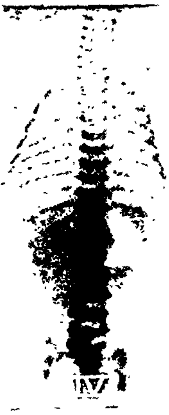
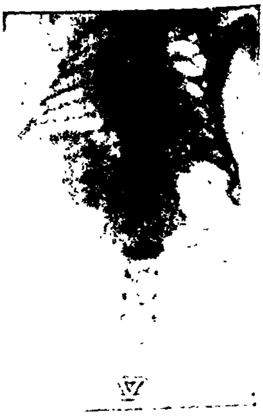
DR. HAJKIS: RADIOGRAPHIC EVIDENCE OF LIVE BIRTH









LEAD POISONING IN CHILDREN

WITH A CASE RECORD

By T. Stanley Rodgers, M.D., M.R.C.P. Lond.
FIRST ASSISTANT AND REGISTRAR IN THE CHILDREN'S DEPARTMENT, LONDON HOSPITAL

J. R. S. Peck, M.R.C.S. Eng.
HOUSE PHYSICIAN IN THE CHILDREN'S DEPARTMENT; AND

M. H. Jupe, M.R.C.S. Eng., D.M.R.E.
ASSISTANT RADIOLOGIST TO THE HOSPITAL

(WITH ILLUSTRATIONS ON PLATE)

The importance of radiography in the diagnosis of lead poisoning in children is illustrated here by a case report, and a brief outline is given of the effects of lead on the body and the clinical aspects of poisoning in children.

Lead poisoning has been known since Hippocrates described a case of lead colic in an extractor of metals some 300 years before the birth of Christ. Cases of poisoning due to contaminated wine have occurred in France for 400 years, and in the early part of the eighteenth century an epidemic of poisoning due to lead used in the storage of cider occurred in Devonshire. In 1839 was published by Tanquerel des Planches the first complete clinical description of lead poisoning based on over 1000 cases, and recently our knowledge of the metabolism of lead has been enriched by the researches of Aub and his associates in America. During the last 25 years, owing to the improvement in industrial hygienic conditions, there has been a great decrease in the incidence of this, the most common, form of industrial poisoning.

White lead, used in the making of face powder, has been a source of poisoning among nurslings in Japan for over two centuries, and, although a form of serous meningitis was recognised in 1901 by Hirota [1] as a definite clinical entity, it was not until 1923 that I. Hirai [2] found the cause to be lead. In Queensland, Australia, the lead used in painting verandah railings is readily powdered by the hot dry atmosphere and has been reported as a cause of many cases of poisoning in children, since Gibson, Turner,[3] and others drew attention to this danger some forty years ago. Now, since the use of lead-containing paints has been limited by law, the incidence of poisoning has been reduced considerably.

In America the first case of lead meningitis to be described was published by Blackfan and Thomas [4] in 1914, and this was followed shortly afterwards by further reports from Strong,[5] Norton,[6] Holt,[7] and others. Since then lead poisoning among children has been recognised with increasing frequency, and in the decennial period 1924–1933 no less than 89 cases have been seen in the Boston Children's Hospitals (McKhann and Vogt [8]). The radiographic changes found in the long bones and described by Park [9] in 1930 have made diagnosis easier and more certain, and no doubt account in part for this increase. John Thompson [10] published in 1925 an article entitled "Peculiar fatal convulsions in four children whose father suffered from lead poisoning." He considered them cases of congenital lead poisoning but there was not sufficient evidence for a definite diagnosis to be made, and plumbism in the child from paternal poisoning is no longer considered a possibility. We have found no other reference to lead poisoning in children in the English literature since 1890, and the case here recorded is the first diagnosed in the wards of the London Hospital. It may be that lead poisoning is not really so rare among children in England but merely that it is overlooked.

Apart from industry, lead poisoning occurs more commonly in children than among adults for three reasons. The young child frequently conveys to his mouth anything he can get hold of, and of the 89 cases mentioned above 72 were between the ages of one and three years. Also pica, or perverted appetite, whether from mental deficiency, ill-health, or habit, has been noticed in many of these cases (Ruddock [11]). Again, children are very liable to suffer from acidosis, and this may precipitate toxic manifestations in a case of latent poisoning. Further, it has been proved experimentally in animals that the young are very susceptible to lead, and in a recent epidemic of poisoning in Boston due to the burning of storage battery cases as fuel, of the 40 cases only 3 were adults although adults and children were equally exposed to the lead fumes (B. Williams et al.[12]).

Lead paint from furniture, woodwork, or toys has been the commonest source of poisoning, and in America, owing to the number of cases of poisoning from this origin, it is no longer used in the manufacture of cribs and the better-class toys. Toys made of lead have not been mentioned as a cause of poisoning, rather unexpectedly, considering how common such toys are. They were the probable source of poisoning

---

LEGENDS TO ILLUSTRATIONS ON PLATE

DR. WILSON

FIG. I.—*Right:* Deep-seated disease which gradually becomes thinner towards lung surface. Spontaneous pneumothorax, shown along the whole of the outer surface of the lung, regular in outline. No fluid in pleural space. *Left:* Peribronchial thickening and fine nodular disease. *Heart:* Slightly to the left.

FIG. II.—*Right:* No sign of spontaneous pneumothorax. *Left:* Almost complete collapse of lung due to spontaneous pneumothorax. Note the two lobes and the absence of pleural or interlobar adhesions. *Heart:* Normally situated.

FIG. III.—Left pneumothorax again developing but not causing complete collapse.

MR. MCFARLAND

FIG. I.—Old ununited fracture treated by modified Lorenz osteotomy and immobilisation.

FIG. II.—Impacted fracture treated by immobilisation.

FIG. III. (Case 4).—Subcapital fracture treated by accurate apposition and immobilisation.

FIG. IV. (Case 5).—Subcapital fracture treated as described above

DR. HAJKIS

FIG. I.—Radiogram of stillborn child. Complete atelectasis. No air in intestinal tract.

FIG. II.—Air in stomach and intestines after five minutes of life. Heart beat for five minutes, and the child made three respiratory efforts. (Spontaneous vertex delivery, but mother had lobar pneumonia.) Routine treatment for asphyxia included Marshall Hall and Byrd's methods and mouth-to-mouth insufflation. Radiogram shows aeration of the margins of the lungs but atelectasis elsewhere.

FIG. III.—Five hours alive. Aeration of right apex and margins, atelectasis elsewhere. No insufflation. Air in stomach and intestines.

FIG. IV.—Stillborn child. Radiogram taken 72 hours after insufflation. Air in stomach only.

FIG. V.—Lungs expanded but less translucent than normal. No insufflation. Air in stomach and intestines.

in our case. Lead foil, food contaminated from kitchen utensils, or water from lead pipes are other less frequent sources. Lead-containing ointments, lotions, plasters, and dusting powders applied to the breasts, and lead nipple shields have caused poisoning in breast-fed infants. In Manchuria lead meningitis was said to be the fourth most common of all causes of death, and the origin of the poisoning was the toilet powder used by the mother (Suzuki and Kaneko[13]). Lead carbonate forms an opaque base, spreads smoothly, and, being cheap, was often used for the inferior grades of powder.

Lead absorbed by the respiratory tract gives rise to rapid and severe poisoning, and has especially to be guarded against in industry. Among children almost all cases have been due to absorption by the intestinal tract, and, though absorption through the skin is possible, it is slow and of little practical importance.

ACTION OF THE POISON

It is probable that lead is conveyed in the blood as colloidal lead phosphate which at the normal pH of the blood is very stable but by slight changes in the reaction, especially towards acidity, is easily converted into the more soluble di-lead salt. In cases of latent poisoning this probably accounts for the sudden development of toxic symptoms during an acidosis induced, for example, by an infection, as in the case described here, or by attempts at "de-leading" the patient. During absorption lead is found distributed throughout the body, but when absorption has ceased, and when there is no symptom of poisoning, it is found mainly in the bones as tertiary lead phosphate and sometimes in the keratin-containing substances, nail and hair (K. Kato[14]). Lead stored in the bones is apparently harmless. Aub[15] has shown that the metabolism of lead and calcium in the body is similar, and on this basis rests the modern treatment of lead poisoning. Factors favouring the storage of calcium in the bones, such as vitamin D and an adequate and balanced phosphorus-calcium intake, will also aid the deposition of lead, and so will be of use in the acute phases of poisoning when lead is widely distributed. In latent poisoning when attempts are made to rid the body of lead, those measures which cause an increased excretion of calcium may be used; of these Aub and Hunter[16] have shown that Parathormone is the most potent, and the liberation of comparatively large amounts of lead by this means, for some unexplained reason, is not accompanied by signs of poisoning. This action of parathormone, however, is found only on the first injection, a second injection causing no further excretion of lead. Acids or acid-forming salts will cause an excretion of lead, which is increased by giving a low calcium diet, while alkalis and potassium iodide have a similar though less pronounced effect without the need of a special diet. Shelling[17] has shown that magnesium hinders calcification and therefore, probably, the deposition of lead, for which reason it should not be given parenterally to cases presenting symptoms of acute poisoning.

Lead is excreted mainly by the bowel and to a less extent by the kidneys; the gall-bladder is also probably concerned in its excretion but only to a slight extent. Lead found in the fæces may have passed through the intestinal tract unchanged, but lead found in the urine proves absorption, and is therefore of great diagnostic importance.

That anæmia is associated with lead poisoning was noted by Laennec in 1831; stippling was described by Ehrlich in 1885, and its relation to plumbism demonstrated by Behrend in 1899, but the mechanism of this change has only recently been made known. Lead changes the colloidal state of the cell surface by a deposition of insoluble lead phosphate and a local production of acid; this causes a shrinkage and hardening of the cell wall which, while making it more resistant to changes in osmotic pressure, makes the cell more brittle and less sticky. The effects of these changes are seen in the resistance of "leaded" cells to low concentrations of saline, and the absence of agglutination frequently found with sera of the various agglutinating groups. The brittle cells, unable to withstand the trauma inflicted in circulation, are readily destroyed, and so is produced a hæmolytic anæmia. To this is due the increase of pigment in the blood, bile, and urine which is sometimes found, and the compensatory erythroblastic reaction in the marrow, evidence of which may be found clinically in the high reticulocyte count of the blood. Lead, always prone to attack the young cells, produces in these reticulocytes a clumping of the basophilic substance of the cytoplasm to which the appearance of stippling is due.

The blue line of the gums is due to a subepithelial deposit of lead sulphide. The circulating tertiary lead phosphate is converted locally into the very soluble di-lead salt by slight changes in the reaction of the tissues, and this combines readily with hydrogen sulphide which diffuses through the gums, being formed from the decaying protein of food material left in the crevices between the teeth. The lead line, as would be expected, is rarely seen when the teeth are kept clean, and is not found in the herbivora.

The damaging effect of lead on the germ cell is well known, producing abortion or weakly offspring. Lead colic is due to its action on smooth muscle. In vitro there is an inhibition of motility and an increase of tone, which explains the constant association of colic and constipation. The primary changes in lead palsy are now known to be in the muscle, such changes as are found in the cord and peripheral nerves probably being the result of paralysis of the muscles supplied. Lead, circulating as insoluble colloidal phosphate, meets the lactic acid of fatigued muscle and is precipitated on the cell surface as lead phosphate by reacting with the inorganic buffer phosphate of the cell; this changes the properties of the cell surface and leads to lead palsy. It has long been known that the muscles most used are those most often paralysed.

In lead meningo-encephalopathy the most important change is an intense cerebral œdema which explains all the symptoms of depression and excitation of the brain found in these cases, and may lead to death from medullary compression, or the ischæmia produced may later result in extensive cerebral atrophy, demonstrated by McKhann in one case by means of an encephalogram two years after the onset of poisoning. This cerebral atrophy is the cause of such nervous sequelæ as mental deficiency, paralyses, and spontaneous movements. In many cases there is evidence of a sterile meningitis in the neck rigidity and increase of cells in the cerebro-spinal fluid, and a proliferative meningitis has been demonstrated post mortem. The cerebro-spinal fluid is under increased pressure, and there is a moderate increase of the total protein. The cell count is nearly always raised, from 20–100 cells per c.mm., but it may be normal.

THE CLINICAL RESULTS

Acute poisoning due to the rapid absorption of large amounts of lead is rare and the symptoms mainly gastro-intestinal, to which are often added signs of cerebral disturbance such as are found in the encephalopathy of *chronic poisoning* (D. D. Stewart[18]). Other of the toxic episodes of chronic poisoning may occur, and an acute hæmolytic anæmia of varying severity has been found in some cases.

The repeated ingestion of small amounts of lead may produce signs of absorption such as a "blue line" on the gums, and changes in the radiological appearance of the long bones, without producing any signs of intoxication. This state of latent poisoning is found more often among adults than in children, the young being relatively more susceptible to lead. The amount of lead absorbed, the pH of the blood, and idiosyncrasy are other factors influencing intoxication.

The disturbance of health produced by chronic poisoning causes such general symptoms as constipation, vomiting, loss of appetite, and irritability, which is often extreme. These symptoms, usually insidious in onset, are found a varying period after absorption has begun. A secondary anæmia is a constant accompaniment, but punctate basophilia, though usually well marked, is not an invariable finding. It occurs in over three-quarters of the cases according to Holt.[19] Evidence of hæmolysis (hæmoglobinuria, hæmatoporphynuria, and increase of bile-pigments in the blood) and of marrow regeneration (reticulocytosis) are sometimes found. The "blue line" though an important diagnostic point is not often seen in children, and Kato reports the occasional finding of blackened teeth and nails in babies in Japan.

The toxic episodes which may occur in the course of chronic poisoning are colic, peripheral limb palsies, papillœdema and ocular palsies, and meningo-encephalopathy. It is these acute phases of intoxication, particularly encephalopathy, which are so often produced in children by an infection or other factor giving rise to an acidosis.

Colic in children is not often reported, but this may be due to its passing unrecognised and may account for the marked irritability sometimes found. Paralysis of the limbs is uncommon except in Queensland where, according to Nye, its frequent occurrence has earned for it the popular name of "the dangles." Unlike the adult, the paralyses in children are found more in the lower than in the upper limb, presumably because in children the legs are more fatigued than the arms. Pains and reflex changes may accompany the weakness.

Lockhart Gibson[20] has drawn attention to the effects of lead on the eye, and regards these conditions as common, though other writers consider them rare. Papillœdema and ocular palsy are found usually with encephalopathy, though they may occur alone. Optic atrophy sometimes results when these cases are left untreated, but the ocular palsies always recover.

Lead encephalopathy is the most serious of the acute manifestations of poisoning in children, and is common, having occurred in 45 of the 89 cases mentioned by McKhann. The symptoms caused by the acute cerebral œdema are those of a raised intracranial pressure with depression and excitation of the brain. There is headache, vomiting, papillœdema, and a bulging fontanelle with stupor or coma. There may be paralyses of the ocular or limb muscles, and the children are sometimes delirious or tremulous. Convulsions and twitching are common and have been noted to occur in groups. In many cases there are, in addition, signs of meningeal irritation such as neck rigidity and head retraction, and this may be reflected in the cerebro-spinal fluid by a pleocytosis. The fluid is always under increased pressure and the protein content is raised, but the rise in cell count is not constant. Fever which is often present is due in most cases to an accompanying infection.

The prognosis in encephalopathy is serious: of 20 cases recorded by Holt 11 died and only 1 escaped permanent cerebral damage. Mental deficiency, convulsions, blindness from optic atrophy, and cerebral palsies have all resulted from the ischæmia produced during lead encephalopathy by the acute cerebral œdema. Apart from such nervous sequelæ, little has been noted of the late effects of lead poisoning, but Nye[12] believes that in Queensland chronic interstitial nephritis in children is commonly due to lead poisoning earlier in life. Among 80 consecutive cases of chronic interstitial nephritis he found 14 patients who had been treated in childhood for lead poisoning. Another late effect he has noticed is renal dwarfism.[22] In chronic poisoning lead is not always found in the excreta, but if an injection of parathormone be given and several days supply examined a positive result is more likely. Recently Shipley has published a spectroscopic method of detecting minute amounts in the blood.[23]

RADIOGRAPHIC AND OTHER MEANS OF DIAGNOSIS

In 1930 Park, followed shortly afterwards by Vogt[24 25] and Caffey, described the radiographic changes produced by lead in the bones of children and young animals. These changes appear as a band of increased density at the diaphyseal end of the growing bone, most marked where the growth is greatest (Figs. II. and IV.). The outline of the bone is unchanged and there is no evidence of irregularity at the epiphyseal junction or of raising of the periosteum. The epiphyses are quite normal. The degree of opacity and the width of the dense band varies with the amount of lead absorbed and the length of time that the absorption has been taking place. As the bone grows, the band tends to become wider and less well defined. The density is due to the deposition of lead in the bone chiefly and also to the condensation of the traveculæ. If the absorption of lead ceases, an area of bone of normal density appears on the epiphyseal side of the "lead line" (Fig. III.). As the metal is deposited only in the growing bone the changes are not seen in adults.

Similar, but not identical, appearances are seen in scurvy, congenital syphilis,[26] Albers-Schönberg's disease ("marble bones"), and in poisoning by vitamin D and elementary phosphorus, and a few cases have been reported where other heavy metals such as strontium and bismuth have been the cause. The clinical features in these conditions are usually sufficiently distinct to avoid confusion.

In scurvy, the fact that the band of density is not wide and has a zone of rarefaction behind it should make the diagnosis clear, and the "ground-glass" appearance of the bones and, in some cases, the presence of subperiosteal hæmorrhages may be noted; in addition the deformity at the joint and the pain help to confirm the diagnosis.

In congenital syphilis the periosteum is raised in a large percentage of cases and there may be changes at the ends of the diaphyses ranging from slight irregularity to actual destruction. In this condition also there is a dense line at the end of the bone, but it is narrow and has an area of lessened density just behind it.

Albers-Schönberg's disease is rare and must be distinguished by the history and clinical methods; this also applies to poisoning by other metals. In some cases of Albers-Schönberg's disease there is widening of the end of the bone, best seen at the lower end of the femur, and the presence of this makes diagnosis more easy.

In healing rickets the dense band is not so clean-cut and not so even in width, and in most cases the "saucer-

shaped " deformity can still be traced for some time after the healing has taken place. Here again the history is of great importance and no difficulty is likely to arise.

There are three types of cases in which lead poisoning may be suspected. First may be mentioned cases of convulsions of obscure origin or cases of sterile meningitis. Rickets with convulsions and tuberculous meningitis have been most frequently mistaken for this type of case. Secondly, cases showing papillœdema, with or without ocular palsy, for which no cause can be found. And lastly anæmic children who suffer from colic, constipation, and irritability, or in whom signs of peripheral limb palsy are found.

In the diagnosis of a suspected case of poisoning a history of having ingested lead in some form is important and is usually obtained. A lead line, though uncommon, is pathognomonic of plumbism. Stippling of the red cells with a mild secondary anæmia is one of the most constant diagnostic points, but the stippling varies considerably from day to day so that repeated search may be necessary. Stippled cells occur in other conditions, but their numbers are always very small compared with those found in lead poisoning. Another useful aid to diagnosis is radiography; lead paint has been seen in the intestines by this means, showing as " fleck " shadows mixed with the intestinal contents, and the typical bone changes may be found. Lastly, the blood, urine, and fæces may be examined for lead, and although its presence cannot always be detected it is found in the majority of cases.

TREATMENT

The treatment of lead poisoning in children is mainly the treatment of lead encephalopathy. First, all sources of lead should be removed, and, as one attack of acute intoxication predisposes to others, the child should in future be guarded carefully against further risks of poisoning.

The immediate aim of treatment is the lowering of intracranial pressure to safe limits, and the first and most useful means employed is the withdrawal of cerebro-spinal fluid by lumbar puncture. The injection of hypertonic solutions, theoretically justified, seems to have proved disappointing. Despite the objection raised by Shelling to the use of magnesium salts, a 25 per cent. solution of magnesium sulphate has been injected intramuscularly up to a dose of 0·2 g. per kg., and this drug, in addition to its action as a hypertonic solution, acts as a nervous depressant by virtue of its magnesium ion, and would be of use in cases of convulsions. In animals the depressant action of magnesium can be abolished immediately by the injection of an equal concentration of calcium, an antidote which should make this a safe method of treatment. A 15 per cent. saline solution or a 25 per cent. solution of glucose in normal saline may be given intravenously in doses of about 50 c.cm. to a child of 5 years. Any of these solutions may be administered rectally and, if they are retained for over half an hour, they exert a similar though slower and less pronounced action. In cases where convulsions and delirium are prominent features, sedatives should be given in addition to the above treatment.

The next most important point in treatment is to aid the rapid deposition of lead in the bones, and to this end calcium is used and is best given by an intramuscular injection of 5 to 10 c.cm. of 10 per cent. calcium gluconate. Later calcium lactate may be given by the mouth and a diet rich in milk. Measures to prevent an acidosis include the giving of alkali and the avoidance of starvation. Recently Shipley has shown that, although the normal diet of an infant contains sufficient phosphorus for his everyday needs, when the calcium intake is suddenly increased it tends to upset the calcium-phosphorus balance and cause an increased loss of both. He has proved experimentally that the giving of phosphorus and vitamin D will prevent rats from being poisoned by doses of lead that killed others not so protected. The phosphorus and vitamin D both act by increasing the deposition of lead, as of calcium, and therefore on theoretical grounds should be given.

The removal of the source of poisoning, hygienic surroundings, and an adequate diet with added vitamin D and perhaps calcium and phosphorus are advisable.

Many attempts at de-leading patients have been made by such means as the giving of a low calcium diet, the production of an acidosis, and the use of potassium iodide or parathormone, but such attempts in children are contra-indicated because of the danger of precipitating one of the toxic episodes. It is not possible to rid the body of all lead, and as lead deposited in the bones is harmless it is best left there to be retained or to be excreted spontaneously.

A CASE-HISTORY

A boy, aged 2 years, was admitted to the London Hospital on Oct. 13th, 1933. He was said to have been well till the age of 8 months when he had an attack of broncho-pneumonia, followed a few months later by a second attack with measles. Since then he had had repeated attacks of bronchitis and sore-throat, sometimes complicated by diarrhœa and vomiting. As far as can be judged his mental condition was normal. In the last six months he had been pale and irritable and had been treated as a case of "nutritional anæmia." A blood count six months before admission showed 5,000,000 red blood-cells and 48 per cent. hæmoglobin (Dare, normal = 85 per cent.), and five months later, despite iron therapy, the red blood-cells and hæmoglobin had fallen to 4,000,000 and 40 per cent. respectively. He had always been underweight, but his condition had deteriorated further during the last few months. He had become more irritable and suffered from attacks of screaming thought to be due to colic.

Some 16 hours before being brought to hospital he is said to have fallen in a fit and he was still unconscious on admission. The mother had noticed that of late he had developed a habit of eating dirt and chewing at whatever he could lay his hands on. She brought to hospital a bag of " tin soldiers," many of whom had lost their limbs and their coats of paint and were tooth-marked.

On examination he was comatose with widely dilated, non-reacting pupils and absent deep reflexes. The temperature was 101° F. and a definite tonsillitis was present. The discs and fundi appeared healthy and no abnormality was discovered in any of the other systems or in the urine. There were no signs of rickets or tetany, nor was there a " blue line " present. After a lumbar puncture the child became semi-conscious and twitching movements, which sometimes became generalised convulsions, were noted frequently during the first day. The fluid was under increased pressure but was normal apart from an increase of the total protein content to 0·09 per cent. Sedatives were given, an intramuscular injection of 5 c.cm. of 10 per cent. calcium gluconate, and 8 oz. of 20 per cent. magnesium sulphate solution rectally, but little of this last was retained. None of these measures produced any striking change in the patient's condition.

After two days of restless delirium a further series of convulsions occurred during the third day and two further lumbar punctures were performed. The child's condition then gradually improved, but he appeared to be mentally deficient and would put anything within reach into his mouth. For the first two weeks there was a mild irregular fever, but later the general condition improved and he was discharged a month after admission looking somewhat pale but otherwise fairly well apart

from his appearance of mental deficiency. He was treated after the first few days with calcium lactate, grs. 5 three times a day, and care was taken to avoid producing an acidosis.

A blood count performed three days after admission showed 5,000,000 red cells, 40 per cent. hæmoglobin (Dare), and 19,800 white blood corpuscles, 57 per cent. of which were polymorphonuclear cells. An abnormal degree of punctate basophilia was seen in later films. The fragility of the red cells was normal. No lead was found in the urine or fæces. X ray examination of the long bones showed the areas of increased density at the ends of the diaphyses, sometimes called "lead lines" (Figs. II. and IV.).

Readmission.—Five months after discharge the child was readmitted for further investigation. In this interval he had gained no weight and remained pale, but there were no abnormal physical signs apart from enlarged septic tonsils. From his aspect and behaviour it was obvious that he was mentally deficient and still suffered from pica. He had been guarded from all possible sources of lead, and had been treated with grs. 5 doses of iron and ammonium citrate and 5 minims of Radiostoleum three times a day. There had been no convulsions or colic, and no paralysis or "blue line" had appeared. A blood count still showed a considerable degree of anæmia: red cells 3,400,000, hæmoglobin 46 per cent.; no punctate basophilia. Radiography of the long bones showed that the "lead lines" were now some distance from the ends of the bones and had widened as a result of growth at the bone ends (Fig. III.).

Three intramuscular injections of 5 units parathormone (Lilly) were given over a period of four days, and the fæces collected for a week which included this period. On analysis by a *modification of Fairhall's chromate* method large amounts of lead were found.

The child was last seen on June 1st, 1934, when little change was noted in his condition.

SUMMARY

(1) A case is reported demonstrating the value of the radiological changes at the ends of the long bones as a sign of lead poisoning in children. (2) Lead is a possible source of poisoning in the home, especially that found in paint. (3) Lead is stored in the bones and while it remains there is harmless. Only during absorption and excretion do toxic symptoms appear. (4) The possibility of lead poisoning should be considered in cases of convulsions of obscure origin, of papillœdema and ocular palsy without obvious cause, and in cases of anæmia with colic or peripheral limb palsy.

Since lead is commonly found in the home within the reach of children it is surprising that more cases have not come to light, and the possibility of such cases passing unnoticed has prompted us to record this case.

We are indebted to Dr. A. G. Maitland-Jones for his permission to publish this case, and to Dr. Donald Hunter for advice and interest, and to Dr. J. R. Marrack for his skill and patience in tracing the lead excreted.

FRACTURES OF THE NECK OF THE FEMUR

By Bryan McFarland, M.D., M.Chir. Orth. Liverp., F.R.C.S. Edin.

HON. ASSISTANT ORTHOPÆDIC SURGEON TO THE ROYAL SOUTHERN HOSPITAL AND THE ROYAL LIVERPOOL CHILDREN'S HOSPITAL

(WITH ILLUSTRATIONS ON PLATE)

In three years 24 cases have been treated. They fall into three main groups: old fractures and recent fractures either low or high in the neck.

(1) *Old fractures* with absorption of the neck and established non-union. (5 cases). It is usually impracticable to obtain union, and in these cases a modified Lorenz osteotomy was performed followed by immobilisation in plaster-of-Paris from six to eight weeks. In one case only a fair functional result was obtained, but in 4 the result was very good. Fig. I. shows radiograms of one of these. The patient, aged 49 years, weighed 12 st.; she walked within three months of the operation and now walks with equal shoes and has no limp. There is three-quarters of an inch shortening; two-thirds of normal abduction of the hip; rotation is about half of normal; flexion is three-quarters of normal. She has no pain and can walk two miles easily and balances firmly on the injured leg.

(2) *Recent fractures low in the neck.*—In this series there were 6 cases. As is usual in fractures high in the neck, bony union was obtained in the cases treated. Two patients were not fit to stand active treatment. Of these one walks with support, the other died of myocardial degeneration, fibrillation, and exophthalmic goitre, all of which existed before the fracture.

(3) *Recent fractures high in the neck* (subcapital fracture).—Of 13 cases 4 were not considered suitable for treatment. This decision was arrived at only after consultation with physicians and anæsthetists. In such cases it is necessary to forego the chance of union in order to keep the patients alive. This does not mean that they must be condemned to lie in bed indefinitely. After a few days they can be induced to walk in a bucket-top calliper. Of the 4 patients considered unfit, 3 are walking with supports; 1 died some months after the fracture on account of septic absorption from a wound of the other leg. In 2 of the 9 remaining high cases there was impaction, and contrary to what has usually been advised, these fractures were not disimpacted; because they were in a sufficiently good position and the patients were aged 59 and 50 respectively. No anæsthetic was given, plaster-of-Paris was firmly applied, and immobilisation was continued for two and a half to

shaped " deformity can still be traced for some time after the healing has taken place. Here again the history is of great importance and no difficulty is likely to arise.

There are three types of cases in which lead poisoning may be suspected. First may be mentioned cases of convulsions of obscure origin or cases of sterile meningitis. Rickets with convulsions and tuberculous meningitis have been most frequently mistaken for this type of case. Secondly, cases showing papillœdema, with or without ocular palsy, for which no cause can be found. And lastly anæmic children who suffer from colic, constipation, and irritability, or in whom signs of peripheral limb palsy are found.

In the diagnosis of a suspected case of poisoning a history of having ingested lead in some form is important and is usually obtained. A lead line, though uncommon, is pathognomonic of plumbism. Stippling of the red cells with a mild secondary anæmia is one of the most constant diagnostic points, but the stippling varies considerably from day to day so that repeated search may be necessary. Stippled cells occur in other conditions, but their numbers are always very small compared with those found in lead poisoning. Another useful aid to diagnosis is radiography; lead paint has been seen in the intestines by this means, showing as "fleck" shadows mixed with the intestinal contents, and the typical bone changes may be found. Lastly, the blood, urine, and fæces may be examined for lead, and although its presence cannot always be detected it is found in the majority of cases.

TREATMENT

The treatment of lead poisoning in children is mainly the treatment of lead encephalopathy. First, all sources of lead should be removed, and, as one attack of acute intoxication predisposes to others, the child should in future be guarded carefully against further risks of poisoning.

The immediate aim of treatment is the lowering of intracranial pressure to safe limits, and the first and most useful means employed is the withdrawal of cerebro-spinal fluid by lumbar puncture. The injection of hypertonic solutions, theoretically justified, seems to have proved disappointing. Despite the objection raised by Shelling to the use of magnesium salts, a 25 per cent. solution of magnesium sulphate has been injected intramuscularly up to a dose of 0·2 g. per kg., and this drug, in addition to its action as a hypertonic solution, acts as a nervous depressant by virtue of its magnesium ion, and would be of use in cases of convulsions. In animals the depressant action of magnesium can be abolished immediately by the injection of an equal concentration of calcium, an antidote which should make this a safe method of treatment. A 15 per cent. saline solution or a 25 per cent. solution of glucose in normal saline may be given intravenously in doses of about 50 c.cm. to a child of 5 years. Any of these solutions may be administered rectally and, if they are retained for over half an hour, they exert a similar though slower and less pronounced action. In cases where convulsions and delirium are prominent features, sedatives should be given in addition to the above treatment.

The next most important point in treatment is to aid the rapid deposition of lead in the bones, and to this end calcium is used and is best given by an intramuscular injection of 5 to 10 c.cm. of 10 per cent. calcium gluconate. Later calcium lactate may be given by the mouth and a diet rich in milk. Measures to prevent an acidosis include the giving of alkali and the avoidance of starvation. Recently Shipley has shown that, although the normal diet of an infant contains sufficient phosphorus for his everyday needs, when the calcium intake is suddenly increased it tends to upset the calcium-phosphorus balance and cause an increased loss of both. He has proved experimentally that the giving of phosphorus and vitamin D will prevent rats from being poisoned by doses of lead that killed others not so protected. The phosphorus and vitamin D both act by increasing the deposition of lead, as of calcium, and therefore on theoretical grounds should be given.

The removal of the source of poisoning, hygienic surroundings, and an adequate diet with added vitamin D and perhaps calcium and phosphorus are advisable.

Many attempts at de-leading patients have been made by such means as the giving of a low calcium diet, the production of an acidosis, and the use of potassium iodide or parathormone, but such attempts in children are contra-indicated because of the danger of precipitating one of the toxic episodes. It is not possible to rid the body of all lead, and as lead deposited in the bones is harmless it is best left there to be retained or to be excreted spontaneously.

A CASE-HISTORY

A boy, aged 2 years, was admitted to the London Hospital on Oct. 13th, 1933. He was said to have been well till the age of 8 months when he had an attack of broncho-pneumonia, followed a few months later by a second attack with measles. Since then he had had repeated attacks of bronchitis and sore-throat, sometimes complicated by diarrhœa and vomiting. As far as can be judged his mental condition was normal. In the last six months he had been pale and irritable and had been treated as a case of "nutritional anæmia." A blood count six months before admission showed 5,000,000 red blood-cells and 48 per cent. hæmoglobin (Dare, normal = 85 per cent.), and five months later, despite iron therapy, the red blood-cells and hæmoglobin had fallen to 4,000,000 and 40 per cent. respectively. He had always been underweight, but his condition had deteriorated further during the last few months. He had become more irritable and suffered from attacks of screaming thought to be due to colic.

Some 16 hours before being brought to hospital he is said to have fallen in a fit and he was still unconscious on admission. The mother had noticed that of late he had developed a habit of eating dirt and chewing at whatever he could lay his hands on. She brought to hospital a bag of "tin soldiers," many of whom had lost their limbs and their coats of paint and were tooth-marked.

On examination he was comatose with widely dilated, non-reacting pupils and absent deep reflexes. The temperature was 101° F. and a definite tonsillitis was present. The discs and fundi appeared healthy and no abnormality was discovered in any of the other systems or in the urine. There were no signs of rickets or tetany, nor was there a "blue line" present. After a lumbar puncture the child became semi-conscious and twitching movements, which sometimes became generalised convulsions, were noted frequently during the first day. The fluid was under increased pressure but was normal apart from an increase of the total protein content to 0·09 per cent. Sedatives were given, an intramuscular injection of 5 c.cm. of 10 per cent. calcium gluconate, and 8 oz. of 20 per cent. magnesium sulphate solution rectally, but little of this last was retained. None of these measures produced any striking change in the patient's condition.

After two days of restless delirium a further series of convulsions occurred during the third day and two further lumbar punctures were performed. The child's condition then gradually improved, but he appeared to be mentally deficient and would put anything within reach into his mouth. For the first two weeks there was a mild irregular fever, but later the general condition improved and he was discharged a month after admission looking somewhat pale but otherwise fairly well apart

from his appearance of mental deficiency. He was treated after the first few days with calcium lactate, grs. 5 three times a day, and care was taken to avoid producing an acidosis.

A blood count performed three days after admission showed 5,000,000 red cells, 40 per cent. hæmoglobin (Dare), and 19,800 white blood corpuscles, 57 per cent. of which were polymorphonuclear cells. An abnormal degree of punctate basophilia was seen in later films. The fragility of the red cells was normal. No lead was found in the urine or fæces. X ray examination of the long bones showed the areas of increased density at the ends of the diaphyses, sometimes called "lead lines" (Figs. II. and IV.).

Readmission.—Five months after discharge the child was readmitted for further investigation. In this interval he had gained no weight and remained pale, but there were no abnormal physical signs apart from enlarged septic tonsils. From his aspect and behaviour it was obvious that he was mentally deficient and still suffered from pica. He had been guarded from all possible sources of lead, and had been treated with grs. 5 doses of iron and ammonium citrate and 5 minims of Radiostoleum three times a day. There had been no convulsions or colic, and no paralysis or "blue line" had appeared. A blood count still showed a considerable degree of anæmia: red cells 3,400,000, hæmoglobin 46 per cent.; no punctate basophilia. Radiography of the long bones showed that the "lead lines" were now some distance from the ends of the bones and had widened as a result of growth at the bone ends (Fig. III.).

Three intramuscular injections of 5 units parathormone (Lilly) were given over a period of four days, and the fæces collected for a week which included this period. On analysis by a modification of Fairhall's chromate method large amounts of lead were found.

The child was last seen on June 1st, 1934, when little change was noted in his condition.

SUMMARY

(1) A case is reported demonstrating the value of the radiological changes at the ends of the long bones as a sign of lead poisoning in children. (2) Lead is a possible source of poisoning in the home, especially that found in paint. (3) Lead is stored in the bones and while it remains there is harmless. Only during absorption and excretion do toxic symptoms appear. (4) The possibility of lead poisoning should be considered in cases of convulsions of obscure origin, of papillœdema and ocular palsy without obvious cause, and in cases of anæmia with colic or peripheral limb palsy.

Since lead is commonly found in the home within the reach of children it is surprising that more cases have not come to light, and the possibility of such cases passing unnoticed has prompted us to record this case.

We are indebted to Dr. A. G. Maitland-Jones for his permission to publish this case, and to Dr. Donald Hunter for advice and interest, and to Dr. J. R. Marrack for his skill and patience in tracing the lead excreted.

The patient, aged 49 years, weighed 12 st.; she walked within three months of the operation and now walks with equal shoes and has no limp. There is three-quarters of an inch shortening; two-thirds of normal abduction of the hip; rotation is about half of normal; flexion is three-quarters of normal. She has no pain and can walk two miles easily and balances firmly on the injured leg.

(2) *Recent fractures low in the neck.*—In this series there were 6 cases. As is usual in fractures high in the neck, bony union was obtained in the cases treated. Two patients were not fit to stand active treatment. Of these one walks with support, the other died of myocardial degeneration, fibrillation, and exophthalmic goitre, all of which existed before the fracture.

(3) *Recent fractures high in the neck* (subcapital fracture).—Of 13 cases 4 were not considered suitable for treatment. This decision was arrived at only after consultation with physicians and anæsthetists. In such cases it is necessary to forego the chance of union in order to keep the patients alive. This does not mean that they must be condemned to lie in bed indefinitely. After a few days they can be induced to walk in a bucket-top calliper. Of the 4 patients considered unfit, 3 are walking with supports; 1 died some months after the fracture on account of septic absorption from a wound of the other leg. In 2 of the 9 remaining high cases there was impaction, and contrary to what has usually been advised, these fractures were not disimpacted; because they were in a sufficiently good position and the patients were aged 59 and 50 respectively. No anæsthetic was given, plaster-of-Paris was firmly applied, and immobilisation was continued for two and a half to

three months. Bony union occurred satisfactorily (Fig. II.). Both patients are able to walk comparatively long distances, and movements are more than three-quarters of normal. It is perhaps of some interest that both these patients walked into the out-patient department. It is exactly this type of fracture which is missed and treated as rheumatism or as sciatica until non-union has commenced.

The remaining 7 fractures were subcapital and non-impacted. It is in these cases that the greatest difficulty lies. It is probable that bony union in any fracture depends upon four factors: apposition, immobilisation, blood-supply, and some chemical or hormonic influence. When the blood-supply of a fractured part is poor, immobilisation must be more accurate and more prolonged. It is therefore obvious that in subcapital fractures of the neck of the femur accurate apposition and prolonged immobilisation are of supreme importance. At the same time it is the duty of the surgeon to obtain his results in the simplest possible manner, and to remember that although union in a good position is desirable, the patient's life must not be unnecessarily endangered. The following method, which is a modification of Royal Whitman's method, will be found simple and effective.

Under general anæsthesia reduction is effected by flexing the knee, flexing the hip at a right angle, and putting the leg in slight adduction. Pressure is then applied in a forwards and downwards direction against the upper and back part of the trochanter. The fractures will be felt to crepitate and the femur will be felt to move downwards and inwards in relation to the pelvis (and therefore to the head of the femur). The leg is then extended, abducted, and internally rotated. If reduction has been effected the length will be equal to that of the other leg and internal rotation will be easy and the leg will remain internally rotated. A plaster-of-Paris spica is applied with the knee in slight flexion. The pelvis must be firmly gripped and the foot must be included. The degree of success probably depends upon the fixation which any individual operator can obtain with his plaster. Recumbency is enforced for two and a half months; the patient should then be encouraged to walk in the plaster, the foot having been released. If this is found impossible a walking calliper can be applied at the end of three and a half months. Since the leg is abducted, the other foot should be raised slightly when walking is started.

The following details give an idea of the duration of recumbency and the results of subcapital fractures.

CASE 1.—Aged 23 years. *Walking three months after* the fracture. Final result: no pain; bony union; no deformity; can walk any distance; rides a bicycle.

CASE 2.—Aged 67 years. Walking at the end of two and a half months. Bony union; no deformity; no pain. Movement three-quarters of normal. Suffers from extensive osteo-arthritis in both knees and in the other hip. Has attended Harrogate for years for rheumatism. Now can walk any distance in reason. Dances and plays golf.

CASE 3.—Aged 53 years. *Walking in two and a half* months. Bony union when examined one year after accident.

CASE 4 (Fig. III.).—Aged 58 years. Walking in three and a half months. Result: bony union; no shortening; wears high-heeled shoes; has slight pain. Can walk a mile and can stand on injured leg.

CASE 5 (Fig. IV.).—Aged 43 years. Walking in five months. A little pain. Has old-standing thrombosis. Can walk a mile easily. Can stand on injured leg; can go upstairs well; has no limp. Bony union when seen one year after accident.

CASE 6.—Aged 59 years. Walking in five months; timid; bony union; no deformity; no pain; no limp. Can walk easily for two or three miles. Did hill-climbing fifteen months after the accident. Can stand on injured leg.

CASE 7.—Aged 73 years. Walking six months after accident. Half normal movements of hip; half an inch of shortening; no pain; can get about freely. Bony union one year after accident.

In all the 13 recent fractures treated actively bony union took place in good position and with good function. There were no complications such as pneumonia or pressure sores.

RADIOGRAPHIC EVIDENCE OF LIVE BIRTH

BY MIRON HAJKIS, M.B. Oslo, L.M. Rotunda

(WITH ILLUSTRATIONS ON PLATE)

Sydney Smith[1] states that if a child has not breathed the stomach and intestines contain no air. My own findings agree with this statement. Using X rays I have been unable to demonstrate air in the stomach or intestine of stillborn children, even when a large quantity of meconium has been passed (Fig. I.). My observations also support Smith's view that the presence of air in the stomach and bowel is a useful confirmatory sign of respiration, especially in "cases where the lung has not been expanded either from weakness of the respiratory movement or from blocking of the respiratory passages. In such cases," he says, "air may still be swallowed, and from its presence in the stomach and bowel afford evidence of attempted respiration."

Breslau (quoted by Buchanan[2]) states that the presence of gas in the stomach and intestine is contemporaneous with respiration and independent of the ingestion of food. I have found X ray evidence of air in stomach and bowel in all of six infants with extensive atelectasis which were born alive and survived for periods from five minutes to eight hours. Indeed, in the new-born live child, which has not been fed by mouth, the stomach and intestines are often outlined radiographically as if they were filled with an opaque meal (Figs. II., III., and V.). In all the cases I made a post-mortem investigation immediately after radiography, and the findings corresponded with the X ray pictures in regard to the extent of atelectasis and presence of air in stomach and intestines as tested by the routine forensic methods. The radiographic examinations showed that atelectasis was most pronounced in the bases of the lungs, more in the left than the right lung, and that aeration was established in the margins (Taylor) or the right apex (Glaister). It may be suggested that in the cases illustrated the air in the bowel came from insufflation, but this can be disproved by referring to other cases in which this procedure was not resorted to (Figs. III. and V.). Further, I made experiments on stillborn infants immediately after birth to discover whether air can be made to enter the bowel by mouth-to-mouth insufflation, and I found that even by gross exaggeration of the clinical method I could inflate only the stomach. I agree, therefore, with Buchanan that air in the duodenum is strong evidence of live birth. Even when radiography was delayed until 24 or 48 hours after insufflation it was noted that air had not entered the duodenum (Fig. IV.) though the stomach showed slightly more distension. (The bodies had been kept in a mortuary at about 65° F.) Nor was I able artificially to inflate the lungs in these stillborn infants.

The penetration of air to the stomach and intestines is due to the vital functions of swallowing and peristalsis, and its presence in the intestinal tract is very striking in the X ray pictures in contrast to the imperfect aeration of the lungs in cases of extensive atelectasis. Of the three essentials in the establishment of life—namely, the action of the heart, respiration, and deglutition and peristalsis—full respiration is the most difficult to establish fully. Respiration appears to be impossible without deglutition and peristalsis, and in the infant, as in the adult, asphyxia exaggerates peristalsis and so encourages the movement of any air that enters the intestinal tract.

In the course of my investigations I came across one embarrassing case (Fig. V.).

A radiogram of this child, said to be born dead, shows poor aeration of the lungs, the highest point of the diaphragm being in the seventh interspace. There is air in the stomach and intestine. The presentation was by the breech, and during delivery of the head by the Mauriceau-Smellie-Veit manœuvre the accoucheur felt the attempts at suckling with his finger; there was no crying. The explanation of this contrary finding is that the child was alive when the face was on the perineum, but did not survive the completion of the delivery. The body being born the respiratory movements could be performed. Needless to say such a case might present a problem in medico-legal practice. At autopsy no other cause of death could be discerned—certainly not intracranial hæmorrhage. The hydrostatic test demonstrated flotation of all parts of the lungs.

In this connexion I would like to mention a paper by Dennen,[3] and only offer my support for his opinion that radiography should be a routine in the diagnosis of morbid conditions of the newly born and especially of cyanosis. In Dennen's case X rays showed in a six-hour-old child almost complete atelectasis of the left lung, and only partial expansion of the right lung. Four days later there was normal expansion of both lungs and the child survived, whereas in my cases the atelectasis was much more extensive and resulted in death. In such cases X rays would be of value not only in diagnosis and appropriate treatment as Dennen insists, but also in prognosis by indicating the extent of the atelectasis.

As in my cases I could discern no cause of death apart from extensive atelectasis—and especially not intracranial hæmorrhage—I was forced to the conclusion that the persistent atelectasis, to use Taylor's expression,[4] was the cause of death. Glaister [5] states amongst the causes of death in the newly born atelectasis is probably the most common of the lung conditions.

From the medico-legal standpoint X rays provide invaluable means of obtaining information about the presence of air in stomach and intestines. My observations show that air is to be found there only when the child has breathed, and in my opinion radiography of the lungs and intestinal tract provides the best proof of live birth. The possibility that gas may be produced by putrefaction in lungs or intestine must be borne in mind; but the bubbles arising in this way would give an appearance different from that of air-filled alveoli or bowel which has been aerated by peristalsis.

Part of this work was done at the Rotunda Hospital, Dublin, by kind permission of Dr. Bethel Solomons, then the Master.

RENAL DWARFISM

ASSOCIATED WITH CALCIFICATION OF ARTERIES AND SKIN

By Robert Platt, M.D. Sheff., M.R.C.P. Lond.
HON. ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY, SHEFFIELD; AND

Trevor K. Owen, M.Sc., M.B. Sheff., M.R.C.P. Lond.
ASSISTANT PATHOLOGIST, LONDON COUNTY COUNCIL GROUP LABORATORY, LEWISHAM HOSPITAL

(WITH ILLUSTRATION ON PLATE)

Metastatic calcification occurring in chronic nephritis in adults, although extremely rare, has been known since Virchow first described five cases in 1855. But in chronic nephritis of childhood (renal dwarfism) an extensive search has revealed only two cases showing calcification of the arteries—viz., that of Smyth and Goldman[1]—in which five remarkably enlarged parathyroids were discovered at autopsy, and the case recorded by Karelitz and Kolomoyzeff,[2] in which large doses of viosterol had been given before the calcification was noted. The following case in which no vitamin D had been given and no enlarged parathyroids were found therefore seems worthy of record.

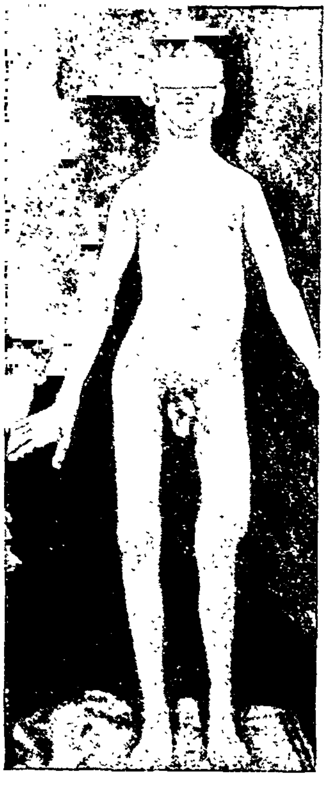

FIG. I.—Photograph of the patient.

A. B., aged 18, was sent to the skin department of the Sheffield Royal Infirmary on May 15th, 1933, on account of dry thickened skin with pigmented areas in axillæ and groins. As it was obvious that he was profoundly anæmic and extremely ill, he was transferred to the medical department. We there obtained a history that he had not been well and strong for many years, that he was always very thirsty, and passed a great deal of urine both by day and night. The thirst and polyuria had existed since he was a small child, and definitely before he had scarlet fever at the age of 6. There was no history of nephritis accompanying the latter illness. He appeared somewhat drowsy and mentally slow, but had reached Standard VII. when he left school at the age of 14. When 15 years old he began to work and developed knock-knee, for which an osteotomy was performed on the left leg. His appetite had been poor for many months, but he complained of no headache or vomiting. His height was 5 ft., his weight 4 st. 5 lb., and the accompanying photograph (Fig. I.) shows his undersized, rickety, and emaciated condition. His skin was dry, sallow, and pigmented, and in the areas noted was raised up into hard plaques. His lips were extremely pale and he had all the appearances of chronic nephritis in childhood. The heart was obviously enlarged, and the blood pressure was 155/100. There was no retinitis. The urine was very pale, specific gravity 1010 to 1012, albumin

1 to 2 g. per litre. Blood tests on admission to hospital on May 19th gave the following results :—

Hæmoglobin	30 per cent.
Red cells	1,560,000 per c.mm.
Colour-index	0·98
White cells	17,900 per c.mm.
Differential count	Normal.
Sedimentation-rate ..	Much increased
Wassermann reaction ..	Negative.
Non-protein-nitrogen ..	333 mg. per 100 c.cm.
Urea nitrogen	205 „ „ „
Cholesterol	179 „ „ „
Blood phosphorus	15·1 „ „ „
Serum calcium	6·7 „ „ „
Indican	Very strongly positive.

Radiogram of the spine, including the sacrum, showed remarkable erosion of bone. The limbs showed rickety changes with erosion, marked calcification of arteries (*Fig. II. on Plate*) and calcification of pigmented areas of the skin.

In hospital he became rather more drowsy and developed extreme dyspnœa. The non-protein-nitrogen rose to 400 mg. per 100 c.cm., and he died in coma without convulsions on May 28th.

At the post-mortem the kidneys (Fig. III.) were found to be extremely small, each weighing ¾ oz., and were of a pale mottled colour. Microscopically, the most striking changes were a great degree of interstitial fibrosis, and dilatation of the tubules. Aggregations of lymphocytes were present. The glomeruli were few in number and showed varying degrees of endothelial proliferation and fibrosis. The vessels showed hypertrophy, chiefly of the media. There was no hypertrophy of the bladder or ureters. The heart weighed 9½ oz., and there was some hypertrophy of the left ventricle. The lungs were very œdematous, with a small left-sided pleural effusion. Calcification of the medium-sized and small arteries was found as shown in the radiogram, but the aorta was quite free. The spleen contained three old infarcts, and calcified vessels could be felt in the pulp. The other organs were normal. There was no enlargement of the parathyroids. Sections of the skin showed calcium deposits immediately beneath the epidermis.

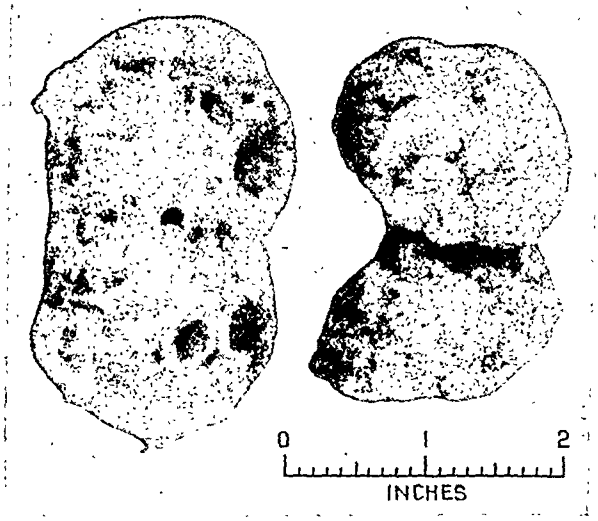

FIG III—Photograph showing extremely contracted kidney.

BILATERAL SPONTANEOUS PNEUMOTHORAX

WITH REPORT OF A CASE

By SINCLAIR R. WILSON, M.D. Glasg., D.P.H.
CONSULTANT TUBERCULOSIS OFFICER TO THE WEST RIDING COUNTY COUNCIL

(WITH ILLUSTRATIONS ON PLATE)

A CASE of bilateral spontaneous pneumothorax is seen sufficiently rarely to merit description, and when it does arise it stimulates an interest in a subject which, because of its rarity, receives but scant consideration in the ordinary routine of a tuberculosis service. Spontaneous pneumothorax (unilateral) is fairly frequent but the bilateral form has not been described more than 50 times.

Bilateral cases may be divided into two types: (1) successive and (2) simultaneous. The first variety shows the pneumothorax now on one side and now on the other, but never together on both sides. Naturally the second variety, in which bilateral pneumothorax occurs simultaneously, is more likely to end fatally.

The ætiology of bilateral spontaneous pneumothorax is not definitely agreed upon. Among the causes may be mentioned: (*a*) rupture of tubercles on the surface of the lungs; (*b*) rupture of emphysematous bullæ; (*c*) an inherent fragility of the surface of the lungs; (*d*) fistulisation through the mediastinum between both pleural cavities; (*e*) a possible anatomical deformity in the development of the lungs, in which the human development has simulated that of some of the lower animals, where the pleural cavities are connected; and (*f*) some violent exertion—e.g., coughing, sneezing, physical strain, and, rarely, trauma.

According to McMahon,[1] who reviews what has been written on the subject, 58 per cent. of cases of bilateral spontaneous pneumothorax are associated with pulmonary tuberculosis. These are usually fatal. Another 16 per cent. are associated with emphysema. These also usually end fatally. A few cases are associated with secondary growths of carcinoma, and naturally are usually fatal. A few cases are associated with trauma, and here there is some tendency towards recovery.

McMahon's case was not due to pulmonary tuberculosis, either clinically or radiologically. Meyer[2-4] describes two cases associated with pulmonary tuberculosis, and one unusual case which followed coitus and ended fatally after the fourth occurrence. Fine[5] reports one in which the condition was possibly due to long-continued colds and asthmatic attacks, was definitely non-tuberculous, but ended fatally. Lamont[6] described a case which was non-tuberculous but occurred after very extreme exertion and resulted in recovery. Bedford and Joules[7] report one in which the spontaneous bilateral pneumothorax developed apparently without exertion, and came on during the night; there was no evidence of pulmonary tuberculosis, and the patient recovered. Bourne[8] records a case in an infant which died of miliary tuberculosis, Emerson[9] one due to asthma, and Mills[10] one arising after injury. Miller[11] describes bilateral spontaneous pneumothorax due to chronic tuberculosis with recovery.

CASE RECORD

The patient was referred to me by Dr. S. H. Waddy of Huddersfield, to whom I am indebted for a résumé of her previous history.

In May, 1923, she suffered from influenza, which was followed by anæmia and scanty menstruation. This condition steadily improved. In April, 1924, there was a period of tachycardia, cardiac irregularity, and dyspnœa, which was the result of a very severe cold. During the whole of 1924 the patient had periods of general malaise and cardiac irregularity. In October, 1927, she complained of palpitation, dyspepsia, a sinking feeling after food, and a dragging pain in the left lower abdomen. There was at this time dysmenorrhœa, but no physical signs in uterus or abdomen generally. During 1928 and 1929 there were occasional attacks of sickness and gastric discomfort, and sometimes a sensation of a "hollow feeling." In October, 1930, she complained of pain in the right shoulder, which improved very quickly. This was diagnosed as a rheumatic pain. In November, 1930, the heart action was still irregular, and the patient brought up a little blood on coughing. The sensations she had were of a dragging nature from the throat down to the abdomen, and were apparently nervous. In February, 1931, the patient brought up slightly pink phlegm, a specimen of which was found to be negative for tubercle bacilli. In January, 1932, there was pain in the left arm and shoulder, the cause being either rheumatism or possibly referred pain due to her cardiac irregularity. During this month she had attacks of pain in the chest, rather general, and sometimes located on the right side, the latter suggesting a tubercular pleurisy. In February, 1932, she had slight hæmoptysis and tachycardia.

The physical examination of the patient, whom I saw shortly after the last hæmoptysis, revealed remarkably few physical signs of disease in the chest. I suspected the right lung, which had fairly widespread granular breath sounds, but no definite crepitations. There was slight dullness to percussion over the right lung, but in the left lung the signs were practically normal. The heart sounds were also normal. The patient's general condition was very good, and she was well nourished; the sputum test was negative, and in consideration of the history of cardiac irregularity one might have been tempted to rule out pulmonary tuberculosis entirely. Radiological examination was definitely necessary and the first report I was able to make, on April 22nd, was as follows (Fig. I.):—*Right:* deep-seated disease, which gradually becomes thinner towards the lung surface; a spontaneous pneumothorax is present, shown along the whole of the outer surface of the lung, regular in outline; no fluid present in pleural space. *Left:* certain amount of haziness of lung tissue, with some peribronchial thickening; fine nodular disease present. Heart: slightly to the left.

In the light of the above report the re-perusal of the patient's history made me suspect that spontaneous pneumothorax had probably been taking place in this patient's chest off and on since October, 1930, when she complained of pain in the right shoulder. I did not suspect the possibility of the case being a bilateral one, and still considered that the pain she had felt in her left arm in January, 1932, was a referred pain due to her heart action. Having formed the opinion that the spontaneous pneumothorax on the right side was probably due to a valvular opening in the visceral pleura of the right lung, I took the pressure in the pleural space a few days after radiological examination and found that it was −7 −4. I inferred from this, and from the physical signs, that the lung was expanding again. I therefore repeated the radioscopy on May 3rd and was amazed to find that a complete spontaneous pneumothorax now existed on the left side. The spontaneous pneumothorax on the right side had disappeared (Fig. II.). At this point I may add that the patient complained of slight pain in her left shoulder, a certain degree of dyspnœa, and some palpitation, but this did not prevent her travelling several miles to attend the radiological centre

I now concluded that I had a case of spontaneous bilateral pneumothorax of the successive type, but I was not certain when she might become of the simultaneous type. I therefore recommended absolute rest in a sanatorium for at least four months, in the hope that some pleural adhesion might develop to anchor these mobile lungs. On June 15th the left lung had almost fully re-expanded though there was a small pneumothorax at the apex; but on August 30th the left pneumothorax had again increased (Fig. III.). At the end of four months in the sanatorium she was considered by the medical officer in charge to be well enough to be sent home, and certainly her condition generally was very satisfactory. The day after her return home, however, she developed acute dyspnœa and very great collapse, and shortly afterwards died, evidently having succumbed to simultaneous bilateral pneumothorax.

COMMENT

In this case of bilateral spontaneous pneumothorax due to pulmonary tuberculosis a fairly long period of absolute rest was evidently insufficient to stabilise the lungs in a natural way. One may, therefore, infer that the natural tendency for the production of pleural adhesions was either absent or very slight.

The almost inevitable development of simultaneous bilateral pneumothorax, especially in a case associated with pulmonary tuberculosis, suggests that an endeavour should be made to produce pleural adhesions artificially. The ideal aimed at in the performance of artificial pneumothorax—i.e., the non-development of pleural adhesions—is reversed when the case is one of spontaneous pneumothorax. Any interference directed to the production of pleural adhesions is not indicated, however, unless the patient's general condition, as in the present case, is satisfactory, and the radiological diagnosis warrants it. The adhesions might be produced by some form of cauterisation, or, possibly, by the injection of some irritant fluid into the pleural cavity.

LYMPHOGRANULOMA INGUINALE

ACQUIRED IN ENGLAND

By K. Vigors Earle, M.B. Camb. and Lond.
RESIDENT MEDICAL OFFICER, LONDON LOCK HOSPITAL

Reports of proved cases of lymphogranuloma inguinale acquired in this country are still rare. Cases purporting to be such have been recorded by McDonagh, by Hanschell, and by Gibson (1931); these were diagnosed on clinical grounds. Todd described a case which he claimed to be one of lymphogranuloma inguinale on the strength of the histological appearances of the excised glands.

The first case in which the diagnosis was confirmed by laboratory findings was described by Stannus and Findlay in February, 1933. Here Frei's test was negative, but as the patient was syphilitic this failure could be ascribed to "anergy." ("Anergy," described by Frei, is the condition where no response to antigen injection occurs, and may occur during the pre-menstrual period, in early syphilis, in tuberculosis, in septicæmia, and during prolonged pyrexia.) Later in 1933 Anwyl-Davies, King, and Findlay reported a case of lymphogranuloma inguinale, acquired in Limehouse, the pus from which produced characteristic changes on animal inoculation. Frei's test was not performed.

CASE-HISTORY

The present case is that of an unmarried man aged 24, a Cypriot, by occupation a scullion. Had lived in England for the past four years, without leaving the country.

MEDICAL SOCIETIES

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION

At a meeting of this association held at B.M.A. House on June 26th, with Prof. Mary Lucas Keene in the chair, Dr. Letitia Fairfield spoke on

Eugenic Sterilisation of the Unfit

Dr. Fairfield based her observations on the recent report of the Departmental Committee on Sterilisation (the Brock Report[1]). She pointed out that the wide popular interest in sterilisation had grown out of two main factors. First, the increase in biological knowledge of the hereditary factor in mental and physical disease; and, secondly, the sociological outlook which attributed numerous evils of society to mental and physical "unfitness." The appointment of the committee was inevitable, for it had become fashionable to regard sterilisation as a panacea, and in the case of mental deficiency, for example, the over-emphasis on sterilisation had been allowed to swamp every other aspect of a many-sided problem. It was only fair to state that the efforts of many prominent eugenists and the findings of the Departmental Committee's Report were directed towards correcting these exaggerated claims. Dr. Fairfield then reviewed the findings of the report. She considered that the legal obstacles in the way of the eugenic sterilisation of persons of normal mentality had been somewhat exaggerated. As a matter of fact no one who was able to pay for such an operation at the present day had the least difficulty in getting it done and probably more hospitals were performing such operations than was supposed. No case of a surgeon suffering any penalty for doing a eugenic sterilisation was on record and it was impossible to imagine such a case being brought into court, provided that genuine grounds existed for believing that diseased offspring might be procreated. It was recognised, however, that the sterilisation of mental defectives is undoubtedly illegal.

In examining the present knowledge of the causation of mental defect the committee had evidently, Dr. Fairfield said, found itself on highly contentious ground. All their witnesses agreed on the important part played by "heredity" but they were not at one on the exact meaning of the term. Some would include in the family tree any deviation from the normal, including epilepsy, instability, delinquency, insanity, while others would confine the term to the transmission of a single defect such as certifiable mental deficiency. Naturally the percentage of "hereditary" cases differed according to the view taken, the variation extending from 5 per cent. to 80 per cent. The report had recorded some interesting researches into the mentality of the offspring of defectives, who showed an unexpectedly high rate of mental deficiency—i.e., nearly one-third of surviving children. She pointed out, however, that the figures were overweighted, as defective offspring were likely to call the attention of the authorities to defective parents. The report further blackened the picture by bracketing the "subnormal" and defective children, although the former might be little different from the general population. While assessing the part played by environment in causing mental abnormality many witnesses stressed the point that this factor acts in combination with defects of heredity, the thesis being: "Environmental factors may accentuate inherited weakness." The evidence also brought out a point which is still often overlooked—i.e., that mental deficiency is so devious in its manifestations that it cannot conceivably be a single unit transmissible in Mendelian lines, though certain subvarieties may be.

The final recommendations of the committee condemned compulsory sterilisation as unjustifiable in the present state of knowledge of genetics and likely to arouse public hostility. It was not clear, however, whether it would be possible to keep voluntary sterilisation really voluntary. It is difficult to imagine the precautions which would prevent enthusiastic committees from using the social services (such as outdoor relief), or the bait of discharge from an institution as an inducement to sterilisation. This was avowedly happening in other countries where sterilisation measures were on the statute book. As regards high-grade mental defectives, the committee evidently considered it an easy matter for a doctor to decide whether they were or were not mentally competent to give a valid consent to the operation, but no standards were laid down and Dr. Fairfield considered that in practice the point would be a very difficult one to determine. As regards mentally normal persons it seemed to have been overlooked that any attempt to regulate voluntary eugenic sterilisation would seriously restrict the freedom of action now enjoyed by the "well-to-do"—i.e., by all who could afford to pay for an operation. In future they would have to submit to an elaborate process beginning with two medical certificates, and involving reference to the Ministry of Health and possibly to the Board of Control or a special advisory committee of experts. Notoriously in the sight of a ministry a thousand years was but as a day, and the loving couple who longed to be united could hardly be expected to await inevitable official delays. It seemed probable that the regulation of voluntary sterilisation was doomed to failure. In view of the small proportion of institution cases who would be suitable for sterilisation, and the grave risks involved by any form of legislation on the subject, it seemed doubtful whether the recommendations of the report should receive general support.

Dr. C. P. Blacker (general secretary of the Eugenics Society) said he found himself in entire agreement with most of the points which Dr. Fairfield had made. The propaganda in favour of legalising eugenic sterilisation would, he said, do more harm than good if it were seized upon by local authorities as a justification for inertia or if it were interpreted by the general public as a measure likely to save the pocket of the ratepayers. Much confusion also centred around the meaning of the word "heredity." According to the report of the committee on mental deficiency appointed by the British Medical Association, the term "heredity" implied "that in the ancestry of any given case of mental deficiency there has existed a morbid condition of bodily and/or mental development, which may have taken the form either of mental deficiency or of some neuropathic condition, or of some other defect due to damage inflicted to one or other of the germ cells before fertilisation." According to this sweeping definition we would be justified in regarding as hereditary a given case of mental defectiveness if it were known that there had occurred in the ancestry of that defective a case of cleft palate in the time of William the Conqueror. Careful scrutiny of recent American and continental investigations into the heredity of mental deficiency pointed to the conclusion that the more carefully the pedigree was investigated the greater was the importance attributed to heredity as a causal factor and the larger was found to be the percentage of parents of high-grade defectives who were themselves on the borderline between subnormality and certifiable defectiveness. At the same time, it should be remembered that, though discussions on sterilisation continued to focus themselves upon mental deficiency, the recommendations of the Brock Report extended far beyond this sphere. The eugenic benefits, in fact, of legalising the voluntary sterilisation of mental defectives would probably turn out to be small as compared with the results of legalising it for persons who had recovered from mental disorder and for persons who exhibited or carried mental or physical disease or defect. The results, said Dr. Blacker, of the uncertainty in regard to the present state of the law regarding the sterilisation of persons who are compos mentis had at present the effect of discriminating against the poor. The legal risk, admittedly small, was willingly taken by surgeons who operated, in a private capacity, upon paying patients; the same surgeon, however, before operating upon a hospital patient usually found it necessary to obtain the consent of the superintendent of the hospital. This consent was often withheld, partly for fear of alienating Roman Catholic subscribers to the hospital and partly because, in view of the already long waiting-list, many hospitals hesitated to incur the smallest legal risk. Such discrimination between rich and poor was unfair, and it constituted a good argument for regularising the position for people of all classes by Act of Parliament. In the matter of safeguards, said Dr. Blacker, a course had to be steered between two opposing camps of critics, and, in his opinion, the recommendations of the Brock Committee constituted a happy via media. Some safeguards, he thought, were necessary. It was to be remembered that vasectomy was a simple operation, capable of being performed under a local anæsthetic; it took but a few minutes and necessitated at most a day's absence from work, yet it produced irreparable and irreversible effects. Every new law was exposed to certain criticisms and objections. Dr. Blacker was far from denying that a voluntary sterilisation law along the lines of the recommendations of the Brock Committee was exempt from these, but in deciding whether to oppose or to support it, the question we had to ask ourselves was: on balance did the advantages outweigh the disadvantages, and he believed that in this instance the answer was yes.

REVIEWS AND NOTICES OF BOOKS

Elements of Experimental Embryology

By JULIAN S. HUXLEY, M.A., Hon. Lecturer in Experimental Zoology at King's College; and G. R. DE BEER, M.A., D.Sc., Fellow of Merton College and Jenkinson Lecturer in Embryology, Oxford. London: Cambridge University Press. 1934. Pp. 514. 25s.

THIS member of the Cambridge Comparative Physiology series is an excellent book, in which the authors have set themselves to give a connected account of "prefunctional" development in the light of experimental results. The field of research here is enormous, and we imagine that, among the facts presented and the provisional principles based upon them, there will be something new for everybody, and much that is unknown to many. The authors, faced with the mass of material, were compelled to put limits to their activities, and this book is essentially concerned with the biological problem of differentiation. Epigenesis, of course, describes the process, but something of preformation (but not in the old sense) is demanded by the fact at least of specific development. Gradients are brought in to account for the determination of the embryo from an undifferentiated egg. We confess that we have never been able to convince ourselves that the axial and other gradients of C. M. Child possess a value beyond that of descriptive terms, but there can be no objection to their use in a formal provisional theory to provide for the possibility of the change. The consideration of polarity, symmetry and asymmetry, cleavage, and *differentiation* is full and satisfactory. A long and detailed account of gradients and gradient fields is followed by a very interesting chapter on the differentiation of the amphibian nervous system, and this by one on hereditary factors and differentiation. Two more chapters and an appendix complete the text, and there is a good bibliography.

The authors disclaim categorically any desire to enter on philosophical discussions, and are evidently of opinion that physics and chemistry hold the secrets of biology between them. We may not view the organism in the same way, but that does not keep us from admiring this work. The task of presenting and classifying a heterogeneous mass of facts, and of establishing the various components of development, has been carried out in a masterly way. With the exception of Morgan's work on experimental embryology we do not know of any book in the English language in which the vast amount of fact and detail has been presented to the reader in such reasoned order and sequence. The volume ought to be within reach of every worker in biology.

Diabetes Mellitus

Diagnosis and Treatment. Fifth edition. By O. LEYTON, M.D., D.Sc., F.R.C.P., Physician to the London Hospital. London: Adlard and Son, Ltd. 1934. Pp. 144. 6s. 6*d*.

THE fifth edition of this book incorporates a good deal of new work. Nearly a quarter of the space is devoted to the diagnosis of diabetes mellitus. In most cases this is easy, but it may be very difficult. Dr. Leyton describes five methods of determining it: (1) sugar-tolerance test; (2) progressive diet test; (3) effect of pancreatic rest; (4) intravenous injections of glucose; (5) effect of toxins on pancreatic efficiency. The sugar-tolerance test is the one most used, and it is, as a rule, easy to interpret. It may give doubtful or even misleading results, and Dr. Leyton explains how these can be avoided. The progressive diet test is very valuable as it will often differentiate between doubtful sugar-tolerance curves. The observations can be completed in ten days at the most by Dr. Leyton's method; four days is considered sufficient by many workers. In some cases it is advisable to treat the patient with a diet which will rest the pancreas, and to repeat the sugar-tolerance test and progressive diet test at intervals of three to six months. The other two methods mentioned—

i.e., the effect of toxins on pancreatic efficiency and the intravenous injections of glucose—have not been much used. Dr. Leyton believes that "diabetes mellitus is congenital in the same way as tuberculosis is congenital." He says: "Some members of some families possess pancreatic cells which are exceptionally susceptible to some poison, probably, but not necessarily produced by bacteria or virus." He does not mention the possibility, which Houssay's work suggests, that the disease is due to an over-action of the anterior lobe of the pituitary, and that the Beta cells are not themselves diseased. The short section devoted to danger of infection and anæsthetics is clear and most useful.

The principles of treatment are well set out and are based on Allen's original observation that "a rested pancreas may regenerate." Dr. Leyton therefore aims at keeping the blood-sugar below 0·15 g. per cent.; he does not explain why he adopts this figure, which is less than that of most normal people after a meal—i.e., 0·18 g. per cent. in the capillary blood. He allows the patient as much carbohydrate as he chooses, but divides it up between the meals according to whether one, two, or three doses of insulin are given daily. The description of the symptoms of hypoglycæmia is very good, and the differential diagnosis between coma due to hyper- and hypoglycæmia is excellent. The book is essentially a small monograph, and contains many original observations. Some of the statements are provocative and the book is not always easy to read, but all workers on the subject will find valuable help as well as stimulation in its pages.

---

1. La transfusion du sang de cadavre a l'homme

By SERGE JUDINE. Preface du Prof. A. GOSSET. Paris: Masson et Cie. Pp. 145. Fr.24.

2. Problèmes théoriques et pratiques de la transfusion sanguine

By ARNAULT TZANCK, Medécin des hôpitaux de Paris. Same publishers. Pp. 212. Fr.35.

1. Dr. Judine's book deals with a branch of blood transfusion which is wholly novel. Hitherto, in all countries blood has invariably been obtained from living donors. Dr. Judine, working in Moscow, was unable, for reasons that are obscure, to find any living donors and conceived the idea of obtaining blood from corpses. It seems improbable that, even in Moscow, the recently dead are more numerous than the still living, but, at any rate, the supply of corpses included a sufficient number of those dead by suicide, accident, or heart failure to render profitable an investigation of the possibilities. In the course of an extensive experimental and practical study many interesting points have emerged. Thus it was essential to discover whether the oxygen-carrying function of the blood of corpses was unimpaired and, if so, for how long. It was found that corpse blood produced the same degree of oxygenation in the recipient as living blood, and that a corpse could be used successfully for as long as eight to ten hours after death. For this length of time no clotting of blood took place, and the blood was not found to be toxic. The mode of death was found to influence the amount of blood obtained, for whereas 1½ to 2½ litres could be extracted from an intact corpse, less than half this amount could be got from one that had died by violent trauma. The really useful corpses, in fact, were those that had died from suicide or heart failure. The blood is obtained from the internal jugular vein with the body in the extreme Trendelenburg position. It is citrated and kept in the ice-chest until wanted and has been used after as long a period as 16 days; but it is not usually kept more than ten days. The use of corpse blood demands the same precautions and safeguards as that of living blood, and the indications are the same. The novelty of Dr. Judine's work lies in his study of corpse technique; and from our point of view it is only of academic interest, for it seems improbable that in this country it will ever be necessary to fall back, so to speak, on corpses.

2. Numerous monographs on the subject of blood transfusion have been published in recent years, and it is no longer easy to find anything to communicate that has the attraction of novelty. It is useful, however, to have summaries of the accumulated experience of specialists and Dr. Tzanck is master of his theme. The work is arranged in ten "leçons," which deal with the usual aspects of the subject, with the addition of some less usual ones, such as "difficult transfusions" with a few pages on "difficult veins," and the organisation of urgent transfusions. Here and there are found references to historical matters, but it is disappointing to find that the historical range is never permitted to extend outside France. And, indeed, this parochialism is characteristic of the whole book, so that it is difficult to discover whether the author has ever heard of any writers who have lived outside France other than William Harvey and Almroth Wright. The "bibliography" is in the same vein, including only the writings of the author and his associates. The book concludes with a series of 28 aphorisms on blood transfusion. Many of the opinions there expressed are in close agreement with those of earlier (non-Gallic) authorities, but Dr. Tzanck has presumably arrived at them all by the laborious process of personal research and observation.

Mechanism of Nervous Action

By E. D. ADRIAN, M.D., F.R.S., F.R.C.P. London: Humphrey Milford, Oxford University Press. Pp. 103. 10*s.* 6*d.*

THIS slender volume embodies the Johnson Foundation Lectures delivered by its distinguished author at the University of Pennsylvania in 1932. A brief yet informative sketch of the development of electrophysiology is given by way of introduction, after which Prof. Adrian plunges in medias res by discussing in his lucid manner the activity of single nerve-fibres and the nature of the nervous messages. He shows that changes in electric potential constitute a true index to what occurs when nerve-fibres are in action, and that impulses set up by electric stimulation of motor nerves are in point of fact identical with those arising from sense-organs or nerve-cells. Waves follow each other quickly or slowly, that is, are graded, and apparently no other kind of transmission can occur. Under natural circumstances, the effective mechanical stimulus that activates sense-organs is one of stretching the terminal part of the sensory nerve-fibre; the receptors discharge their impulses at so many a second—mostly at or above 20 a second, but also at lower rates. Here the application of his work to clinical neurology becomes evident; Prof. Adrian shows that variations in excitability and adaptation-rate exist, also in rate of conduction. He finds that different sensory fibres exercise different specific effects, though this is probably not so for pain. Non-myelinated fibres with slow conduction have endings which respond only to noxious stimuli, whereas rapidly conducting fibres are tactile only; but intermediate medullated fibres may give either a sense of contact or of pain according to the magnitude of the discharge. Prof. Adrian has not been convinced that varying sizes of sensory fibre correspond to muscle sense, touch, and temperature conveyance. His tentative conclusion is to the effect that both quality and intensity of sensation may depend, so far as concerns certain fibres, on changes in the discharge-rate.

Neurology

By Roy R. Grinker, Associate Professor of Neurology, the University of Chicago. London: Baillière, Tindall and Cox. 1934. Pp. 979. 38s.

Dr. R. R. Grinker has written a long and compendious treatise on neurology—using the term in its widest sense, for a considerable portion of the book is taken up with anatomical and physiological matter; contrasted with this, the space allotted to neuropathology is less adequate. So far as is made clear, the plan adopted by the author is to take some part of his subject—e.g., the cerebral cortex—and after discussion of its anatomico-physiological features to describe its disorders. This scheme, however, seems to have been modified so often that the reader is sometimes left rather bewildered; thus apraxia is briefly examined in connexion with the corpus callosum, nothing being said of its parietal significance. Aphasia is dealt with at the end of the chapter on the cerebral cortex; Dr. Grinker follows the conceptions and terminology of Sir Henry Head closely—and somewhat uncritically. Other parts of the same chapter discuss the symptomatology of disease of the several lobes of the brain, with the aid, in places, of large quotations from other writers—sometimes amounting to more than a page. Reference is made to anatomical niceties which are meaningless without a diagram—e.g., "Area 8 α β γ lies in the posterior part," &c., area 6a α is repeatedly mentioned but not defined except as "the greater part of the surface of the precentral area," and so on. Another peculiarity of arrangement is that to Motor Unit, Cerebellum, Muscle Tone and Posture, and Extrapyramidal Motor System, separate chapters are assigned, though the subjects are intimately interrelated; again, Spinal Tumours are placed between the sections on Spinal Nerves and the Vegetative Nervous System, Intracranial Tumours between the Cerebral Cortex and the Anatomy and Physiology of the Blood-supply to the Central Nervous System. The whole construction of the work thus leaves something to be desired.

On the clinical side the descriptions of different nervous affections are curiously unequal, and the internal arrangement of the material is often involved. For instance, the therapy of disseminated sclerosis is described before its differential diagnosis—incidentally, of the former we are told that "rest in bed and hope for spontaneous remissions are all that can be done" (sic). The account supplied of syphilitic amyotrophy (under the hybrid title of "amyotrophic meningomyelitis luetica") is too sketchy to be of value and conveys a misleading idea of its nature. A paragraph on the course of epilepsy is wedged in between descriptions of epilepsia partialis continua and of serial attacks.

The style of writing is unattractive. The reader is every now and again pulled up by a horrid blend of phraseology which is neither English nor any other language—e.g., "axis cylinder destruction with 'Abbau' attempts by microglia"; "the so-called 'anfalls paralyse' or epileptiform general paresis"; "there is a type of myelitis called *neuromyelite optique aigue*"; "Edinger's famous 'Ausbrauch's' theory may be mentioned," &c. If German or French terms are introduced they should be given in correct French or German, not a bastard variety. On p. 739 "Huebner's endarteritis" and "Heubner's endarteritis" are repeated turn about. Other errors of a grosser kind might be exemplified. But the book contains many good illustrations and diagrams, and at the ends of the chapters are useful lists of bibliographical references.

Abscess of the Brain

Its Pathology, Diagnosis and Treatment. By E. Miles Atkinson, M.B., B.S. Lond., F.R.C.S. Eng., Surgeon in charge of the Ear and Throat Department, Royal United Hospital, Bath; Consulting Aural Surgeon to the Trowbridge, Chippenham and Malmesbury Hospitals. London: Medical Publications Ltd. 1934. Pp. 289. 21s.

This work is an expansion of the Jacksonian prize essay submitted in 1926. It is based upon the study of a series of 23 of the author's own cases of brain abscess supplemented by eight additional cases illustrating kindred pathological affections of the brain and meninges. A fairly comprehensive outline is given of the pathological and clinical aspects of this condition. Inasmuch, however, as the author's own experience, as shown by the protocols of cases at the end of the book, is limited to the otogenic class of brain abscess, it has been necessary to draw extensively upon the published work of other investigators. The present state of our knowledge is adequately summarised. The discussion on treatment reveals something in the nature of a dilemma. The mortality-rates are notoriously high in all published series of brain abscess except that of Macewen, who achieved 18 recoveries in a series of 25 cases. This exceptional result appears to have excited an inferiority complex in his successors. Yet it is difficult to believe, in the face of so many acknowledged improvements in neurosurgical technique, that the modern surgeon is defeated purely on questions of technique. Mr. Atkinson ascribes a large measure of Macewen's success to the fact that his cases were selected: they were all of the chronic variety in which the abscess is walled off by a firm fibrous capsule. It might therefore be inferred that the correct policy in treating a brain abscess is to wait until the optimum moment for operation has arrived. This, however, would certainly result in the loss of many acute cases. Energetic surgical measures at an early stage seem therefore to be necessary, but when once drainage has been established Mr. Atkinson suggests that the surgeon should refrain from "meddling tactics." He is in favour of a double drainage-tube, one element of which should be large and have firm walls and the other smaller. It is then possible to dress the abscess cavity by gentle irrigation with hypertonic saline. Using such methods he has lowered the mortality-rate in his series to 55 per cent., a figure which compares very favourably with those from other sources.

By the avoidance of repetition and exhortation the work might have been considerably reduced in bulk without loss of clarity. Many of the illustrations would have gained by being enlarged so that they occupied the plates more fully; this is particularly true, perhaps, of the coloured drawings of histological preparations made by the late Mr. J. R. Ford. In all other respects the book is pleasantly produced.

Men and their Motives

By J. C. Flugel, Assistant Professor of Psychology, University College. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1934. Pp. 289. 10*s.* 6*d.*

This book is a collection of eight miscellaneous essays of which seven have previously appeared in various psychological journals. Two essays, entitled On the Significance of Names, and Some Psychological Aspects of a Foxhunting Rite, are written by Ingeborg Flugel. The two most important chapters deal with the relation of sexual and social sentiments and with the international language movement. The first opens with a comparison of the views of McDougall, who holds that the sexual and social instincts are separate, with those of Freud who regards them as ultimately identical. The author introduces the useful words homosocial and heterosocial to denote the social relations which exist between members of the same sex and of opposite sexes respectively. He notes that male homosociality is usually more developed than female, for which various causes are assigned; that the "sociality" of women is increasing, that the institution of the family may be antagonistic to that diffusion of interest which is demanded by social sentiments, and that "romantic" sexual love aids rather than impedes the formation of social sentiments. This relation points to an essential identity of sexual and social instincts, which validates the theoretical outlook of Freud rather than that of McDougall.

The essay on the international language movement seeks to interpret, in psycho-analytic terms, the unconscious emotional factors which affect the acceptance of the movement.

All the essays in the book take the form of psycho-analytic interpretations. The psychology of birth control, Maurice Bedel's Jerome (a very interesting critical study), and the character and married life of Henry VIII. are treated along these lines. Prof. Flugel writes throughout from the standpoint of an orthodox Freudian; but his essays have one inestimable advantage over those which too frequently emanate from his Freudian colleagues—they are clearly, carefully, and lucidly written. He never fails to make his meaning perfectly clear, and no sentence need be read more than once.

Studies in Blood Formation

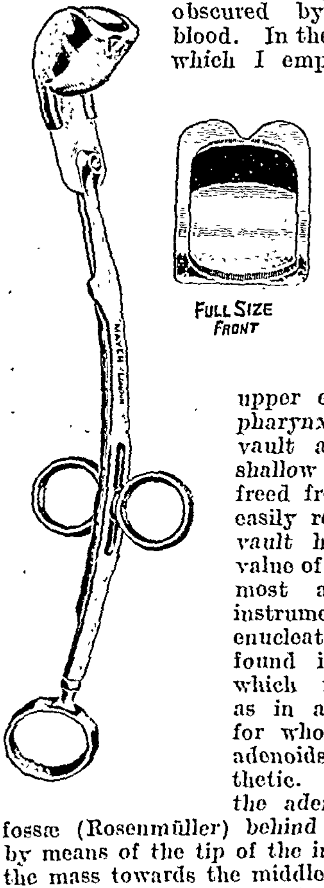
By T. D. Power, M.D., M.R.C.P., D.P.H., D.P.M., Deputy Medical Superintendent, Brentwood Mental Hospital. London: J. and A. Churchill. 1934. Pp. 124. 8*s.* 6*d.*

Dr. T. D. Power has collected into a small volume the results of his study of hæmopoiesis in rabbits under experimental conditions and in man during an attack of therapeutic malaria. As a result of his observations he concludes "it is very difficult to accept the view of Sabin and her colleagues that erythrocytes have an exclusively intravascular origin. . . . Erythropoiesis was always extravascular in character, and mature erythrocytes could be discerned lying outside the endothelial membrane which formed the capillary wall." He finds that sulfosin evokes a leucocytosis in rabbits as well as in man which he considers due to a hyperplasia of the granular element of the marrow. He suggests that the myelocytes under such stimulation arise directly from reticulo-endothelium without passing through the myeloblast stage. Thyroxine, he believes, exerts a profound stimulative effect on erythropoiesis. This action is possibly due to the fact that thyroxine hastens the process of cell differentiation. He describes an elaborate process of amitotic division in the cells of the reticulo-endothelium, but admits that "many of the findings . . . must appear to the reader as fantastic and without secure foundation . . . the phenomena cannot be detected easily, and . . . it is hopeless to search for it in the absence of first-class preparations and equipment." The book is clearly one for the specialist in hæmatology, whom it should stimulate to a closer study of the bone-marrow both in normal, experimental and pathological conditions.

NEW INVENTIONS

A NOTCHED LA FORCE ADENOTOME

Among the various references to the La Force instrument for the removal of adenoids, I have found none concerning a small alteration which may recommend itself to those using it without a good light or in a throat obscured by an accumulation of blood. In the medium-sized specimen which I employ I have had made a wedge-shaped notch which fits on to the posterior margin of the septum. When it is in position it is easy to make sure by the sense of touch that the tip is in the middle line. In by far the great majority of cases the point of the instrument reaches the upper extremity of the naso-pharynx, but if there is a vault above the choanæ the shallow notch can be easily freed from the septum and as easily returned to it after the vault has been cleared. The value of the "notch" is perhaps most appreciable when the instrument is used after the enucleation of tonsils. I have found it helpful in cases in which rapidity is necessary, as in a distinguished vocalist for whom I recently removed adenoids under a local anæsthetic. I recommend detaching the adenoids from the lateral fossæ (Rosenmüller) behind the Eustachian tubes by means of the tip of the index-finger and coaxing the mass towards the middle line before introducing the instrument. The notch must be only a shallow one, and it is only a shallow one that the structure of the instrument will stand. Its shape and position are clearly shown in the illustration.



Messrs. Mayer and Phelps, of New Cavendish-street, London, W.1, are the makers.

James Dundas-Grant, K.B.E., F.R.C.S., M.D.

⁂ We have received from Mr. Arthur Miller, F.R.C.S., an illustrated note describing a La Force adenotome notched with the same object in view. The advantages of the modification occurred independently to Mr. Miller and have been realised in his practice.—Ed. L.

LONDON: SATURDAY, JULY 21, 1934

THE COURT EXPERT

MEDICAL men are included within the definition of "expert" in recently issued Rules of the Supreme Court whereby novel provision is made for the services of a "court expert" in non-jury cases. On the application of either side the court will have a discretion to appoint an independent expert to inquire and report upon any question of fact or opinion. If the expert's report is accepted by the parties, there will obviously be a great saving in time and in the laborious preparation of evidence by the witnesses who otherwise must be called by plaintiffs and defendants. It is probable indeed that, if accepted, the report will lead to the rapid settlement of many claims. On the other hand, if the expert's report is not accepted by all parties, it is to be treated as information furnished to the court and is to be given such weight as the court may think fit. This seems to mean that the judge is free to rely upon it to the exclusion of the evidence of the witnesses produced by the parties at the trial. Each side will be entitled to copies of the report and may then apply for leave to cross-examine the court expert thereon. This cross-examination may be ordered to take place either at the trial itself (the court expert being treated as an ordinary witness and being called at such stage of the trial as the judge may direct) or before an examiner. On giving reasonable notice before the trial, either party will be allowed to call one expert witness (or, in exceptional cases and with leave of the court, two or more such witnesses) to deal with the issue referred to, and reported upon by, the court expert. But the parties who thus call expert witnesses will run some risk as regards costs. Even if they win their case they will not be allowed the costs of their expert witness unless the judge specially certifies both that the calling of such witness was reasonable and that his evidence has materially assisted the court in determining the issue. The parties will, however, be allowed the costs of obtaining the advice of their own expert (whether called as a witness at the trial or not) as to whether the action should be brought or defended, or as to whether, or how far, the court expert's report should be accepted, or as to the matters on which the court expert might properly be cross-examined.

The kind of issue in which the court expert's services may be valuable will not necessarily be a medical question. The new rules contemplate the use of court experts on any scientific matter; recourse may be had not only to medical men but also to engineers, accountants, actuaries, architects, surveyors, and other specially skilled persons. Questions of personal injuries, however, nowadays occupy a large proportion of the total of judicial time; these, and questions involving allegations of negligence in professional treatment, appear to offer occasions for satisfactory recourse to the court expert. It is true that his services are to be limited to non-jury actions, but there seems to be a general drift at present in the direction of eliminating juries if for no better reason than the fact that non-jury actions make smaller demands on judicial time. Be that as it may, the new rules offer an interesting opportunity for the medical profession to play its part in the impartial administration of justice and to remove some of the popular prejudice which the partisanship of expert witnesses has provoked. The scheme is not entirely an innovation; ever since an Act of 1852 the Chancery courts have been able to call on the assistance of experts. Its present application will be experimental; it does not yet extend to the county court. No official provision is made for a panel; the rules merely say that the court expert shall if possible be a person agreed between the parties and, in default of agreement, shall be nominated by the court. He is to receive a fee for his report and for any supplementary work required and also a fee per diem for attendance before a judge or examiner. The court will fix the amount of the fees. If the expert thinks any test or experiment necessary, he is to inform the parties and arrange with them as to his expenses and their attendance.

While an advisory committee has recommended this new use of a court expert, the council of the Law Society has found itself unable to approve the idea. The solicitors think it will be hard for "a so-called independent expert" to arrive at a fair conclusion without himself hearing what other experts and witnesses of fact may have to say—in other words he will tend to usurp functions at present exercised by the court. The council also thinks there is a danger of the court expert finding himself to be, and being regarded by the court as, a person who is not merely about to give evidence but as a person whose evidence is about to be acted upon, so that here too the court expert, and not the court, would come to try the case. The Law Society, of course, is the representative body of an extremely conservative profession which has always been able to find objections—often good enough objections too—to any proposals for shortening and cheapening litigation. The Lord Chancellor's department paid the solicitors the compliment of consulting them about the new rules but was not deterred by their disapprobation.

CANCER VIRUS

IN his Oliver-Sharpey lectures Dr. C. H. ANDREWES gives by far the most complete survey which is available of the phenomena which associate an agent very similar to a virus with the origin of malignant tumours. Since PEYTON ROUS discovered that certain bird tumours could be propagated by cell-free extracts, there has been a growing conviction on the one hand that the Rous tumours are the centre of the cancer problem, and on the other, that the study of their agents is likely to throw critical light on the nature of viruses. Such a general review as was begun last week in our columns and is concluded on p. 117 is therefore timely. Dr. ANDREWES has little difficulty in showing that the filtrable agents which may be separated from many bird tumours, whether spontaneous or produced by such substances as tar, have a close resemblance in their nature and properties to many of the viruses which are the accepted causes of a number of infectious diseases. And the more such infectious viruses are studied, the less important do their differences from visible microbes become. In a very interesting table Dr. ANDREWES draws attention to the fact that virus-like agents may cause a variety of tissue reactions ranging from pure necrosis at one end of the series to pure proliferation at the other; in the intermediate zone are conditions such as fowl-pox, molluscum contagiosum, infectious warts, and rabbit myxomatosis. If foot-and-mouth disease and vaccinia at one end of the scale are by general consent due to viruses, it is certainly difficult in the face of the graduated series presented to say that a virus is, a priori, an improbable cause of tumours.

One of the most significant qualities of tumours is their extraordinary degree of histological specificity. It is recognisable in human tumours, but their life is so short that the fact emerges in a much more striking form from the study of transplantable tumours watched through many generations. Each mouse carcinoma has its own anatomical characters which it maintains as far as the evidence goes ad infinitum. The same is true of the spontaneous and artificial sarcomata of birds. The simplest explanation is to suppose that this heritable quality is dependent on some genetic change in the cells in which the tumour begins, but this idea is plainly not tenable in view of the fact that the same constancy of structure obtains when the tumours are propagated by cell-free filtrates. On the virus hypothesis, each fresh tumour arising from a filtrate is due to the stimulation of the virus and this implies a specificity of tissue response which is much less pronounced in animals as the result of the influence of accepted microbes. It may be that the actual tissue changes are in these familiar instances directly due to some products of tissue damage—produced alike by staphylococci and streptococci for example—rather than to the actual bacterial toxins. And bearing in mind that no virus has been shown to produce a toxin, and assuming that active viruses are always intracellular, it is perhaps easier to believe that tumour viruses cause these extremely specific anatomical results. Dr. ANDREWES might also, we think, have drawn on the analogy of plant galls in which the anatomical inflammatory reaction is so specific that the species of the infecting parasite can be predicted with certainty from the appearance of the lesion.

The great practical danger of preaching any form of a parasitic theory of cancer is that thoughtless people are too apt to draw the implication that cancer is a catching disease, and to have their attention distracted from the many hygienic measures by which cancer may be prevented. There is of course no evidence whatever that cancer is infectious in any ordinary sense, and however completely the virus-like nature of the agents by which fowl tumours may be transmitted is established, there is no justification for any assumption that this agent is capable of a free and independent life. These considerations bring us to what is, we believe, the pith of the whole problem—where does the virus come from? Does it originate in the tumour or does it come from some extraneous source? Attempts to solve this problem along immunological lines, of which Dr. ANDREWES's own work forms a conspicuous part, give no clear-cut answer, and this is not surprising. It is obvious from morbid histology that malignant tumours are recognised by the normal tissues about them as in some degree foreign, and it is clear that they excite in the body a response which is both local and general. But this is no longer of any great weight in deciding whether they are wholly autochthonous or not. Modern work on the antigenic specificity of denatured and artificially compounded proteins would in fact lead one to suppose that any normal tissue which was so altered as to be a tumour would probably be antigenic to the animal in which it grew. That the cell-free agent may be antigenic is fairly clear, though the specificity of the response is obscure and muddled in any case; this provides no proof that the agent does not arise in the tumour. Dr. ANDREWES believes that it does, and in the concluding parts of his second lecture he inclines to the view that tumour viruses are integral parts of normal cells which under certain circumstances are set free to produce the characteristic changes in the cells. If that is so, the effective discovery of the cause of cancer depends on the definition of the circumstances under which these "indigenous viruses" become active rather than on the study of the viruses themselves. A great deal is known about them already and Dr. ANDREWES's lectures link up very naturally with a whole field of clinical hygienic and statistical work with which he does not deal.

PARLIAMENT AND CHILD MORTALITY

SPEAKING in the House of Commons on June 20th, on a vote for the expenses of his department, the Minister of Health stated that the death-rate of children under 5 years of age from bronchitis, measles, and diarrhœa had been cut down by more than one-half in the last 15 years. During the adjourned debate, which took place on July 3rd, the only reference which appears to have been made to the subject was an expression of satisfaction by Sir FRANCIS FREMANTLE. The fact, if it is a fact, deserves to be given prominence, because the complaint is often heard that the toddler, the child between 1 and 5 years of age, has been neglected in the administrative schemes of local authorities for the welfare of children, and because the respiratory infections have been regarded as the least amenable to control. Diarrhœa has been recognised as a vanishing disease in epidemic form, and a large part of the credit must be given to the work of infant welfare clinics in educating mothers and putting them in the way of obtaining foods for their infants which are comparatively safe from contamination. The mortality from this cause per 1000 children under 5 years of age has been almost exactly halved since the early post-war years, and there has been no recent outbreak comparable with the exacerbation which occurred in 1921. The menace to child life of diarrhœa may fairly be said to have been overcome.

Examination of the returns of death from the other two causes mentioned by the Minister inspires less confidence. Measles is a disease which is almost regularly biennial in its incidence, although its effect on death returns tends to be smoothed in statistics of calendar years by its usual prevalence in the winter, overlapping the end of one year and the beginning of the next. More important, its incidence fluctuates in long cycles, and we ought to be sure that we are not comparing figures for years on the crest of a wave with those in a trough. It is not unlikely that we are at present going through a period of rather low prevalence, so that a comparison with the early post-war years when a wave was just dying may be quite misleading. As regards bronchitis, again, it would obviously be wrong to compare the mortality in 1918–19 with any other year or group of years. For one thing there were years of epidemic prevalence of influenza; for another, the fatality among the children was relatively lower then than in other major epidemics before or since. The picture is therefore confused. But it is true that the death-rate under 5 years of age from bronchitis has been consistently running in recent years at a level half as high as that reached in 1919–20. The significance of these figures is doubtful. A far larger number of deaths under 5 years of age is now classified under the heading pneumonia than bronchitis. For instance, in 1931 12,634 deaths at these ages were attributed to pneumonia (all forms) against 2928 from bronchitis. The discrepancy was not nearly so great in 1920 and 1921; in the former year pneumonia accounted for less than twice and in the latter little more than twice, the number of deaths classified as due to bronchitis. Now, the mortality from pneumonia among children has not declined to nearly such a striking extent during the last 15 years. The rate in 1930–32 was approximately two-thirds of that in 1920–21. Indeed, in 1929, when influenza was epidemic, and with a smaller population at risk, there were more deaths from pneumonia in children under 5 than in any year since 1918.

It is important that we should be clear on these points, because practical issues are involved. In a letter which appeared in *The Medical Officer* of July 7th Prof. R. M. F. **Picken** draws attention once again to the problem of overcrowding in dwelling-houses and its effect on child life. This observer points out that it has been customary for many years to allocate less cubic or areal space to children than to adults. For instance, model by-laws for houses let in lodgings or in an improvement area issued by the Ministry of Health since the passing of the Act of 1930 provide at least 40 sq. ft. per adult occupant of a room used for sleeping purposes, but only 30 sq. ft. for each child. If it be true, as Dr. **Percy Stocks** suggests in a recent analysis of death-rates in relation to density of occupation,[1] "that the effects of overcrowding are far and away most serious at the pre-school ages," and that the selective effect of crowding upon child mortality is largely manifested in respiratory causes of death, it seems irrational to maintain a low standard of spacing for families with young children. The influence of spacing upon the incidence of droplet infections has been repeatedly shown, the most outstanding examples being found in the work of J. A. **Glover**[2] on cerebrospinal meningitis and of **Sheldon Dudley**[3] on the common infections of childhood. Overcrowding in houses is, from the medical standpoint, one of the most important aspects of the housing situation. It is understood to be the objective of the next move in the Government's housing campaign. Standards of crowding will have to be embodied either in the Bill itself or in by-laws of local application but with some national uniformity. Outside medical circles it does not seem to be realised that young children, above all others, require the maximum amount of air-space which can possibly be provided for them. It would be a mistake to attach too much significance to statistics showing the fall of mortality from the air-borne infections of childhood over a period which is short and probably in some respects exceptional.

THE NATIVE'S DOCTOR

The provision of adequate medical and sanitary services in the sparsely populated areas of tropical and subtropical countries, constitutes one of the major problems of administration. A number of difficulties stand in the way of a satisfactory solution of the problem. In the first place, there is the economic status of the population which, generally speaking, is pastoral, with a low-earning power, and is widely scattered over country in which travelling is frequently very difficult. It is for the most part impossible to expect such a population to pay for their medical services. On the other hand, the financial position of many of the countries which they inhabit precludes the provision of a fully paid Government service. Some colonies, notably French Equatorial Africa and Uganda, are developing a system of medical and sanitary services for the natives by means of a native subordinate personnel, at the head of which are European doctors. The native personnel consists of medical orderlies, a few female nurses, and men educated almost, but not quite, to the grade of medical practitioners. In Uganda these are designated senior African medical assistants. Their training is carried out at the local medical school with which is connected a fully equipped training hospital. They are licensed to practise medicine under the local laws, and are placed in charge of the larger dispensaries and also hold certain hospital posts under the European medical officers. The Uganda system has only been in operation for a short time, and it is perhaps a little early to be certain of its usefulness. So far, however, the experience with it has been satisfactory.

[2] Medical Research Council, *Special Report Series* No. 50.

[3] Ibid., No. 111.

The South African Government has recently decided to institute a somewhat similar system of training in connexion with Lovedale College, which is a Government subsidised institution for the higher education of natives. The establishment of a training school for what will be known as "medical aids" has now been sanctioned, and owing to a generous gift of £75,000 from the Transvaal Chamber of Mines it has become possible to begin training during the present year. The South African medical aids will be admitted to the medical school after passing at least what is known as the Junior Matriculation examination. They will then be given a preliminary education at the college, principally in language, physics, and chemistry. Those who in this first year prove their capacity for further education will then enter upon a four-year course in medical subjects, both theoretical and practical, at the expiration of which they will be given a joint certificate from the public health department and the Lovedale College, that they have satisfactorily completed the course, and this certificate will automatically entitle them to enter the Government medical service as medical aids. They will then be given a year of special training directed towards familiarising them with the particular work in which they would be engaged in the service—for instance, leprosy, malaria, general dispensary work, and so forth. They will not be licensed to practise medicine for gain, but only to practise under defined conditions as long as they remain in the Government service. The scale of emoluments, which includes a free house, has, it is thought, been made attractive enough to secure the best class of candidate; the salary will start with £240, rising to £300. In addition to the medical aids, it is also proposed to increase the facilities, at present inadequate, for training native girls as nurses and midwives, and also for the establishment of a lower grade of nurses, both male and female, to be known as "nurse aids."

It will be noticed that the medical assistance is stressed rather than preventive service. The ultimate aim of medical services for natives is, of course, prevention, but experience has proved beyond a peradventure that in order to inaugurate a successful preventive service in native areas, it is essential first of all to gain the confidence of the inhabitants by offering them adequate curative services. For many years to come curative and preventive services will have to march side by side and hand in hand. This point emerged clearly from the deliberations of a conference, held under the auspices of the League of Nations in South Africa in 1932, in which representatives of the medical services of most African colonies and also India took part, and it is also emphasised in the description of the subdispensary system in Uganda, by Dr. W. LESLIE WEBB, in the *Tropical Diseases Bulletin*, June, 1934. In South Africa, in Uganda, and in French Equatorial Africa, the ultimate aim is to establish rural dispensaries based on a centrally located hospital, the medical personnel of which will by periodical visits constantly supervise the work of these dispensaries. The importance of the preventive side of their work will be impressed on the medical aids, the nurses, and midwives, not only during their training but also thereafter; and it is hoped, with some justification, that gradually these dispensaries will become centres for the spread of knowledge of community and personal hygiene. They will no doubt from the very beginning be useful intelligence centres for the discovery of threatened epidemics. These experiments, in the technical if not professional education of the native, will certainly be worth watching during the next decade, and it will be of interest to note which of the various schemes in operation appear to give the best results.

A STATUTORY HOUSING COMMISSION

IN its final report[1] the National Housing Committee, whose interim report we noticed a few weeks ago,[2] has developed its plea for the establishment of a statutory housing commission with cogent argument. The proposed body would in no way supersede but would assist the local authorities to implement a policy of building on a ten years' programme over the whole country. Under this scheme the Minister of Health would retain general control over borrowings and over the amount and nature of any Government subsidies, and would also keep his quasi-judicial functions, such as the confirmation of compulsory purchase orders, clearance orders, and by-laws. But the Commission would take over certain powers: it would obtain estimates of housing needs from the various localities; would be vested with the power to approve location and coördination of sites, purchase price of land, cost of building, and type of houses to be erected; would be charged with powers to carry out duties in the matter of housing which had been neglected by a local authority; and would act as the adviser to the Ministry on technical matters. The general duties of the Commission would include making surveys of housing needs, the organisation of labour and materials, research, the formation of public utility societies, the encouragement of decentralisation, the supervision of plans for large scale reconditioning, the financing of local authorities and public utility societies at trustee rates of interest, and, most important, the control of the pace at which the programme is carried out. Precedents are quoted, for example, the Central Electricity Board, for the establishment of a body which should be independent of politics and also able to provide a continuity of policy. The case for and against the proposals is being discussed in the House of Lords as we go to press, and we anticipate that the argument that such a Commission would prove to be the best agency to secure the provision of a million new houses in ten years will not be found easy to refute.

ANNOTATIONS

A FESTSCHRIFT TO SIR ROBERT MUIR

THE last number of the *Journal of Pathology and Bacteriology,* issued on July 5th to celebrate the seventieth birthday of Sir Robert Muir, F.R.S., s wholly written by his pupils, and we notice that among the contributors are 11 professors of pathology or bacteriology. This fine volume of 253 pages, with 52 plain and coloured plates, is a noble tribute of respect and affection to one whose influence and leadership in British pathology is unique, not only as the author of deservedly popular text-books which are widely used, but as the inspirer of many able young men to lead fine lives. There are in the number 19 substantial contributions to knowledge, and between them they cover practically the whole range of topics with which pathology is concerned. Prof. M. J. Stewart, of Leeds, along with Dr. J. S. Faulds, describes the silicosis and siderosis of the lungs in Cumberland hæmatite miners; tuberculosis is generally present as well. Dr. J. W. McNee, in London, records and illustrates two remarkably large spleens which he thinks may as well be called sarcoma as anything else. Prof. J. Shaw Dunn, of the Royal Infirmary in Glasgow, contributes an interesting discussion of nephrosis and nephritis in which he correlates the morbid histology with the views of physiologists about renal function. Prof. J. H. Dible, of Liverpool, questions the correctness of the usual interpretation of fatty degeneration of heart muscle, and as the result of a number of combined chemical and histological examinations concludes that the extra fat is depôt fat brought in from elsewhere, and not the result of disintegration of the cardiac protoplasm. Dr. Ivy Mackenzie, of Glasgow, discourses on two well-studied cases of degeneration of the lateral geniculate bodies and discusses the light which they throw on the pathways of visual sensation. Prof. J. Cruickshank, of Aberdeen, has an elegant method of studying the growth and metabolism of photogenic bacteria from sea fish by photographing the colonies by their own luminosity. Dr. Sutherland Strachan analyses the incidence of malignant disease in Johannesburg and points out the relative abundance of primary carcinoma of liver in the natives, its association with cirrhosis, and its early age-incidence. Prof. J. W. McLeod and his associates at Leeds discuss the diagnostic isolation of the gonococcus, and Dr. R. Cruickshank, of Glasgow, confirms his previous suggestion that the characteristic acid reaction of the vagina is due to the fermentation of the epithelial glycogen by Döderlein's bacillus. Other papers by Dr. J. W. S. Blacklock, Prof. D. F. Cappell, Prof. C. H. Browning, Prof. T. J. Mackie, Prof. E. M. Dunlop, Dr. J. W. Howie, Dr. J. Kirkpatrick, Prof. G. H. Wilson, Prof. J. S. Young, Dr. J. A. W. McCluskie, and Dr. Janet Niven are no less interesting, and come from Dundee, Edinburgh, Newcastle, Birmingham, and Belfast, as well as Glasgow. The whole forms a record of which any school might justifiably be proud, and we doubt whether Sir Robert Muir had any other present on his birthday which pleased him as much. We wish him many happy returns.

THE POSITION OF THE AMERICAN HOSPITALS

IN the quarterly *Bulletin* of the American College of Surgeons, just issued, a statement will be found on the situation of the American hospitals under the National Recovery Programme. The statement is furnished by Sister John Gabriel, an educational director of the Sisters of Charity of Providence, and she has gone to authoritative sources for her information and reasoning. The working of the National Recovery Act was at first viewed with apprehension by hospital executives, who saw before them in its provisions the burden of additional obligations in any attempt to achieve the standards set forth for re-employment. Accordingly the committee of the American Hospitals Association, which included representatives of the Protestant and Catholic Hospital Associations respectively, decided to ask for exemption from the Act on the basis of inability to meet the necessary financial commitments. Representatives of the three associations stated their case effectively, legal support for exemption was obtained, and the three associations received an official letter that private hospitals did not come within the purpose and scope of the National Recovery Act. All hospital managements have recognised the patriotic decision of President Roosevelt to adjust the stupendous problem before him, but further financial burdens could not be borne by the majority of the voluntary hospitals of the United States, and the attempt to carry them would have led to many disasters. The arguments which prevailed for exemption were set out last September in the *Bulletin* of the American Hospitals Association by the well-known constitutional lawyer, Mr. Borden, and the point was then made that hospitals cannot be considered as industries; they are not producing organisations but charitable institutions, and the restrictions of their operations would add to the cost of illness for the public. The right of recognition by the Government that hospitals are relief agents and not commercial enterprises may not be formally admitted, and it is difficult in some cases to assert of certain enterprises that they are purely welfare institutions maintained for charitable purposes. There are difficulties ahead, but there is promise that they will be surmounted.

THE ÆTIOLOGY OF INFLUENZA

IT will be recalled that R. E. Shope has produced evidence that swine influenza is caused by the action of two infective agents, a virus and a bacterium (*Hæmophilus influenzæ suis*). A year ago Smith, Andrewes, and Laidlaw reported in our columns that the swine influenza virus would produce in ferrets a disease like that which they obtained when these animals were inoculated with a virus believed to be that of human influenza; this consisted of fever and symptoms referable to inflammation of the nasal mucosa. Shope[1] has now confirmed and extended this observation. He finds that if the instillation of swine influenza virus into the nose is made under ether anæsthesia, the ferrets develop not only nasal infection but an acute pneumonia of lobar distribution; in a number of animals this has proved fatal. The affected lungs were "deep bluish-red in colour." The histopathology was "essentially that of an edematous pneumonia"; the alveoli were distended, containing fibrinous exudate with a few cells, and the alveolar walls were much thickened. A point of great interest is that the lung lesions were apparently caused by the virus acting alone. There is thus a contrast with the disease produced by the same virus in pigs, where the presence of a bacterium in addition to the virus is necessary to produce the complete disease picture. The interest of these studies in relation to human influenzal pneumonia is obvious. More difficult of interpretation is a paper by A. Eichhorn and N. J. Pyle.[2] These workers obtained last year from Smith, Andrewes, and Laidlaw some of the virus which they had isolated from human influenza. With this they were readily able to infect ferrets at the Lederle laboratories near New York. Work on dog distemper is in progress at the same laboratories, and the ferrets recovered from the influenza were used for this distemper work. It was unexpectedly found that they were partly immune to the distemper infection; a few proved quite insusceptible and the remainder went down after a longer incubation period than usual. A second experiment confirmed this result. The authors believe that "the experimental data suggest a possible relationship between influenza in man and distemper in dogs." No evidence is offered as to the reaction of distemper-immune ferrets to the influenza virus; but the results of further studies on cross-immunity and of cross-neutralisation tests with antisera are promised. Until these are available we shall do well to suspend judgment on the possible importance of the observations. The behaviour of the distemper and influenza viruses in the ferret is, however, so entirely different, that on this ground alone a close relationship between the two viruses would be surprising.

CONGENITAL TORTICOLLIS

THERE seems to be some discrepancy in the opinions expressed by different observers on the relative frequency of the congenital as opposed to the acquired type of torticollis. It is possible that this may be due to disagreement as to the criteria on which the diagnosis of a congenital lesion shall rest; for according to Dr. Garry de N. Hough,[3] who analyses 39 cases from 1898 admissions to the Shriner's *Hospital for Crippled* Children, Massachusetts, during the years 1925 (February) to 1933 (September), a great proportion of children are not brought for treatment until infancy is well past. There seems to be a slight predilection for the right sternomastoid muscle rather than the left; the condition is as common in boys as in girls. It is noteworthy that the incidence has increased from 0·4 per cent. in 1925 to 3·5 per cent. in 1932 and 1933.

Of the different theories of ætiology advanced at different times, hæmatoma caused by birth injury, infective myositis, and ischæmic fibrosis have perhaps received most attention by recent writers. Of these theories Hough favours that of ischæmic fibrosis, and in support he cites the experiments of B. Brooks, who produced an analogous condition in the sartorius of the dog by venous ligation, and of P. N. Jepson, who found that venous blockage of a few hours' duration could give rise to persistent fibrosis. The vascular disturbance associated with torticollis in children is presumed to arise from forced positions of the head during delivery. Pathological examination of the tumour, present in the sternomastoid in a fair proportion of the cases, does not lend much support to the theory that it has originated in a hæmatoma. The histological appearances are more like those found in the brachialis in Volkmann's ischæmic paralysis. Facial asymmetry of some degree is an almost constant feature of torticollis of the congenital type; often it is very noticeable. That it is a direct result of the oblique position assumed by the head is shown by the fact of its occurrence in other conditions, such as scar contractions and tuberculous disease of the spine, in which unilateral flexion of the head is present. Correction of the deformity of the neck is followed by gradual growth of the face and ultimate disappearance of the asymmetry. In Hough's cases the recovery was complete in from two to four years. He draws attention to an apparent *increase* in asymmetry of the face in the months immediately succeeding operation; this is, of course, an illusion due to the emphasis of the deformity when the head is held upright. The late appearance of the children for treatment is rather remarkable. In Hough's series of 39 cases, only four were under 18 months of age. Hough believes that this is to be accounted for by a late development of the deformity, and not by failure on the part of the parents to notice it. If this is so, the explanation is that the injury to the muscle —if such occurs—results in deficiency in growth, and not in contraction of its fibres. Subcutaneous tenotomy is not recommended by Hough, but open division of the sternal, and, if necessary, of the clavicular, head of origin of the sternomastoid. Excision of the sternal head is not only unnecessary, but has the disadvantage of producing an unsightly prominence of the inner end of the clavicle. In the most severe cases plastic lengthening of the muscle can be done, and even division of the mastoid attachment. The results of the operation are said to be good, provided care is taken in the after-treatment. Fixation in the corrected position was applied by helmet or collar for approximately six weeks, and subsequently treatment was by active and passive stretching, corrective exercises, and massage. When the patient is fortunate enough to be brought for treatment in infancy, most surgeons agree that cure can be quite successfully effected by daily passive stretching of the muscle into the markedly overcorrected position over a period of three months.

PERSPECTIVES IN PHYSIOLOGY

LAST week we had occasion to comment on the philosophy of the professor of physiology of the University of Cambridge. His colleague at Edinburgh in his inaugural lecture, published in the June issue of the *Edinburgh Medical Journal*, has also, from a different approach, made a contribution to the problem of academic physiological teaching which merits consideration. Modern tendencies in research and modern difficulties in teaching are set out; in Prof. Daly's opinion the latter are not insuperable, and he concludes with one or two constructive suggestions. With regard to research he champions the method of studying the isolated organ, and rightly points out that, although it is placed in an abnormal environment, this is at least controllable and allows of accurate observation and repetition of experiment. Mistakes in the interpretation of results and their too precipitate application to the normal organ do not invalidate the method, which is responsible for the majority of our recent acquisitions of knowledge. With regard to teaching, he welcomes the prevailing dissatisfaction with the present system, "for progress is built on the realisation of imperfection." His proposals are two. The first deals with the teaching system in the pre-clinical subjects; he suggests a short systematic course in each subject to be followed by a correlative course:

> "If this came about, we could look forward to . . . a series of *n consecutive* lectures to be held on the anatomy, morphology, histology, physiology, biochemistry, and pharmacology, *say*, of the digestive organs, to be delivered by A, B, C, D, and E. Following each other in orderly sequence, and given by the experts in each branch, these lectures would bring together all the knowledge necessary

---

[2] Jour. Amer. Med. Assoc., 1934, cii., 2082.
[3] Surg., Gyn., and Obst., March, 1934, p. 972.

for the student in this particular field and give him an outlook which is only possible under the present mode of rigid separation by a vast amount of labour."

Prof. Daly pleads for "a trial in a small way" for this progressive scheme—progressive because it typifies the modern decline of omniscience and growth of collaboration, and because it prepares the student's mind for the synthesis of organs and systems and "subjects" into persons, which too often, in the hospital, comes as a shock to him. The second proposal relates to the student, embodying the suggestion that he comes to the university to learn rather than to be taught. Every teacher knows the difference between the man who regards his course as an opportunity to acquire as much knowledge as he can in the time, and the one who sits through it like a young bird in a nest with its eyes shut and its mouth wide open waiting for the morsels to be dropped into it. It is perhaps regrettable that the curriculum tends to be moulded to the needs of the latter, who ought not to be encouraged. However this may be, there is no doubt whatever of the excellence of the suggestion here made that:

> "Four, five, or even six . . . students get together in each other's rooms for the discussion of some pre-arranged physiological problem, say twice a week for one hour . . . they will gain a greater insight into the problems which beset them than they will as the result of many hours' reading on their own—they will certainly come to know physiology."

The same system might be applied to any branch of study. It is impossible to teach everything; beyond a certain point attempted improvement by selection and elimination defeats its object. The students at Edinburgh are fortunate in having a teacher with such a balanced outlook as this lecture displays, and others interested in the subjects of which he treats would do well to read it as an epitome of common sense.

JAUNDICE IN SYPHILIS

JAUNDICE occurs every now and again in the experience of all those who treat large numbers of syphilitics by modern methods, and it can be a very severe complication. Exactly what causes the symptom has always been a puzzle, and an exhaustive survey of the incidence of jaundice among over 10,000 cases of syphilis by U. J. Wile and W. M. Sams[1] does not clear up the ætiology. The cases were observed during a period of eight years, and it is of interest to note that they include 1040 cases of congenital syphilis. The cases of jaundice are divided up for investigation into pre-therapeutic and post-arsphenamine groups. In the first group diagnosable syphilis of the liver occurred in 91 cases (0·9 per cent.). The authors were at great pains to corroborate their diagnosis by every possible means, and believe that they have under- rather than over-estimated the actual amount of liver disease. The conditions recognised include early hepatitis (*a*) icterus gravis, (*b*) benign icterus, and chronic hepatitis (*a*) cirrhosis, (*b*) Banti's syndrome. Of the 91 affected livers only 13 gave rise to clinical jaundice; 2 patients had raised blood bilirubin, 1 gave a history of recent jaundice, and 2 had so-called catarrhal jaundice, giving a total of 18 cases of jaundice, or 0·18 per cent. of the total cases. Other authorities quoted show 0·37 per cent. (Werner) and 0·28 per cent. (Goldstein).

The number of cases treated by arsenic was 4126 in all, and of these 56 developed jaundice—i.e., 1·35 per cent. Figures from other authorities show a wide variation from 0·6 per cent. to 5 per cent. L. W. Harrison found that jaundice occurred less frequently than dermatoses but his cases were very severe and persistent. Taking the figures of Wile and Sams for both groups it will be seen that post-arsphenamine jaundice occurs 7·5 times as frequently as pre-therapeutic jaundice. On analysis it was shown that arsphenamine was to blame in twice the number of cases, calculated as a percentage, as neo-arsphenamine; that the intensive method of treatment (three injections in three days) did not produce more jaundice than the ordinary weekly method, and that no case of post-arsphenamine jaundice occurred in congenital syphilitics under 10 years of age. Further investigation showed that the cases could be divided into two groups, depending on the interval between injection and jaundice. In the early group the reaction occurred soon after an injection, either the first, when it was probably a Herxheimer reaction and the jaundice was transient, or after any dose when it may have been due to an overdose or to an idiosyncrasy. The cases of late post-arsphenamine jaundice include two-thirds of the total cases, and the authors found this to be the most puzzling group. This type of jaundice always occurred during the rest period between two courses of injections, an average interval being 80 days after the last injection. The theories as to the cause of this delayed jaundice are: (1) It may be a delayed toxic action on the liver; this is not proven by experiments, which fail to show an excess of arsenic in the excretions of these cases. (2) It may be due to a hepato-recurrence, which means that during the interval between the injections the liver has suddenly relapsed, due to insufficient treatment. It is known that mucus relapses occasionally occur, but the fact that most of the cases in this series were on some heavy metal during the relevant interval rules this out, as well as the fact that there were no cases of serological relapse. There is still another possibility (3) that these cases are merely manifestations of catarrhal jaundice occurring in a syphilitic patient. Blood counts and blood bilirubin estimations show no appreciable differences between syphilitic and non-syphilitic catarrhal jaundice, and it is difficult to exclude the possibility of coincidence. But the remarkably constant period after injection at which jaundice appears lends colour to the view that patients treated with a powerfully hepatoxic drug are more prone to exhibit the syndrome than persons with an apparently normal liver.

INTERNATIONAL CONVENTION FOR SUPPRESSING NARCOTIC DRUGS

AT the meeting of the Council of the League of Nations on May 26th, 1933, it was resolved to communicate to the various Governments a draft international convention for the suppression of illicit traffic in dangerous drugs together with a report of the Opium Advisory Committee thereon. Replies have been received from 32 Governments, 23 of whom are in favour of concluding a new convention; others have suggested modifications of the draft, while the United States and South Africa are not prepared to participate in the proposed convention. The Council, on the representation of the rapporteur, the Polish delegate, instructed the advisory committee to study the replies received and to prepare an annotated draft convention for submission to the Governments in accordance with the new procedure laid down by the Assembly in 1931. The Permanent Central Opium Board at its last meeting had its attention drawn to the accumulation of stocks of narcotic drugs which appeared to be disclosed by the statistics that had been furnished. It noted information supplied by the Hungarian Government regarding a new process for the manufacture of morphine in Hungary. It also investigated the considerable imports into Honduras of narcotic drugs of European manufacture in excess of legitimate needs, such imports having apparently been effected by false import permits. It is hoped that the new convention, when approved and ratified, will obviate a recurrence of such traffic and also secure the unmasking and adequate punishment of the master minds behind the contraband trade; these are often discovered in other countries than those actually concerned in the illicit commerce.

---

MEDICAL INSURANCE AGENCY

THE meeting of the committee of management of the Agency, followed by the general meeting, was held on July 12th, when the report and audited accounts were duly received and passed. The report showed progress in business transacted. The recommended assurance proposals dealt with during the year totalled 321, as against 302 in the previous year; during the year 900 contracts were effected, consisting of 1336 units providing for annual pension cover of £133,000. In regard to motor-car insurance the report showed that the Agency still makes an appeal to members of the profession in face of increasing competition, and while it is allowed that it has not been always possible to satisfy members in the matter of claims and settlements, in the main amicable settlements have been arranged.

After allowing for the commitments of the committee under various covenants already incurred, the sum available for distribution, in addition to the surplus unallotted from the previous year, was £1984.

The following distribution was made:—

	£	s.
Royal Medical Benevolent Fund—		
Under the 7 years' agreement	1260	0
For general purposes	200	0
Ladies' Guild of the R.M.B.F.—		
For general purposes	200	0
Earmarked for educational grants for the year 1934–35	115	0
Royal Medical Foundation of Epsom College—		
For general purposes	210	0
Further towards endowment of Dawson *Williams Memorial Scholarship*	600	0
Girls' Education Subcommittee	300	0
Royal Hospital and Home for Incurables, Putney	52	10
	£2937	10

The great value to important medical charities of the financial support of the Agency is expressed in the figures. With the allocation this year of a further £3000 (all but) to these purposes the total contribution to medical benevolence of the Agency, since its foundation 25 years ago, is brought up to £35,625 5*s.*

AMIDOPYRIN AND AGRANULOCYTOSIS

FROM a study of the 473 recorded American cases of agranulocytosis, R. R. Kracke and F. Parker[1] have come to the conclusion that the condition may be caused by any drug containing the benzamine group—especially arsphenamine and neoarsphenamine (arsenobenzol and novarsenobenzol), benzene, acetanilide, phenacetin, and amidopyrin (Pyramidon)—acting on a susceptible marrow. They find that the disease is commoner in physicians, nurses, and their relations, than in other people; for instance, it has been observed 50 times more often in doctors than in lawyers, and 200 times more often in nurses than in women school teachers. This peculiar incidence they put down to the fact that those connected with the medical profession are more likely than other members of the community to use this group of drugs. Agranulocytosis appears also to have a curious geographical distribution, most of the cases having been reported in Germany and America, with about 100 in France, whereas the disease is rare in Russia, Poland, and the Far East, and extremely rare in Great Britain. Kracke mentions 6 cases in England compared with a total of 823 in Germany and America. It is suggested that this may be due to variations in the type of drug employed in the different countries. Very few cases are recorded in negroes, and in most of these the onset was preceded by novarsenol therapy.

The Council of Pharmacy and Chemistry of the American Medical Association have been so struck by the possible association between amidopyrin and agranulocytosis that they have issued a special report on the subject by Dr. Paul Reznikoff[2], together with an official comment. Having summarised the recorded cases, Reznikoff concludes that "from the evidence at hand there can be no question that amidopyrine is very important in the production of granulocytopenia. In fact, no other agent has been found, either chemical or bacterial, which has been a factor in causing so many attacks. In the second place no definite case has been reported in which a barbiturate alone is responsible." He agrees that there are definite cases of agranulocytosis in which amidopyrin has never been taken, and that an enormous number of people who take the drug do not develop symptoms. The same is true of arsenobenzol, and clearly sensitiveness in certain patients rather than a universal action of the drug is the explanation of these findings. The Council concurs in Reznikoff's recommendation that indiscriminate administration of amidopyrin is dangerous and should be discouraged. They also draw attention to the large number of proprietary preparations which contain it.

STRUWELPETER-HOFFMANN

JUST as the author of "Alice in Wonderland" eclipsed the mathematician C. L. Dodgson, so the author of the "Struwelpeter" poems has eclipsed a distinguished neurologist and reformer of mental hospitals. It seems unlikely that in 1845, when the poems were published, Heinrich Hoffmann, lecturer in anatomy at the Senckenbergsche Institut in Frankfurt, regarded them as his most convincing claim to fame. Yet his very real services in other directions are now mostly forgotten; and this has led Dr. O. G. Foerster[3] to rescue some of them from obscurity, in celebration of what would have been his 125th birthday on June 13th. Hoffmann, he tells us, was born in Frankfurt, and after studying medicine in Halle and Paris it was to Frankfurt that he returned to take up practice. Here with five friends he founded a clinic for the poor people from the country districts round the town. In 1845, soon after his appointment to the Senckenbergsche Institut, he once more showed his enterprising spirit by starting a medical society. In 1851 he succeeded Varrentrapps as director of the Frankfurt Mental

Hospital, where he found patients in all stages of mental diseases housed together in insanitary surroundings. The nursing and supervision was bad, and no attempt was made either to cure or to help these unhappy people. After 13 years of strenuous propaganda Hoffmann succeeded in collecting the money to build a new hospital, and when it was opened in 1864 he was elected director. He is said to have treated his patients with endless patience and kindness, and for them, as for his children, he wrote poems and stories and plays. In his professional writings Hoffmann avoided hypothesis, and described rather his own experiences, experiments, and successes. His humorous works include a satire on contemporary fashionable watering-places and spas.

In 1889 Hoffmann retired, but he continued to live in Frankfurt until his death in 1894.

LECTURE NOTES BY KEATS

John Keats was born in October, 1795, and died of phthisis in February, 1821, at the age of 25. In October, 1815, he joined the medical school of Guy's Hospital, and in July, 1816, three months before he came of age, passed the examination of the Apothecaries Society and became a qualified medical man. The next year, 1817, he published his first book of verse to be followed in 1818 and 1820 by further poetry. During his brief life, Keats met with considerable hostile criticism, and his genius was perceived only by the discerning few; but posterity has given him full recognition, and the house at Hampstead where he lived is now a shrine and a museum of relics of the poet. It is to this museum that his anatomical and physiological notebook[1] was bequeathed by Sir Charles Dilke.

The poetry of Keats was said by Francis Palgrave when professor of poetry at Oxford to be characterised by "Copiousness in exquisite details, and perpetual freshness of phrase . . . Keats is hence a poet especially fit to be read as a bee tastes a flower, a little at a time, and in those pleasant places which he loves and describes so well." A search through his lecture notes fails to reveal these qualities, and it is evident that, like a sensible man, Keats, when attending professional lectures for which no doubt he had paid his fee, confined his attention strictly to business. The notes are interesting because they give some idea of anatomy, physiology, and pathology as taught at the time. The chief lecturer seems to have been "Mr. C.," later Sir Astley Cooper. A lecture on the nervous system gave occasion for the following note: "In diseases medical men guess, if they cannot ascertain a disease they call it nervous." The lecturer also points out that disorder of function may occur without "anatomy being able to discover a corresponding breach of structure." It is interesting to see that atheroma was well recognised, but attributed to "ossification" of the arteries. The condition was known to be the constant effect of age, and it was also known that in the young "a life of intemperance" might lead to it: the site of attack was between the muscular and membranous coats of the artery. The lymphatics at that time were attracting attention and were called "absorbents."

There seems to be only one point about this matter-of-fact little notebook that might give a hint that its owner was a poet. On p. 27 Keats has sketched at the margin of some rather dull notes four little drawings of flowers, one of which is standing in what appears to be a small medicine bottle. This page is reproduced as an illustration, and it has a pathetic interest in view of the following letter cited by Palgrave[2] as written by Keats shortly before his death: "How astonishingly does the chance of leaving the world impress a sense of its natural beauties upon me! Like poor Falstaff, though I do not 'babble,' I think of green fields; I muse with the greatest affection on every flower I have known from my infancy—their shapes and colours are as new to me as if I had just created them with a superhuman fancy. It is because they are connected with the most thoughtless and the happiest moments of our lives. I have seen foreign flowers in hot-houses of the most beautiful nature, but do not care a straw for them. The simple flowers of our spring are what I want to see again."

Sir William Hale-White has had the present notebook reproduced photographically and has presented copies to various institutions including the Royal Society of Medicine and the Keats Museum.

BRITISH INDUSTRIES HOUSE

OUR readers already know that in connexion with the British Industries House a medical section has been organised to afford a prominent display of hospital equipment. The official opening of the medical buying centre is taking place as we go to press (Thursday, July 19th), the inaugural ceremony being performed by Lord Derby, with a reception committee consisting of Lord Dawson of Penn, Lord Horder, Sir Humphry Rolleston, and Sir Holburt Waring. The intention at the British Industries House is to provide showrooms at rates having no close relation to economic return in order that the sale of British productions may be stimulated. With this in view the medical centre has been established, where facilities are provided in one central building for manufacturers to exhibit objects and material used in connexion with hospital equipment and administration, as well as by the medical profession generally. The important underlying hope is that this development of British industry will assist in the reduction of unemployment. From the accompanying plan of the operating theatre and ward block (designed by Messrs. Adams, Holden, and Pearson), which provide a background for many of the exhibits, it will be seen that opportunities will be found in the building for inspection of most features of hospital work.

PROGNOSIS

A Series of Signed Articles contributed by invitation

XI.—PROGNOSIS OF LOBAR PNEUMONIA

The course of lobar pneumonia is so brief and, in general, its delimitations and its accidents are so well known that in the matter of prognosis it might seem to offer fewer difficulties than other diseases of longer duration or greater complexity. An analysis, however, of the factors influencing prognosis discloses so many variables that to submit secure rules for guidance in the individual case is an impossibility. Nevertheless the experience of generations, statistical studies, and a close attention to the natural history and varying circumstances of the disease have, between them, provided us with much useful information.

The factors influencing prognosis may be divided into two categories, the general and the particular; those concerned with the disease as a whole, and those concerned with the disease as witnessed in the individual patient.

GENERAL FACTORS

In the first category we must consider broadly the observed facts relating to mortality. With morbidity we need have small concern, for the vast majority—probably 90 per cent.—of patients who recover from lobar pneumonia do so completely. It has long been appreciated that the mortality of pneumonia varies considerably with country, social environment, epidemic, age, preceding ill-health, and constitutional states, and we now know that the type of invading organism also plays its part. Pneumococcus type III. has the highest virulence, but types I. and II. account for two-thirds of all cases and of these type II. gives the higher mortality.

The general mortality as gauged by hospital figures in England and Scotland lies between 15 and 20 per cent. At Guy's Hospital during the nine years ending in 1930 the mortality between the ages of 13 and 75 years was 16 per cent. (Ryle, J. A., and Waterfield, R. L.: Guy's Hosp. Reports, 1933, lxxxiii., 389). One-third of the deaths occurred over the age of 50. There were no deaths between the ages of 15 and 20. The experience of consulting physicians in private practice is fallacious, as they are naturally called to the more anxious cases; Osler gave the mortality in his personal practice as approaching 50 per cent. (Amer. Jour. Med. Sci., 1897, cxiii., 1). In general practice the mortality-rate is lowest, and Osler, quoting the report of the collective investigation committee of the British Medical Association, which was based chiefly on such practice, gave it as 12 per cent. In the case of picked populations low figures are also the rule, and A. Abrahams (THE LANCET, 1920, ii., 543) showed the mortality for lobar pneumonia among the troops at Aldershot, during the war, to be only 10 per cent. Here the patients were mostly young, selected men, and they were immediately removed to hospital on falling sick. In France during the same period A. Malloch and J. H. Rhea (Jour. Royal Army Med. Corps, 1918, xxxi., 300) found a general mortality of 26·1 per cent. at a base hospital, with a higher rate among cases coming long distances by convoy or hospital-train, thereby confirming the general opinion in regard to the ill-effects of transferring cases excepting for short distances and in the earliest hours of the disease.

It is interesting to compare with these figures the higher rates of mortality in America, and the variations there in accordance with the class of patient studied. The mortality at the Rockefeller Hospital, according to R. L. Cecil (Brit. Med. Jour., 1932, ii., 657), is 19·5 per cent.; at the Bellevue Hospital, draining the poor areas of the city, 35·8 per cent. Writing in 1897 Osler (see above) gave the figures for the Montreal General Hospital as 20·4 per cent. and for the Charité Hospital, New Orleans, as 38 per cent. For comparison he quoted Leech's figures for British hospitals which showed a mortality of 20 per cent. at St. Thomas's Hospital, 18·6 per cent. at St. Bartholomew's, and 27·1 per cent. at the Edinburgh Royal Infirmary.

After the period of infancy the mortality of lobar pneumonia is almost negligible until adult life. Osler quotes figures between 1·9 and 3·3 per cent. In adult life it rises steadily, with a steep peak after 50 years, and in the seventh decade it is in the neighbourhood of 70 per cent. Alcoholism, obesity, diabetes, nephritis, and a recent operation all load the scales against recovery. In the recent Guy's series quoted above a general mortality of 16 per cent. is reduced to 10 per cent. if cases so handicapped and cases with serious pneumococcal complications are excluded.

It is extremely difficult to assess the influence of treatment on mortality, but early attention and good nursing in a favourable environment and without moving must partly account for the better figures of general practice as compared with any hospital series.

Recent figures collected by the Therapeutic Trials Committee of the Medical Research Council (Brit. Med. Jour., 1934, i., 241) suggest that between the ages of 20 and 40 and employing serum of appropriate type as early as possible in the disease an appreciable reduction in mortality may be achieved. With older patients and septicæmic cases the results of serum therapy are disappointing. In childhood and the adolescent period it is seldom necessary.

PARTICULAR FACTORS

Turning to prognosis in the individual we have already recognised that youth and good environment are favourable, and poor conditions and advancing years unfavourable, and that a history of alcoholism and the presence of a chronic disease or degenerative changes are strongly adverse. Of bed-side symptoms, cyanosis is adverse, delirium by no means necessarily so. Wide extent of lung-involvement, more particularly when it is bilateral, is frequently, but not invariably, of bad import. A low and especially a falling blood pressure is unfavourable. Among the more useful prognostic observations the pulse-temperature-respiration ratio should, perhaps, be given special place. A high temperature, short of hyperpyrexia, need not be disconcerting. Where parallelism between the curves of temperature, pulse, and respiration-rate is maintained or pulse and respirations are low in proportion to the temperature, the auguries may be considered good. A falling temperature with a rising pulse and respiration-rate is definitely unfavourable. A moist tongue, easily won sleep, and well-taken nourishment are encouraging signs. Restlessness and insomnia are unfavourable. A high leucocyte count in the neighbourhood of 20,000 cells per c.mm. is generally favourable, and a failure of leucocyt[illegible] ble, but, useful as it is, no abso[illegible] placed on this single prognostic test, and with intermediate figures the contribution of other clinical signs is more to be trusted. When the leucocytes range very high, say in the neighbourhood of 30,000 cells per c.mm., the likelihood of empyema must be kept in view. In a certain proportion of cases the pneumococcus can be grown from the blood stream; this finding is not necessarily adverse, but it may indicate a septicæmic state, in which event prognosis is definitely bad.

Certain complications are of greater gravity than others. Empyema developing after the crisis and beyond the period of infancy has a favourable outlook. Empyema in infancy and syn-pneumonic empyema give a high mortality. Pericarditis and meningitis usually foretell a fatal termination, but occasional recoveries are recorded.

Prognosis is especially difficult during the first two or three days of the disease, the very stage at which an accurate forecast is most desirable. In this phase we must needs rely chiefly upon our knowledge of the patient's age, type, habits, and antecedents. Osler's dictum that "the toxæmia outweighs all other elements in the prognosis of pneumonia" remains sound, and yet the assessment of the degree of the toxæmia, as apart from the effects of fever, extent of lung-involvement, fatigue, and dehydration, may tax the most experienced and physicianly mind. The aspect of the patient, the state of his skin, the state of the capillary circulation, and the "quality" of the pulse, difficult though they be to record or describe, here lend their quota to aid maturer judgments.

CONCLUSION

In summary, a good prognosis may generally be offered with some confidence in the childhood and adolescent period. Up to and above 50 the chances of death or recovery gradually become more evenly balanced; in the fifth and sixth decades the recovery-rate is in the neighbourhood of 60 per cent. After 70 years the chances of recovery fall to nearly one in four. The lean patient has a better prospect than the stout, the temperate than the intemperate. The pulse-temperature-respiration ratio and the leucocyte count taken in conjunction with other clinical signs have distinct value in prognosis. The knowledge that the disease runs a natural course but little swayed by therapeutics does not justify inaction, for it cannot be doubted that good management, without undue interference, and with or without specific aids, continues to save lives.

JOHN A. RYLE, M.D.,
Physician to Guy's Hospital.

A PROVISIONAL STABLE STANDARD FOR ANTIPNEUMOCOCCUS SERUM, TYPE II.

AND ITS PRACTICAL APPLICATION

BY WILSON SMITH, M.D. Manch., Dipl. Bact. Manch.
MEMBER OF THE SCIENTIFIC STAFF OF THE NATIONAL INSTITUTE FOR MEDICAL RESEARCH

W. FISCHER, Dr. med. Marburg
ROCKEFELLER TRAVELLING FELLOW; AND

M. LLEWELLYN SMITH, M.Sc. Lond.
ASSISTANT IN THE DEPARTMENT OF BIOLOGICAL STANDARDS, THE NATIONAL INSTITUTE FOR MEDICAL RESEARCH

THROUGH the generosity of Dr. Lloyd D. Felton, of the Harvard University Medical School, workers in different countries have been provided with a liquid bivalent antipneumococcus serum, F. 146, by means of which the type I. and type II. antibody content of antipneumococcus sera have been assayed. Felton assigned unit values to his serum, F. 146, and laboratory workers and physicians have become accustomed to the units which he proposed. In view of the fact that the serum, F. 146, is a liquid and, therefore, cannot be expected to retain its potency indefinitely, and since further supplies are no longer available for distribution, it is clearly desirable to give greater permanence and stability to the standards and units for these pneumococcus antibodies. To this end, a dry stable standard for antipneumococcus serum, type I., was prepared in this institute (Hartley et al., 1933) and assayed, as accurately as the methods at present available allow, in terms of the type I. component of the liquid serum F. 146: it was established that 0·0886 mg. of the dry stable standard for antipneumococcus serum, type I., is equivalent to the unit for this antibody as originally proposed by Felton.

The present report concerns the preparation and assay of a dry stable standard for antipneumococcus serum type II. The work has proceeded on lines similar to those followed for the preparation of the standard for type I., and with similar objects. The dry standard for type II. has been assayed in terms of the type II. component of the liquid serum, F. 146. We understand (1933) that serum F. 146 is held to contain 200 units of type II. antibody per c.cm.; on the basis of this unitage, 0·0894 mg. of the dry stable standard which we have prepared is equivalent to the unit originally proposed by Felton for the type II. pneumococcus antibody.

Preparation and Properties of the Dry Standard

The dry standard was prepared from a monovalent type II. antipneumococcus horse serum. Preliminary tests showed that the serum possessed high protective potency, and a high precipitation titre for the homologous specific soluble substance. Five cubic centimetre quantities of the serum were delivered, by means of a precision distribution apparatus, into a series of dry sterilised ampoules, dried to constant weight and sealed, the procedure followed being exactly similar to that described in the preparation of the dry stable standard for the type I. antibody (Hartley et al., 1933). The whole of the ampoules, amounting to 160 in all, are stored continuously in the dark at −2° C. to −4° C.

The sterility of the product was shown by aerobic and anaerobic cultural tests made on ampoules selected at random both before and after desiccation. The weight of the total solids in fourteen ampoules, selected at random, were found to be 0·4473 g.; 0·4473 g.; 0·4488 g.; 0·4476 g.; 0·4488 g.; 0·4489 g.; 0·4489 g.; 0·4507 g.; 0·4501 g.; 0·4487 g.; 0·4461 g.; 0·4492 g.; 0·4464 g.; 0·4446 g. The mean weight is, therefore, 0·4482 g.

The dried serum is reconstructed for use in exactly the same way as for the type I. standard, by the addition of 5 c.cm. of sterile distilled water to the contents of each ampoule. The product does not dissolve completely, a slightly turbid solution being obtained, from which, on standing, a fine white solid settles to the bottom of the ampoule. An attempt was made to determine the amount of insoluble material by weighing the quantities remaining undissolved in each of seven ampoules; the amount of insoluble material was found to be very small indeed, the average for the seven ampoules being 0·65 mg. For most of the tests in which the standard is used, therefore, the insoluble material may be disregarded, but, for precipitation tests, it is advisable to remove it by centrifugalisation.

A solution of the standard in 66 per cent. glycerol saline has been prepared for distribution to laboratories and institutions. Each 25 c.cm. of this solution contains the total solids of one ampoule, so that its potency is one-fifth of that of the solution of the standard when reconstructed by the addition of 5 c.cm. of sterile distilled water.

Comparison of Dry Standard and Serum from which it was Prepared

Precipitation tests, carried out on the reconstructed dry standard and the undried parent serum, indicated that desiccation had resulted in a loss of potency amounting to about 25 per cent. and the results of two separate mouse protection tests led to the same conclusion. Such a change has hitherto been unknown in this laboratory where many sera have been reduced to absolute dryness by the same method. There is no reason to suppose, however, that any further alteration will occur, since the serum has been dried to constant weight and each ampoule, before sealing, was filled with pure dry nitrogen gas and then evacuated; furthermore, the sealed ampoules are stored continuously at –2° C. to –4° C. No evidence of further change, since the preparation was completed, has been obtained in many precipitation and mouse protection tests.

Comparative Tests of Dry Standard Serum and Serum F. 146

The relative potencies of our reconstructed dry standard and serum F. 146 were compared by repeated precipitation and mouse protection tests.

(*a*) *Precipitation tests.*—The following optimal precipitation ratios (W. Smith, 1932) were obtained, using the soluble specific substance from type II. pneumococcus.

F. 146 .. .. .. = 1 : 23,000
Reconstructed dry standard = 1 : 4,500

These results suggest that the reconstructed standard is five times as potent as F. 146.

TABLE I

Summary of the results obtained in four experiments in which the standard serum was compared with serum F. 146.

Culture dose = 0·01 c.cm. in each experiment

Dose of recons. st. (c.cm.).	Dose of F. 146 or G.s. of st. (c.cm.).	Exp. 1.		Exp. 2.		Exp. 3.		Exp. 4.	
		Dry st.	F. 146.	Dry st.	F. 146.	Dry st.	F. 146.	G.s. of st.	F. 146.
0·000156	0·00078	100·0	100·0	..	..	..	..	95·0	89·5
0·0003125	0·00156	85·0	90·0	91·7	58·3	60·0	65·0	80·0	83·3
0·000625	0·003125	77·5	42·5	44·0	47·8	17·5	30·0	37·5	33·3
0·00125	0·00625	35·0	42·5	4·0	12·0	22·5	7·5	7·5	27·7
0·0025	0·0125	17·9	22·5	0	8·0	10·0	2·5	5·3	7·5
0·005	0·025	5·0	0	0	4·0	5·1	2·5	5·3	5·0
0·01	0·05	0	0	..	..	..	..	5·0	0

Recons. st. = reconstructed standard; G.s. of st. = glycerol solution of standard.
The figures represent percentage mortalities in groups of mice.

(*b*) *Mouse protection tests.*—Three separate tests were made in which serum F. 146 was compared with the reconstructed standard, and one test in which F. 146 was compared with the glycerol solution of the standard. Reference may be made to earlier work for a full description of the method of the test (W. Smith, 1932); suffice it to say here that in each experiment either five or seven doses of each serum, with 20 or 40 mice per serum dose, were employed. Following the indications given by the precipitation ratios, the doses of F. 146 were five times the corresponding doses of the reconstructed standard serum, whilst in the comparison between F. 146 and the glycerol solution of the standard identical doses were used. The results of all the tests are summarised in Tables I. and II.; they indicate that serum F. 146 is equal in potency to the glycerol solution of the standard and has one-fifth the potency of the solution of the dry standard serum obtained by the addition of 5 c.cm. of sterile distilled water to the contents of one ampoule.

TABLE II

Giving the "summed" results of the four comparative tests of the standard serum and F. 146

Dose of recons. st. (c.cm.).	Dose of F. 146 or G.s. of st. (c.cm).	Standard.		F. 146.

Application of the Dry Standard in Biological Assay

The following experiment provides an illustration of the practical application of the standard in the biological assay of antipneumococcus serum, type II. Through the courtesy of Dr. G. W. McCoy, director of the National Institute of Health, Washington, we have been supplied with a quantity of an antipneumococcus serum, P. 11, with a request that its potency should be determined in terms of the dry stable standard which we have prepared. It was stated that this serum was proposed as a tentative control serum for use in the United States, and that it contained from 150 to 200 type II. units per c.cm., thus being of approximately the same potency as serum F. 146.

TABLE III

Showing the results of a potency test of antipneumococcus serum, P. 11, in comparison with the dry standard serum

Culture dose = 0·01 c.cm. in each experiment

Recons. dry st. (c.cm.)	P. 11 (c.cm.).	Group mortality.		Mortality (per cent.).	
		St.	P. 11.	St.	P. 11.
0·000156	0·00078	40	39	100·0	98·0
0·000312	0·00156	39	38	98·0	95·0
0·000625	0·00312	33	34	82·5	85·0
0·00125	0·00625	21	14	52·5	35·0
0·0025	0·0125	7	9	17·5	22·5
0·005	0·025	2	2	5·0	5·0

A preliminary test indicated that the potency of P. 11 was about one-fifth of the potency of our reconstructed serum. A second test was then carried out in which six different doses of each serum were tested against a constant dose of virulent type II. pneumococci, 40 mice being used for each serum dose and a total of 480 mice being used in the test. The doses of P. 11 used were five times the corresponding doses of the reconstructed dry standard. The results of the comparative tests are summarised in Table III.; they indicate that the potency of serum P. 11 is one-fifth of the potency of our reconstructed dry standard; or, expressed in terms of the unit proposed by Felton, 1 c.cm. of P. 11 contains 200 type II. units. This result, considering the limitations of the mouse-protection method of testing, is in very good agreement with the values obtained for the serum, P. 11, in other laboratories.

Discussion

The results summarised in Tables I. and II. suggest that the assay of antipneumococcus serum, type II., is less precise than the assay of type I. antiserum. In order to obtain the same order of accuracy for type II. as for type I., a wider range of serum doses and a greater number of mice may be necessary. The results also emphasise the great advantage which a satisfactory in-vitro method—if such could be evolved—would possess over the mouse protection test.

The correlation between the precipitation and mouse protection values of the type II. standard serum and the type II. component of serum F. 146 is very close. The value of the precipitation test is further exemplified by the experiments in which loss of potency during desiccation was demonstrated. We take this opportunity of stating, however, that the limitations of the precipitation test found for type I. serum assay apply equally to the case of type II. sera; there are some sera and concentrated antibody solutions which fail to show a close correlation between their precipitation and mouse protection values.

The frequent request by laboratory workers for supplies of the standard for antipneumococcus serum, type I., indicate that this standard preparation, which was made available in 1933, is already proving of practical value. There is reason to believe that a dry, stable standard for antipneumococcus serum, type II., will be similarly useful. By its use the results obtained in laboratories and hospitals throughout the world can be directly compared. Not the least of its uses is in the further study of the methods of assay of the type II. antibody which, at the present time, lack precision. Two classes of variables inherent in the mouse protection test—namely, those of the test animals and those of the living culture of pneumococci—are not easily controlled; but the variable introduced by the instability of a liquid antiserum as the standard of reference can be entirely eliminated by the use of a dry, stable standard preparation.

The definition of a unit for antipneumococcus serum, type II., has not yet been internationally adopted; it is suggested that, pending such a decision, the unit proposed by Dr. Felton should be provisionally accepted as the basis of measurement for the type II. pneumococcus antibody. One such unit is contained in 0·0896 mg. of the dry standard antipneumococcus serum type II. which we have prepared.

The standard is freely available to all workers who desire to make use of it by application to the Department of Biological Standards, the National Institute for Medical Research, London, N.W.3.

OCCUPATIONAL THERAPY

A ONE-DAY conference on occupational therapy organised by the National Council for Mental Hygiene was held at Mansion House on July 11th. In the afternoon Sir HENRY GAUVAIN, from the chair, defined occupational therapy as "occupation carried out under direct medical control and supervision with a definite therapeutic object." It should be prescribed, he said, in the same way as medicines with regard to the requirements of the individual patient. The movement was of recent development, and in this country we were merely on the fringe of the subject. The value, both psychological and physical, of occupational treatment for all persons whose infirmities necessitated a prolonged sojourn in hospital or institutional environment was daily becoming more apparent.

IN PHYSICAL DISORDERS

Dr. J. B. MCDOUGALL, medical director of the British Legion Village, Preston Hall, gave an account of the trades and industries carried on there. The effect on the morale and general health of the men he described as amazing. Owing to the relative permanence of the patient population many highly skilled workers had been trained there, and by good organisation and good salesmanship the industries had also proved a paying proposition.

Dr. VERONICA DAWKINS, resident medical officer, Malting's Farm Sanatorium, Nayland, discussed the possibilities and limitations of occupational therapy in a sanatorium with a relatively shifting population. She laid stress on the value of handicrafts, and described a régime carefully graded according to the patients' capacity for work and exercise. In addition to handicrafts patients assisted in the utility services of the sanatorium, but all work was carefully individualised and carried out under constant medical direction.

Mr. H. J. SEDDON, medical superintendent, Royal National Orthopædic Hospital, Stanmore, stressed the importance of occupational therapy in re-educating crippled limbs, as well as its psychological effects. Controlled occupation was one of the greatest advances in therapy of modern times.

In the subsequent discussion the speaker dwelt on the value of occupation even when the period in hospital was only a few weeks.

IN MENTAL AND NERVOUS DISORDERS

In the evening, Dr. NATHAN RAW presiding, the discussion centred round occupational therapy for patients with mental and functional nervous disorders. Mrs. ELEANOR SLAGLE, secretary and founder of the American Occupational Therapy Association, said that this organisation has official recognition, and supplies trained workers to all the principal Government institutions for mental illness and mental defect in the State of New York. It also supplies workers to mental hospitals and defective colonies in numerous other States. Workers properly trained on a definite syllabus were needed; the half trained were of little use. The course in her school took two years, and included not only training in handicrafts but practical experience in their application. A considerable proportion of the nurses should have sufficient knowledge to supplement and assist the work in the wards, and, since the coöperation of the nursing staff was essential, nurses in America were given a short course of special training in occupational therapy. In the schizophrenic type of patient whose habits had deteriorated and who, if left alone would sit silent and unoccupied, slowly dementing, the value of habit training and the reawakening of interest produced by supervised occupation could hardly be over-estimated. She was convinced that treatment which brought each patient into contact with reality and obliged him to attempt to live a life approximating to the normal was a valuable weapon in mental treatment.

Dr. J. R. **Rees**, medical director of the Institute of Medical Psychology, said how greatly he had been impressed by the occupational therapy organised in American mental hospitals. It was proposed to start a school of occupational therapy in connexion with his institute. He was convinced of the value of handicrafts in the treatment of the psychoneuroses, even for out-patients.

Dr. **Elizabeth Casson**, medical director, Dorset House School of Occupational Therapy, Clifton, described the régime at her school which was connected with a home for patients suffering from functional nervous disorders, so that students were enabled to study the therapeutic application of handicrafts there, as well as in the local mental hospitals. She was convinced of the immense therapeutic value of a time-table of exercise, occupation, amusement, and rest in the treatment both of the psychoses and psychoneuroses. Nothing was worse for patients than to drift about aimlessly. A modification of the Dutch and American types of occupational therapy would probably be found best suited to English people. She was convinced that the demand for trained workers would increase as their value came to be more fully appreciated.

Dr. **Norah Haworth**, assistant medical officer at Severalls Mental Hospital, Colchester, distinguished between the employment of handicrafts in the wards and in a special occupation centre, and occupation in the utility services of the hospitals. The latter undoubtedly had a useful place in treatment provided that the occupation was fitted to the patient and not vice versa; for example, it was quite a different matter whether a patient is drafted into the laundry because she shows a special inclination for some branch of laundry work, or because there happens to be a shortage of laundry hands. She agreed with Mrs. Slagle, who had said that plaiting and weaving made an almost universal appeal. Hospitals' committees naturally required to be convinced that money was being usefully expended. A well-organised handicraft department should become almost, if not quite, self-supporting. It was of no help to the patients to be allowed to produce sloppy and badly finished articles, but the work done should, however, be carefully suited to the capacities of the patient. If committees realised that properly organised occupation was really a therapeutic measure they would be well advised not to count the cost, as it would tend to be off-set by an improvement in the recovery-rate, and in the quietude and improved behaviour of the patients. Even acute cases could sometimes be made peaceable and happy by suitable occupation.

Miss **Ruth Darwin**, a senior commissioner of the Board of Control, said that coöperation was needed from four angles: (1) the medical superintendent and his assistants; (2) visiting committees; (3) nursing staff; (4) occupation teachers. She hoped that in the near future many more medical superintendents would come to appreciate the value of occupation therapy. She was convinced that it would soon become a sine qua non of a well-conducted modern mental hospital. Occupation to be really successful must not be confined to a special room or an hour, two or three times a week, but carried on daily in the ward, and thus the nurse had an enormously important part to play. It appeared to be a psychological necessity for all humanity, whether mentally sick or mentally sound, to have some occupation with an object, and occupational therapy did not consist merely in running a needle aimlessly through a little piece of leather. If any benefit was to accrue to the patient it was essential to make him appreciate that the work must be of high enough quality to make it of real use.

MEDICINE AND THE LAW

Patient's Ambulance Journey after Childbirth

On May 12th a patient died at Crumpsall Hospital within a few hours of having been transferred from St. Mary's Hospital, Whitworth-street, Manchester, where she had just been delivered of a child. The circumstances attracted local publicity and criticism, and a committee was appointed to investigate and report. The five members of the committee included two professors of obstetrics, Prof. Miles Phillips, of Sheffield, and Prof. W. Fletcher Shaw, of Manchester. Their report exonerates the two hospitals, and, while they disclaim any authority to generalise, it obviously touches matters of some general importance. There was fortunately no divergence between the patient's relatives and the hospital witnesses on any material question of fact. Mrs. Taylor, the patient, an insured person entitled to maternity benefit, attended on April 7th at St. Mary's Hospital, Whitworth-street, where she was examined. She paid a voluntary contribution of £2 towards the expense of her confinement (expected on May 16th) at the hospital. The printed form of acknowledgment contained the following words, apparently on the back of the document: "Important. Come immediately to the hospital as soon as labour commences. In case the hospital is full the best arrangements possible in the interests of the patient will be made." The committee's report establishes the fact that neither the patient's husband nor her mother had read this printed warning. One general conclusion to be drawn from the case is that all possible steps should be taken to bring such a warning to the careful attention of the patient and of others concerned. Mrs. Taylor's condition in April was normal and satisfactory. On May 11th she felt unwell at 1 P.M., and labour undoubtedly began, but she did not go to the hospital at once. Her mother told the committee: "I purposely kept her waiting so that they could not send her back again." Later, at 5 P.M., her mother urged her to go to the hospital but the patient was unwilling. Ultimately at 5.40 Mrs. Taylor and her mother went together by tramcar to the hospital, arriving at 6 P.M. No inquiry had been made by telephone or otherwise as to whether a bed was available. As it happened, one ward, containing one-fifth of the total beds, was closed for painting and cleaning; every bed in every available ward was occupied, and there were two emergency beds occupied in each ward. The accommodation was not only full but overcrowded. An examination of Mrs. Taylor by a house surgeon, assisted by a nurse, had indicated that labour would continue for some hours. The congestion in the hospital was explained to the patient and her mother. Mrs.

Taylor was advised that it would be best for her to go to the Crumpsall Hospital; she was quite well, she acquiesced and an ambulance was ordered. In the succeeding 20 minutes events rapidly developed, and a child was born in the room where she had been examined, a room attached to the out-patients' department. The house surgeon and an experienced resident obstetrical surgeon were promptly in attendance and, notwithstanding the precipitate nature of the confinement, the patient's condition was good. She was cheerful and appeared quite unperturbed by the idea of being removed to Crumpsall Hospital. The obstetrical surgeon satisfied himself that there was no birth injury, and that Mrs. Taylor was in a fit state to be moved. At 7.25 P.M. the ambulance took Mrs. Taylor and her child with her mother and a nurse to Crumpsall Hospital where they arrived 15 minutes later. The patient was there placed in a maternity ward; she was none the worse for the journey; the nurse went back and the patient's mother returned home. Mrs. Taylor was now continuously under observation and careful treatment. At 9 P.M. the ward sister was called to her and was surprised to find obvious signs of shock. The house surgeon saw her and advised measures which were adopted and led to some improvement, but at 2 A.M. her condition became such that her relatives were sent for; she grew worse, and she died at 4.25 A.M. The committee states that at both hospitals the treatment was prompt and efficient, and that it was not for want of proper attention that Mrs. Taylor died: there being no possible accommodation at St. Mary's Hospital, the right course was to remove the patient to Crumpsall Hospital. There has naturally been public uneasiness on the general question whether it is safe and right to move a patient, either while in labour or immediately after the birth of a child, from one place to another by ambulance. The answer given by the committee, and supported by numerous statistics from hospitals of the highest efficiency, is that such removal is frequently necessitated by various circumstances, and is usually carried out with great advantage to the patient. "We find no reason to believe that in this instance a journey lasting only 15 minutes in a first-class ambulance was in any way responsible for the death of the patient." The cause of Mrs. Taylor's death the committee finds itself unable to state with certainty. After hearing the evidence of medical witnesses and particularly that of Prof. Leyland Robinson, professor of obstetrics and gynæcology in the University of Liverpool, the committee thinks that death was due to delayed obstetric shock, a rare condition which more commonly follows difficult and prolonged than simple and unassisted labours. This condition, says the committee, does rarely occur after normal labour even in the most favourable circumstances, but there are usually warning indications of its possible advent. It would not perhaps occur to a patient to inquire by telephone if accommodation was available before going to the hospital. Had such an inquiry been made in good time in Mrs. Taylor's case, it might have been possible to arrange for her to go direct to the Crumpsall Hospital.

Sarcoptic Mange Infection

In an action heard before Mr. Justice Acton on July 10th a plaintiff claimed damages for personal injuries alleged to be due to breach of warranty on the sale of a bull-dog pup. The plaintiff's case was that the pup developed sarcoptic mange three days after the purchase and that she herself contracted the same disease a few days later. She complained also that the consequent sulphur treatment had caused dermatitis, affecting her back, chest, and face. The medical evidence included that of her own doctor who said he had diagnosed sarcoptic mange by the characteristic papillary red vesicles and the absence of burrows typical in scabies. Dr. Arthur Whitfield was also called. He estimated that he had seen a hundred cases of sarcoptic mange since the war. The disease, he said, could be contracted by human beings from cats or dogs. It might develop within six days of contact with an infected animal. It was to be distinguished from scabies by the absence of burrows. It was difficult to isolate the parasite of sarcoptic mange, though not impossible, for he had himself done so. He agreed that excessive use of sulphur would produce dermatitis, the effective amount varying with different persons. At the close of the plaintiff's case the claim was settled, the defendant paying her £100.

ROYAL COLLEGE OF SURGEONS CONVERSAZIONE

THE surgeons of England on Wednesday of last week emulated the physician's art, formulating a prescription for an evening's entertainment of which the ingredients were nicely balanced. The basis of the prescription was the incitement to further effort in research provided by the varied exhibits, some grave in pathological implication, others gay as feathers of cock and hen combined; an adjuvant was supplied by appropriate lecture-demonstrations in the theatre; the mixture was given proper form and colour by the dignity of the vehicle, the stately rooms of the College; while the whole was made palatable by a well-furnished buffet. This formed an attractive meeting-place for those whose bias for the evening was social rather than technical, and certainly was one of the most if not the most popular exhibit.

It seems unlikely that any one guest found time to visit all the demonstrations, of which nearly 50 were set out, but none could come away without an increased respect for the energy with which research, especially cancer research, is being prosecuted to-day, and for the degree of coördination achieved between the agencies for its promotion. The following exhibits and demonstrations were on view:—

Imperial Cancer Research Fund.—Effect of radium on spontaneous mammary carcinomata which differ greatly in their radiosensitivity; demonstration of the presence of reducing substances in malignant tumours: evidence for the existence of hæmopoietic and cancer-accelerating factors in liver: cancer in mice and rats induced by pinene tar which is the most potent of known carcinogenic agents; the progressive growth after transplantation of a benign tumour of the rat; the technique of micro-incineration—the burning out of the organic compounds in sections of tissues at high temperatures.

Strangeways Research Laboratory, Cambridge.—The control of growth in tissue cultures by radiation: the effect of gamma rays on the whole embryo chick; experiments on wound-healing in vitro.

Stroud Laboratories, Mill Hill (Imperial Cancer Research Fund).—Growth and spread of filtrable tumours of the fowl; living cultures of normal and malignant cells under dark-ground illumination and after vital staining.

Research Institute of the Cancer Hospital (Free).—Microscopic specimens illustrating the development of carcinoma of the mamma in a castrated male mouse under the influence of œstrin: specimens of cancer-producing pure chemical compounds all being of the same chemical type and all but one derived from the parent hydrocarbon, 1:2-benzanthracene; specimens illustrating the application of fluorescence spectroscopy to the isolation of the active substance present in a cancer-producing material of industrial importance—namely, pitch.

Middlesex Hospital Research Laboratories.—Filtrable tar-induced tumours of the fowl; the action of synthetic œstrogenic and synthetic carcinogenic compounds (in association with the Research Institute of the Cancer Hospital (Free).)

Other exhibits were set out by various departments of the College and the Buckston Browne Surgical Research Farm. These included books and manuscripts illustrating the history of cancer and cancer research from 1589 onwards; reconstructions from the fragments of the skull of Piltdown man; demonstration of fossil and other prehistoric human remains, specimens of experimental and clinical work on thoracic surgery, surgical shock, and dilatation of the œsophagus and teratomata; and a new technique for dealing with paralysis of the facial nerve in man. The National Institute for Medical Research showed simple and sensitive methods for detecting the presence of acetycholine in body fluids; also some of the appliances now in use for photographing virus bodies with ultra-violet light as the invisible illuminant. St. Bartholomew's Hospital Surgical Unit showed arteriograms following injection of thorotrast; drawings illustrating the effects of irradiation on cancer of the tongue; radiograms of various types of diaphragmatic herniæ and diagrams and drawings illustrating hyperparathyroidism and Raynaud's disease. The department of physics of this hospital exhibited a new type of radiation detector, and demonstrated a newly discovered chemical effect of radiation. The anatomy department of St. Thomas's Hospital Medical School showed how retinal localisation, sharply defined, in the lateral geniculate body had been established in monkeys.

THEATRE DEMONSTRATIONS

In the course of the evening two theatre demonstrations were given to very large audiences. Dr. J. A. Murray, F.R.S., showed as a film a moving diagram of the mode of local extension of skin cancer. The initial focus is small and grows from its own resources. Extension may be by fusion of adjacent independent foci. If these develop at intervals at the periphery during the growth of a slowly growing tumour, the impression of a continuous transformation at the margins of a growing cancer may be produced. Prof. John Cunningham McLennan, F.R.S., demonstrated various aspects of the work in progress in connexion with beam therapy research at the Radium Institute.

BEIT MEMORIAL TRUST FOR MEDICAL RESEARCH

A MEETING of the Trustees of the Beit Memorial Fellowships for Medical Research was held on July 12th for the election of Fellows and other business.

The Trustees expressed their deep regret at the death on July 3rd, at the age of 82, of their senior colleague, Sir James Kingston Fowler. For 21 years in his double capacity of trustee and hon. secretary Sir James had given devoted service to the welfare of the Trust, and when enfeebled health made it necessary for him to relinquish the secretarial duties he still watched closely as trustee the progress of the work which owed so much of its success and even of its existence to his creative powers. His eager care in fostering the aims of the Trust rivalled that of the founder himself, Sir Otto Beit, during the 20 years in which the latter lived to preside as chairman of the trustees.

Fellowships through the year 1933–34 were held by 24 workers. Among the distinctions gained by past and present Fellows during the year were the appointment of Prof. E. Mellanby, F.R.S., as secretary of the Medical Research Council, and Dr. Henry Cohen to the chair of medicine in the University of Liverpool. Dr. Helen Mackay was elected to the Fellowship of the Royal College of Physicians of London, being the first woman to be thus honoured. Dr. Dorothy Russell gained the Hunter medal and triennial prize of the Royal College of Surgeons of England, and Dr. Janet Vaughan the triennial Liddle prize of the London Hospital. Dr. Maurice Stacey earned an unusual distinction as first year Fellow in being awarded the Meldola prize of the Institute of Chemistry.

The following elections to Fellowships were made:—

Fourth Year Fellowships

ROBERT HILL, M.A. Camb. To continue his research *on the properties of hæmoglobin and cytochrome. At the* Dunn Institute of Biochemistry and Molteno Institute, University of Cambridge.

LEONARD HUBERT STICKLAND, M.A., Ph.D. Camb. To continue work on the metabolism of the strictly anaerobic bacteria of the genus Clostridium. At the Dunn Institute of Biochemistry, University of Cambridge.

Junior Fellowships

SOLLY ZUCKERMAN, D.Sc. Lond., M.R.C.S. Eng. Rockefeller *Research Fellow, Yale University,* 1933–34. Proposed research: Experimental study in animals of the neurovascular control of reproductive functions. At the Department of Human Anatomy, University of Oxford.

HAROLD WILLIAMS FULLERTON, M.B. Aberd. Rockefeller Research Fellowship, Boston, U.S.A., 1933–34. Proposed research: The ætiology and treatment of hypochromic anæmia of women of the poor classes. At the Department of Medicine, University of Aberdeen, and the Rowett Research Institute, Aberdeen.

EMANUEL MANNIE LOURIE, M.B. Lond., D.P.H., D.T.M. & H. Eng. Rockefeller Research Fellow, University *of Chicago,* 1931–33. Proposed research: Studies on chemotherapy in protozoal disease. At the Liverpool School of Tropical Medicine.

JOSEPH STANLEY MITCHELL, 1st class Parts I. and II. Natural Science Tripos; M.B. Camb. Queen's Scholar, Birmingham University, 1932. Proposed research: The *effects of radiation on thin protein films* At the Laboratory *of Colloid Sciences,* University of Cambridge.

DAVID EZRA GREEN, M.S. New York, Ph.D. Camb. Research Student at Cambridge. Proposed research: *The effect of hormones and vitamins upon the metabolism* of individual organs. At the Institute of Biochemistry, *University of Cambridge.*

GORDON ALLISON GRANT, M.Sc. Dalhousie, Ph. D. Toronto. Royal Society of Canada Research Fellow, at Lister Institute, London, 1933–34. Proposed research: The metabolism of galactose and the physiological synthesis of lactose by the active mammary gland. At the Lister Institute of Preventive Medicine, London.

STUART LAWSON COWAN, B.Sc. Lond. Research worker, Department of Pharmacology, University College, London, 1932–34. Proposed research: To continue study of the chemical exchanges occurring in crustacean nerve, as a result of stimulation and oxygen want: to study the blood flow through the kidney during diuresis. At the Pharmacology Laboratories, University of Cambridge.

MAURICE JOWETT, B.Sc., Ph.D. Liverp. Assistant Research Chemist, Biochemical Laboratory, Cardiff City Mental Hospital, 1932–34. Proposed research: Metabolism of the central nervous system with reference to the effects of narcotic and basic amines in cases of mental isorder. At the Biochemical Laboratory, Cardiff City Iental Hospital.

The value of a fourth year Fellowship is £500 per annum, nd of a junior Fellowship £400 per annum.

In considering candidates for election this year the Trustees were influenced by a special desire to promote esearch in relationship to mental disease.

All correspondence of Fellows and candidates should be addressed to Prof. T. R. Elliott, M.D., F.R.S., Honorary Secretary, Beit Memorial Fellowships, University College Hospital Medical School, University-street, London W.C.1.

BUCHAREST

(FROM OUR OWN CORRESPONDENT)

DELINQUENCY AND DISCIPLINE

THE recent increase of juvenile crime in Rumania—cases of manslaughter and burglary committed by boys of secondary school age are reported—has prompted the Minister of Education to issue strict regulations regarding the control and upbringing of school-children. It has been made compulsory for them to wear uniforms, and they are also all to be numbered. Visits to cinemas have been prohibited, and they may only attend the theatre with the approval of their teacher. The Chamber of Deputies has passed a law making it compulsory for youths between the ages of 18 and 20 to take part in special military drills, which it is hoped will cultivate in them a love of order and discipline besides promoting their physical well-being. The drills will take place on Sundays and holidays, and may serve to occupy spare time which might otherwise be spent in unsuitable pastimes. Fifty drills will be held in the year, and manœuvres, lasting from 4–7 days, will take place in special camps. Badges will be awarded for proficiency, and records of attendance and progress will be kept. Parents of children who take part in the drills will be exempt from certain taxes, and two years' attendance will secure a six months' curtailment of the usual term of military service (20–36 months). Those who are not physically fit enough to attend the drills must produce a doctor's certificate, and those who absent themselves without permission will be punished by two days' hard labour for the benefit of the parish, and a fine of approximately 4*s.* which will be paid into the fund for the drills.

NEW HEALTH INSURANCE BILL

As the law stands at present any employee who is incapacitated either through illness or by an accident may claim sick benefit for six weeks no matter how many years he has been employed. A Bill has recently been put before the Chamber of Deputies which proposes that ten years' employment shall entitle the employee to eight weeks' benefit, and every further five years' employment to a further week's benefit. Thus after 30 years' employment 12 weeks' benefit may be claimed. The employee will also be entitled to a further two weeks' sick leave without pay during which time his position must not be filled and he cannot be given notice. After two years' employment maternity benefit is to be paid. An insured person who loses his employment will still be eligible for benefits for a quarter of the total period over which he has paid contributions, with a minimum of 24 months. According to present regulations the period is fixed at 30 months. The new system has been in force in Czechoslovakia for some time, where it is found to work well. Another suggested innovation is that contributors of ten years' standing, who lose their jobs at the age of 55, should, after 12 years' unemployment, automatically become eligible for the old-age pension, while for women the age limit is to be 54.

MOVEMENT AGAINST FOREIGN QUALIFICATIONS

The association of medical students of the University of Cluj, the capital of Transylvania, have presented a memorandum to M. Tatarescu, the premier, stating that graduates of the Rumanian universities find it difficult to obtain posts, as preference is given to doctors who go to study at Austrian, Hungarian, and Italian universities, where they receive degrees which are marked "valid for the Orient." The students appeal to the Government to give preference to graduates from Rumanian universities.

TUBERCULOSIS

The Minister of Health has introduced a Bill which outlines the organisation of a league against tuberculosis. The measures suggested include an energetic campaign against bad hygienic conditions which favour the spread of tuberculosis; the coordination of existing institutions; the organisation of antituberculous inoculation; propaganda and public education; the training of physicians and nurses; the establishment of dispensaries, isolation hospitals, sanatoriums, and so forth. All such institutions must be approved by the council of the league which controls all such institutions. The council of the league consists of six members who are elected for five years. The league receives the larger part of its income from the Ministry of Health, which in turn acquires it from duties on drugs, cosmetics, proprietary medicine, narcotics, State monopolies and lotteries, and the tax on alcohol. It is expected that the Bill will become law before the Chamber adjourns, and the league will thus be able to begin its work in August or September.

HOUSING CONDITIONS IN BUCHAREST

In reply to a question in the Chamber of Deputies, it was recently stated that in Bucharest there are 30,000 dwellings where 3–5 persons share one room, 13,500 where 6–10 persons share one room, and 1357 dwellings where more than ten persons live in one room. Ten per cent. of the population have a bed each, 36 per cent. sleep 2 in a bed, 27 per cent. 3 in a bed, 11 per cent. 4 in a bed, 3 per cent. 6 in a bed, and 2 per cent. 7–8 in a bed. In Rumania there are 40,500 underground dwellings and 661,400 one-roomed dwellings, most of which have windows pasted up with cardboard to keep the house warm in winter and cool in summer, and about 1,000,000 houses have floors of earth. The hygienic conditions are said to be good in only 4 of the 72 counties, in 21 they are satisfactory, while the rest are described as unsatisfactory. Owing to lack of accommodation it is possible to isolate only 20 per cent. of the patients suffering from infectious diseases. Though the law governing public health prescribes that every county should allot a certain sum from its budget for public health purposes, in the counties of Dolj, Mehedint, and Romanati not one penny is assigned to this work.

WESTMINSTER HOSPITAL.—Dr. Adolphe Abrahams has been elected dean of the medical school in succession to Sir Stanley Woodwark.

CORRESPONDENCE

THE STUDY OF CLIMATE

To the Editor of THE LANCET

SIR,—At the conference of the British Health Resorts Association two weeks ago pleas were put forward for a closer study of climate from a scientific aspect. The information which this society is collecting with regard to the special features and therapeutic value of the various spas and resorts will no doubt provide knowledge which should prove of practical value to doctors and the public. This is a step in the right direction, but it is not enough, for the information thus obtained can only be of a rather vague and general nature and unless fortified by scientific observation on the spot, whether it be spa or health resort, there can be but little hope of our being able to make detailed statements on the value of climate.

The rôle of climate in the study of disease has not to my mind been fully appreciated. It is often assumed that because people do not exhibit violent reactions to the sun, change of wind, change of humidity, &c., which sensitive subjects do, that no responsive changes are taking place via their skin and mucous membranes, which have an effect on their metabolism.

You suggested last year in a leading article on the More Exact Study of Climate (1933, ii., 546) that "human sensitiveness to physical surroundings especially in ill-health, surpass that of any instrument." If this fact were realised and accepted as true it would perhaps encourage our profession to take the real interest in the subject which it surely deserves. The human being, like the rest of the animal kingdom, is born with certain potentialities, some with strong vitality, some with weak, some with perfect mechanism, others with structural weakness, and all alike are subject from the moment of birth (and, of course, remotely before this "in utero") to the effect of environment—i.e., to food and atmospheric conditions.

Surely on ordinary reasoning climate and diet should take the first place in any scheme of research. Much attention has been given, and rightly, to the study of organisms and the gross morbid anatomy of disease, but so little encouragement has been given to investigating or teaching on the earlier important phases of disease when prevention may be possible. As educated doctors we cannot be content indefinitely with mere statements that some climates are relaxing and some bracing, some suit asthmatics, and others rheumatism; we want to try and establish why; and until the study of reactions of individuals to changes in climate as regards temperature, humidity, salt content, and ionisation of atmosphere, is attempted no answer will be forthcoming. Is it too much to hope that money will be forthcoming for clinical research on these essential problems?

Now is the opportunity for coördinating effort on the research side with the British Health Resorts Association. It should be possible, if the importance of this subject were once accepted by the profession at large, to make a start by establishing units, or teams, which include clinician, climatologist, and laboratory workers at one or two spas, and at, say, several sea coast resorts with divergent climatic conditions—e.g., Norfolk and Cornwall. Clinical material of the kind required is abundant—i.e., in convalescent homes

Such ideas have, I know, already been put forward, but they do not seem to be coming to fruition. I write, therefore, to urge the continued interest of your journal in this subject, and to help to press its claims as a subject worthy of accurate scientific observation in the relation to health and disease.

I am, Sir, yours faithfully,

Brook-street, W., July 12th. WILFRED J. PEARSON.

THE TREATMENT OF SCHISTOSOMIASIS AND ANKYLOSTOMIASIS WITH ACRIFLAVINE

To the Editor of THE LANCET

SIR,—Mr. Fisher's note on the treatment of schistosomiasis with acriflavine, which appeared in THE LANCET of April 28th, has made a noticeable move in the medical centres in Egypt. Egypt is one of the countries in which two types of schistosomiasis are common—i.e., *Schistosoma hæmatobium* and *Schistosoma mansoni*—the first being common in Upper Egypt, Cairo included, and the latter being more common in the Delta (Lower Egypt). The course of treatment suggested by Mr. Fisher is very simple, as it shortens the course to five days instead of one month under the tartar emetic treatment, and of three weeks under "Fouadin" treatment; it has the added advantage of doing away with intravenous and intramuscular injections.

Trials have been made by myself to test the effect of acriflavine on *Schistosoma hæmatobium* infection in Cairo.

Twelve cases were selected: 2 adult males, 6 boys, 1 adult female, and 3 girls. Of these cases 11 were infected with *Schistosoma hæmatobium* ova in the urine, and only one case, a girl of 11 years, had *Schistosoma mansoni* ova in the stools. The solution of Trypaflavine (acriflavine) was given according to Mr. Fisher's scale, and a dose of magnesium sulphate was given three hours after the trypaflavine.

After five doses given on five consecutive days, the examination of the excreta of the 12 cases showed the presence of abundant schistosoma ova with no alteration in the viability of the embryo. The hatching time of ova was done before and after treatment, under the same conditions, and showed no alteration. One cubic centimetre of the sediment of the urine was added to 60 c.cm. of fresh water at 50° C., and the hatching of ova observed. The hatching time after the five consecutive doses was made three days after the last dose. This was done purposely. If the hatching time test is done immediately after the last dose, while the trypaflavine is still being excreted in the urine, there will be the possibility that a long hatching time is due to the presence of trypaflavine in the urine and its effect on the ova in the bladder; simply as occurs when adding trypaflavine to an infected urine in a test-tube. Usually excretion of the stain in the urine and stools begins in about one hour after the first dose in children, and after about one and a half hours in adults, and is complete in about 48 hours after the last dose, except in children who receive a proportionally larger dose, where excretion is complete in a slightly longer time.

The only benefit of the treatment was symptomatic. The irritation in passing urine and the hæmaturia were markedly diminished. Five cases out of the 11 urinary cases were suffering much from symptoms of cystitis and hæmaturia, and all of them were relieved by the treatment, but the urine was still strongly positive for ova. My final conclusion as regards the trypaflavine treatment in urinary schistosomiasis is that it is useless as a curative agent but it ameliorates the symptoms of cystitis.

Six patients of the 12 mentioned before were ositive for ankylostoma ova in the stools. By a ood chance I noticed that repeated examination f the stools after the course of trypaflavine treatment did not show any ankylostoma ova in the stools xcept in one case in which it was positive after he fourth examination. This shows that trypalavine is effective in treating ankylostoma. Even he positive case mentioned was only positive after he fourth examination, showing that the number of ankylostomes in the intestine was much reduced. Other cases of ankylostoma infection were selected for trial. Up till nów 10 cases in all have been given the trypaflavine treatment; 6 were given 5 doses each on 5 consecutive days, and 5 out of these were negative after repeated examinations. Two were given 2 doses each in 2 consecutive days and their stools were persistently negative. One was given 1 dose and was found negative and 1 with a very heavy infection was given 4 doses on 4 consecutive days and was still positive. So this gives a rate of 2 failures in 10 cases; a very promising result. Upon other worms—e.g., ascaris, oxyuris, &c.—which happened to be present with ankylostoma the results were not satisfying. Now trials are being made to estimate the proper dose and number of doses necessary for treating ankylostoma.

This letter is only intended as a preliminary note, for further investigations upon the subject will be made.—I am, Sir, yours faithfully,

A. FAKHRY, M.B. Cairo,
P.M.O., Bilharzia and Ankylostoma Hospital
July 9th. (Shoubra), Cairo.

SPECIFIC SUPERSENSITIVENESS

To the Editor of THE LANCET

SIR,—Drs. Grant and Scott, in discussing the case of acute serum shock that they report in your columns last week, bring forward evidence that natural supersensitiveness is not specific. The same syndrome of collapse resembling anaphylactic shock—cough, sudden syncope, cyanosis, and feeble pulse—has been reported twice after intravenous injection of quinine-urethane for varicose veins,[1] [2] and both patients gave a positive skin reaction to quinine when subsequently tested. Many thousands of quinine injections must have been given up to date, but only these two cases of collapse have reached the literature. A much larger proportion of patients, however, are sensitive to quinine taken by mouth or applied topically. Bram, while developing his quinine-tolerance test for hyperthyroidism, found 4 patients out of 500 who developed erythemata.[3] Local dermatitis after the use of after-shave lotion containing quinine has been noted in about ½ per cent. of those indulging in this luxury.[4] And cases of urticaria and sneezing have been frequently reported after the use of quinine. These non-specific reactions lend support to Prof. Topley's claim[5] that drug idiosyncrasies are manifested by a symptom-complex, bearing no relation to the substance evoking it. It has been shown that many of the skin eruptions and the coryza following the exhibition of quinine can be avoided by using the dextro-rotatory isomers.[6] This is not the whole story, however, for a certain number of persons are sensitive in a different way to quinine; they do not react in the non-specific allergic manner, but develop the distinctive toxic picture of the drug—tinnitus, deafness, restriction of the field of vision, and labyrinthitis—with an unusually small dose.

Supersensitiveness, to drugs at any rate, must be classified into two groups: one, the non-specific allergic syndrome, including the rare cases of anaphylaxis which appear to follow parenteral therapy; the other, the "specific" syndrome, which manifests the specific selective action on the tissues characteristic of the drug in question.

I am, Sir, yours faithfully,
Bristol, July 13th. FRANK BODMAN.

THROAT AFFECTIONS AND THE O.T.C. CAMPS

To the Editor of THE LANCET

SIR,—On July 30th the various Officers' Training Corps will commence a ten days' camp round Aldershot. In view of the numerous septic throats which have been prevalent during the droughts of the recent winter and the present summer, would it not be a wise precaution if the authorities arranged for a morning and evening "gargle" parade? This could be very easily done, especially by means of perborate of soda which is a most efficacious and harmless agent. All those who have served in camps in the neighbourhood of Aldershot know well the irritating and infective dust encountered there.

I am, Sir, yours faithfully,
Harley-street, W., July 14th. MACLEOD YEARSLEY.

URTICARIA FROM BEE-STINGS AND FISH-POISONING

To the Editor of THE LANCET

SIR,—Two sisters who kept bees, instead of acquiring immunity to the poison, became highly sensitised. The younger, aged 27, first had charge of the bees and was often stung, but only slight local irritation ensued, which soon passed off. Then towards the end of the second season she had two violent attacks following bee-stings. About 15 minutes after being stung intense urticaria started all over the body, including head and limbs, accompanied by a feeling of serious illness, fainting, and collapse. A doctor was called on the second occasion, and on his advice she kept away from the bees.

The elder sister then took charge and, apart from trivial local irritation, bee-stings had no unpleasant effect during the first two years. About mid-season of 1932 a very serious attack occurred, said to be due either to food-poisoning or to a bee-sting, or to both combined. The bees were avoided for the rest of that year and during 1933. She took charge of them again in April, 1934, and had one sting on a leg, about mid-May, with only slight local effect.

Three bee-stings on May 30th (two on left hand and one on left leg) were followed within 20 minutes by intense urticaria from head to foot. Irritation began on the scalp and spread rapidly, accompanied by a "terrible cough," and much cardiac and mental distress. She took two tablets of calcium sodium lactate powdered in water when the irritation began. But as the general condition continued to get worse, 1 oz. of Phillip's milk of magnesia was given in some water. Very marked relief of the intolerable itching, and of the cough, cardiac, and mental distress began within five minutes after taking the magnesia. She was quite comfortable two hours later and slept well. There was slight œdema of the dorsum of the little change in the number found in the streets, on staircases, and under arches.

It is noteworthy also that the number using voluntary societies' homes and shelters is on the increase. Such homes include the Cecil Houses for women established in various parts of London through the efforts of Mrs. Cecil Chesterton, and in view of the reasons which led to this undertaking (see THE LANCET, 1927, i., 659) we are glad to learn that the Council's public assistance committee proposes to give detailed consideration to certain aspects of the present census in its relation to the general question of the homeless poor. The problem is a difficult one, as was obvious from the report on common lodging-houses issued by the medical officer of health in 1927, and reviewed in our columns (loc. cit.). But in spite of comparatively reassuring figures those familiar with the neighbourhood of the Embankment during the past winter will find difficulty in believing that it has yet been adequately solved.

The Census

H.M. Stationery Office have now issued, at 30s., a volume containing the occupations statistics derived from the 1931 census of England and Wales. Besides figures for the country as a whole, data are furnished for 12 geographical regions into which the country has been divided, and also for counties and large urban areas. The system of classification of occupations used for the 1921 census has been substantially retained, and is described in detail, with an alphabetical index of about 35,000 occupational terms, in a separate volume entitled "Classification of Occupations" (12s.).

An innovation has been introduced by the inclusion of census statistics of persons out of work at the date of the census. The classifications of such persons embrace all classes of the community, including those outside as well as those within the scope of the various insurance schemes. In the present volume the reader will find comparative material by means of which the larger features in the occupational changes which took place between 1921 and 1931 may be studied. The general character of these changes, with their drift away from agriculture and heavy industries, is, of course, already well known.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 7TH, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 1 (last week 1); scarlet fever, 2245; diphtheria, 1114; enteric fever, 35; acute pneumonia (primary or influenzal), 601; puerperal fever, 43; puerperal pyrexia, 123; cerebro-spinal fever, 15; acute poliomyelitis, 5; acute polio-encephalitis, 2; encephalitis lethargica, 8; dysentery, 7; and ophthalmia neonatorum, 88. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on July 16th–17th was as follows: Small-pox, 0 under treatment, 0 under observation (last week 1 and 0 respectively); scarlet fever, 1586; diphtheria, 1514; measles, 1061 (last week, 1221); whooping-cough, 300; puerperal fever, 27 mothers (plus 9 babies); encephalitis lethargica, 269; poliomyelitis, 2; "other diseases," 215. At St. Margaret's Hospital there were 15 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there were no deaths from small-pox, 1 (0) from enteric fever, 17 (3) from measles, 4 (0) from scarlet fever, 21 (5) from whooping-cough, 32 (11) from diphtheria, 35 (6) from diarrhœa and enteritis under two years, and 15 (1) from influenza. The figures in parentheses are those for London itself.

Of the deaths from measles 3 were in Tynemouth and 2 in Liverpool. Whooping-cough caused 3 deaths in Birmingham and 2 in Manchester. Four fatal cases of diarrhœa and ent were reported from Birmingham, 3 in Manchester, and 2 in Bradford, Newcastle-upon-Tyne, Salford, and Wolverham

The number of stillbirths notified during the we was 251 (corresponding to a rate of 37 per 1000 to births), including 42 in London.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

THERE will be ten vacancies for medical officers i September next. Candidates must be less than 28 yea of age, and the term of service will in the first place b three years. Further particulars are given in our adve tisement columns.

S. G. French to be Surg. Lt. (Short Service).

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. (D) J. E. Daniels to be Surg. Lt.-Comdr. (D).

Surg. Sub-Lt. H. R. Vickers to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS

H. V. D'A. Iles to be Lt. (on prob.), and is secd.

RESERVE OF OFFICERS

Lt.-Col. A. J. Williamson, having attained the ag limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY

Lt.-Col. H. F. Wilkin (ret. T.A.) to be Lt.-Col.

H. B. Lee (late Offr. Cadet Serjt., Univ. of Lond. Contgt., Sen. Div., O.T.C.) to be Lt.

H. S. H. Gilmer to be Lt.

INDIAN MEDICAL SERVICE

Lt.-Col. A. A. McNeight to be Col.

Lts. to be Capts.: W. A. N. Marrow, H. B. Macevoy, M. M. Mansfield, J. Guthrie, W. J. Stewart, J. D. Grant, W. H. G. Reed, T. E. Palmer, D. G. McCaully, F. C. Jackson, J. W. Bowden, J. M. Sclater, J. D. Murdoch, C. F. Garfit, D. K. L. Lindsay, D. R. Tweedie, A. T. Andreasen, W. S. Morgan, M. S. Purvis, M. E. Kirwan, R. D. MacRae, C. J. H. Brink, W. Mackie, G. S. N. Hughes, J. W. Richmond, A. D. Barber.

Lts. (on prob.) to be Capts. (on prob.): M. Ata-Ullah, G. B. Thomas, J. White, H. A. Ledgard, T. F. O'Donnell, W. W. Laughland, S. Ahmad, C. C. Kapila, F. W. Allinson, F. R. Cawthorne, W. B. Stiver, F. V. Stonham, J. M. Mathew, J. G. Stonham, L. Feinhols, G. F. Harris, F. W. Whiteman, F. C. Leach, and R. D. Scriven.

ARMY IN INDIA RESERVE OF OFFICERS

Capt. M. L. Gujral relinquishes his commn., on appt. to the I.M.S.

ROYAL AIR FORCE

Flight Lt. J. MacC. Kilpatrick is promoted to the rank of Squadron Leader.

Flight Lt. D. Loughlin is transferred to the Reserve, class D.

Dental Branch.—Flying Offr. D. I. Malcomson is promoted to the rank of Flight Lt.

SPECIAL RESERVE

Flying Offr. R. H. Vartan is promoted to the rank of Flight Lt.

DEATHS IN THE SERVICES

The death is reported of Surg.-Lieut. (D) J. W. Robinson, R.N., one of a party of officers from H.M.S. *Devonshire* who, while sailing opposite the island of Samos on July 14th, were fired upon by Turkish sentries. Surg.-Lieut. Robinson was hit and lost overboard.

Lt.-Colonel Jeremiah Penny, I.M.S., retired, who died on July 7th during a voyage home from India, aged 70, qualified with the double English diplomas in 1887, having studied medicine at King's College Hospital, where he afterwards held several junior appointments. He was also House Surgeon at St. Peter's Hospital for Stone. In 1891 he received his first commission in the Indian Medical Service, and was in Burma in 1892–93—Chin Hills (medal and clasp). He reached the rank of Lt.-Col. in 1911.

OBITUARY

ILLIAM WILFRID KING, M.B., Ch.B. Bristol, F.R.C.S. Edin., F.C.O.G.

THE death occurred on July 9th of Mr. W. W. King, prominent gynæcological surgeon in Sheffield, ho had played a great part in the hospital developents of the city during the past 20 years. He was his 52nd year.

King was educated at Stonyhurst, received his rofessional training in the medical school of Bristol niversity, took the English double diploma in 906, and obtained the F.R.C.S. Edin. in 1908. wo years later he graduated as M.B., Ch.B., at ristol. He was for a time house surgeon at the oyal Hospital, Sheffield; he then became resident bstetric officer at the Royal Infirmary, Bristol, ut continued his association with Sheffield by becomng house surgeon and, later, registrar to the Jessop Hospital for Women; he was then duly appointed surgeon to the hospital and lecturer in gynæcology and obstetrics in Sheffield University.

King, prepared by long residence at a special women's hospital, seized the opportunity to increase his knowledge in general pathology by taking the post of clinical pathologist at the Royal Infirmary, Sheffield, which he occupied from 1911 to 1920. He was soon recognised among his colleagues and the public for his sound gynæcological work. He became an acknowledged expert in his specialty, not only locally but over a wide area, and was an exceptionally successful operator. His special interest was the investigation of the causes, near and remote, of puerperal fever. He wrote on this subject and on pelvic adenomyomata in the *British Medical Journal*, and contributed other papers to the *Journal of Obstetrics and Gynæcology*, and to the transactions of the North of England Obstetrical and Gynæcological Society, in the service of which body he served as secretary and president. The transactions of that society from 1912 onwards contain many records of his valuable papers and communications, and of the remarks, variably apposite and illuminating, with which he reinforced the society's discussions. Widely read, keenly observant and alert, with a very large clinical experience and deep interest in its pathological aspect, he was always prepared to discuss usefully any question involving his specialty. The paper on the clinical symptoms of pelvic adenomyoma was read at the annual meeting of the British Medical Association at Bradford in 1924, and has been often drawn upon by other writers on that subject. Many authorities also consider his observations and views on the difficult subject of puerperal sepsis to be of the greatest importance. For the past seven years he had controlled 30 lying-in beds at the Nether Edge Municipal Maternity Hospital, thus adding to his experience and responsibilities. He was an examiner in his subjects at Sheffield University and the Central Midwives Board, and had been elected F.C.O.G. for his valuable work in connexion with the foundation of the new College.

King had an extremely critical sense and accepted nothing unless he could convince himself that it was right and logically sound. This attitude of mind rendered him most valuable as a colleague, and though he was often in disagreement, yet, on the other hand, he was always ready, if necessary, to acknowledge he was wrong, and when once convinced gave his whole-hearted support to further the project under consideration. By a tragic coincidence, it was during the investigation of an outbreak of puerperal sepsis that he developed a streptococcal infection of the throat, from which arose the septicæmia which, after several weeks' illness, caused his death.

King was a member of a well-known West Country Catholic family, was deeply religious, and the Catholic community of Sheffield have lost one whom it will be difficult to replace. This was apparent from the large congregation which attended the Requiem Mass held at St. Marie's Church, Sheffield, and was present later at the interment. The medical and lay community of Sheffield have lost a valued member and the medical students an inspiring and forceful teacher. His loss will be especially felt by the board, staff, and patients of the Jessop Hospital, for which institution he had done so much faithful service.

FRANCIS EDWARD FORWARD, O.B.E., F.R.C.S. Eng.

THE death of Mr. Francis Edward Forward, which occurred on July 2nd at 12, West Park, Mottingham, London, S.E. 9, followed on an illness of over 18 months. Born in 1866 at Chard, Somerset, he received his general education at Sherborne and proceeded for medical training to St. Thomas's Hospital. He qualified with the English double diploma in 1889 and took the F.R.C.S. Eng. in the following year. He now joined the Colonial Medical Service as medical officer of the Holberton Hospital, Antigua, West Indies, a post which he held from 1891 for the following eight years, and was made a member of the Legislative Council of the Leeward Islands, of which Antigua is the seat of government. In 1899 he transferred to the Home Office Department and held various appointments in the Office until he retired in 1930, when he received the distinction of O.B.E. Mr. Forward leaves a widow and one son.

NEWMAN NEILD, M.B., Ch.B. Vict., F.R.C.P. Lond.

SENIOR PHYSICIAN, GENERAL HOSPITAL, BRISTOL

WE regret to announce the death of Dr. Newman Neild, senior physician to the Bristol General Hospital, which occurred suddenly on July 4th at his house, Richmond Hill, Clifton, Bristol.

Newman Neild, a Manchester man, was the son of the Principal of Dalton Hill, was educated at Bootham School, and pursued his medical curriculum at Victoria University, Manchester. He qualified in 1897 with the double English diploma and became house physician to the Royal Infirmary, Manchester; he then, in London, filled the important junior posts of house physician to the Brompton Hospital for Consumption and to Great Ormond-street Children's Hospital. He now settled in Bristol, and was appointed in 1901 assistant physician to the General Hospital, and in this capacity gained a sound reputation through his prolonged work in the X ray department, where he worked for 17 years with assiduity. He communicated to THE LANCET in 1909, in association with Dr. E. V. Dunkley, an interesting paper on the rôle of saliva in the transmission of tubercle, and their observations, which were considerably quoted 25 years ago, helped to make public authorities recognise the dangers of the then prevalent and nasty habit of expectoration in public vehicles. On promotion to full physician Neild took the diploma of M.R.C.P. Lond., and in 1928 was elected F.R.C.P. At the Bristol Medical School Neild lectured for a long period in pharmacology and therapeutics, in which subjects he was recently an examiner for the diploma of the English Conjoint Board. He was an able draughtsman, and in conversation would often pull out paper and pencil and illustrate his views on the points under discussion. He was interested in old books, especially those relating to botany. He held many important posts in connexion with the British Medical Association, and enjoyed well-merited esteem for much all-round work, public and professional.

DAVID ROSS, M.D. Aberd.

Dr. David Ross, who died at his house in Kingsland-road, London, on July 4th, received his early education in Aberdeen, studied medicine in the University of the City, and also at St. Bartholomew's Hospital, London, and graduated M.B., C.M. Aberd. in 1894. In 1898 he obtained the M.D. Aberd. with highest honours, and shortly afterwards settled down to practice in the north of London, where he enjoyed a wide reputation for efficiency and public spirit. He did valuable service for many years for the British Medical Association, being at different times a member of the Representative Body and of the Council. He was for a time honorary medical officer to the Metropolitan Hospital, he served as President of the Hunterian Society, and was vice-chairman of the National Service Medical Board of the City of London. He was also for a period examiner in materia medica at the University of Aberdeen. Dr. David Ross was a very able man, well read and considerably travelled, and his death has been felt as a loss by a large circle.

CHARLES JOSEPH HEATH, F.R.C.S. Eng.

The death occurred on July 13th at his house in York-terrace, Regent's Park, London, of Mr. C. J. Heath, who was principally known in connexion with methods devised for the remedy of chronic suppuration of the ear, and the restoration of hearing.

Charles Joseph Heath was born in 1856, and educated at Totnes Grammar School, proceeding for his medical training to St. Bartholomew's Hospital. He was a successful student from the beginning, winning the Treasurer's Prize in practical anatomy for first year students, and the Foster Prize awarded for similar proficiency to more advanced pupils ; the result was an appointment as prosector at the Royal College of Surgeons of England. He took the diploma of M.R.C.S. in 1884, and the final Fellowship in 1886. He was then, for a period, house surgeon at the Preston Royal Infirmary, but continued his interest in structural anatomy, and decided to specialise in otology, as providing an outlet for his skill in dissection. He returned to London, and was appointed assistant surgeon to the Central London Throat, Nose and Ear Hospital, and later surgeon to the Golden-square Throat, Nose and Ear Hospital, his services being also requisitioned by the Metropolitan Asylums Board.

The procedures which he devised for the cure of chronic suppuration of the middle ear, without removal of the drum or ossicles, were described in a paper read before the Otological Society in 1904. Accompanying the reading of this paper he showed several patients who had been operated upon by his modification of the radical mastoid operation. This paper was itself a sequel to one read before a local medical society previously in which he had endeavoured to demonstrate the good results of his operative measures. In the interval he had performed his operation a hundred times with such a measure of success that he was, he said, convinced that it, possibly with slight modifications, would ultimately be adopted as a means of restoring hearing to a large number of persons afflicted with suppurative disease. But although his views led to close discussion he made few disciples among the leaders of his specialty. In 1907 he described in our columns ten cases where the cure of chronic suppuration of the middle ear had followed the employment of his methods, neither the drum nor ossicles having been removed, and the hearing remaining good. He continued to report on the favourable results of further series of patients, and at a debate before the British Laryngological, Rhinological and Otological Association in the same year he met with more support than he had previously experienced, though words of caution were uttered with regard to the dangers that his variation in the radical mastoid operation might bring about. He had a large practice as an aural surgeon, and spoke at congresses and wrote in the transactions of societies and elsewhere, with conviction, on his subject. During the war he was attached as aural surgeon to one of the military hospitals, and his mechanical aptitude was here displayed in modifications of the gas helmet, while he also put forward an altered design for army boots.

Heath was a keen sportsman, and a member of the Wild Birds Advisory Committee of the Home Office. He was devoted to both fishing and shooting, and in connexion with the latter sport it is characteristic of him that he invented a wild-fowling gun. He was a widower, his wife, who died in 1930, being the daughter of Colonel J. J. Wilson, he is survived by two daughters.

ALEXANDER THEODORE BRAND, M.D.

The death of Dr. Alexander Theodore Brand at the advanced age of 81, which took place at Great Driffield, Yorks, will be deeply regretted by a large circle of patients and personal friends. To one of these we owe the following biographical note.

"For some years Alexander Brand was engaged in business in Aberdeen, but he always had a great desire to study medicine, and in 1877 he began his course at the University of Aberdeen, being a good many years older than his fellow students, and the writer of these lines, who began his curriculum in the following session, admired at the time, and has ever since from a fuller experience of life continued to admire, the good fellowship and understanding which always existed between him and his juniors. This was a state of affairs which was to the credit not only of Brand but of the youngsters who worked alongside of him. He qualified as M.B., C.M. in 1881 and proceeded to the degree of M.D. in 1884. Some time was spent in the London and Vienna schools and then he became associated with the late Dr. Eames in his practice at Great Driffield, and when Dr. Eames left the district he carried on the practice for some time alone and later in association with his relative Dr. J. R. Keith. He was not a frequent writer, but he made certain communications in support of the infective nature of cancer on which he held strong views.

When Brand was in business in Aberdeen he was a keen volunteer and held commissioned rank in the 1st Volunteer Battalion of the Gordon Highlanders. Later he became Major in the R.A.M.C. and was O.C. 2nd Field Ambulance East Yorks Volunteers, and retired with the rank of surgeon major (V.D.). He was much interested in the work of the St. John Ambulance Association and he was an officer in the Order of St. John. For many years he was the medical officer of the Driffield and District Poor-law Infirmary. He was a man of fine presence, great charm of manner, courteous, kind, and absolutely straightforward in his dealings."

SIR JAMES KINGSTON FOWLER.—The accidental mutilation of a sentence in the obituary notice which appeared last week of Sir James Kingston Fowler must be corrected. The notice states that *not many of his colleagues on the Beit Foundation* knew him personally; the exact reverse was the case, and the sentence should have run "not many of the other Fellows knew him personally." We much regret the error.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Milk Bill and the Tuberculin Test

IN the House of Lords on Thursday, July 12th, Earl DE LA WARR, Parliamentary Secretary to the Ministry of Agriculture, moved the second reading of the Milk Bill which has already passed through the House of Commons. He said that the Government could feel that in this Bill they were putting before their Lordships a really balanced policy for the milk industry. It could be divided into three parts. The first was an attempt to save the industry and stave off ruin by putting a bottom into the market. That scheme would cost something over £1,500,000 per annum. That payment would operate over a period of two years, and after that period if prices had risen to a certain height these payments would have to be repaid to the Exchequer. The second and third parts of the policy constituted an attempt to increase the production of milk in this country. The first method of doing that was by cleaning up the herds from the fell disease of tuberculosis, which was, unfortunately, too common among cows, and the second method was a scheme of milk publicity, of spending £500,000 a year for the next two years very largely on increasing the supply of milk in schools for school-children.

Lord MARLEY said that Earl De La Warr had said that they must improve the quality of milk and increase the consumption and he proposed to spend public money in doing those two things simultaneously. Was he going to use public money to advertise immediately by an increased consumption of rotten milk which was now being distributed or was he going to wait until the milk was really good before he advertised by an increase in the consumption by school-children? The noble lord should have said that the quality of milk in this country was probably less good than in any modern civilised country. According to the Report of the Committee on Cattle Diseases, at least 40 per cent. of the cows in dairy herds in this country were infected with tuberculosis. Was the Government going to try to bring about an increase in the consumption of liquid milk by the children of the workers of this country when he knew that the effect must mean an increase in the percentage of the distribution of milk which was not free from tuberculosis? He thought that some of the measures proposed for cleaning up the herds were good and he welcomed the change in the grading of milk. The proposal to pay premiums for pure milk was also a very good preliminary measure. He knew that a system of this kind had resulted in an enormous reduction in the number of bacilli per cubic centimetre and an improvement in the fat content. He was not unaware of the immense value of the drinking of raw liquid milk, and even of skimmed milk, by school-children. These were good things, but the milk must be pure. He regarded this Bill as a trick measure which he did not believe would do what the nation wanted. There was no sign that it would be T.T. milk that would be supplied to school-children. The only way that they would get a move on in getting pure milk in adequate quantities for the nation was by preventing the sale of non-tested milk by retailers.

Lord CRANWORTH said that from time to time the medical profession had urged the necessity for cleaning up the milk-supply. He would be happier if, when they criticised the uncleanly methods of British farmers, they also turned attention occasionally to the people overseas as well. An analysis of the skimmed sweetened and unsweetened milk imported from abroad had shown that practically the whole value of that compound lay in the sugar. For hundreds of thousands of children in the poorer classes that was the only form of milk which they got. In all probability the harm done to those children by drinking that condensed sweetened milk was far greater than if they drank the dirtiest milk produced on any British farm. Probably 80 per cent. of the cows that were reactors could be discovered by careful and regular clinical examinations. In a year or two those reactors and dangerous cows would become fewer and fewer until in all probability they became almost non-existent. The scheme now proposed for accredited herds was an eminently desirable one, for the herds to be accredited would have to pass through a minimum number of clinical examinations a year, but it was still more important that all herds should be subject to periodical clinical examination. There was also the question of the reliability of the test. Anyone who had herds would know how desperately unreliable these tests were at present. If they were going to increase very largely the veterinary staff it was hardly likely that the standard of veterinary skill would increase in the way necessary to make the test as reliable as it should be. In the case of bovine tuberculosis science had made as great strides as in other branches of medicine. A book had just been published called "Spahlinger *contra* Tuberculosis." It contained a host of reliable names giving evidence, lay, medical, and veterinary. It described Spahlinger's experiments in Switzerland and in Norfolk which were successful. Finally, the Government of Northern Ireland were so impressed by these tests that they decided to hold a Government inquiry. On December 17th, 1932, they published a report of an official demonstration made in Belfast which showed that 100 per cent. of the calves immunised by Spahlinger's vaccine had triumphantly resisted an infection of tuberculosis which proved fatal to non-vaccinated calves in a few weeks. To the medical man there might very well be reasons which proved that all that was stated in this book was not true, but it was full of names of the very highest repute, and if one-quarter of what was said was true this was a thing that ought not to be lightly set aside.

Viscount ASTOR said that it was obvious that a certain amount of milk was unsatisfactory and even dangerous, but it was very easy to emphasise the danger to children by over-emphasising that particular point. It was probable that of the cows which reacted to the tuberculin test only 22 per cent. gave tuberculous milk, and that of the whole tuberculous population only 5 per cent. suffered from bovine tuberculosis. The deaths from non-pulmonary tuberculosis, and on the whole that was the infantile death-rate, in 1911 was 14,600. Last year the deaths had dropped to 5400, or about one-third of what they had been. That indicated a very decided improvement in the quality of the milk available for children. If they were to make a herd tubercle-free it was absolutely vital that they should have a reliable test, otherwise they got reinfection in the herds. Unless they had skilled veterinary surgeons of experience to carry out this very difficult work they would not get similar results. In regard to which subjects he was recently an examiner for the diploma of the English Conjoint Board. He was an able draughtsman, and in conversation would often pull out paper and pencil and illustrate his views on the points under discussion. He was interested in old books, especially those relating to botany. He held many important posts in connexion with the British Medical Association, and enjoyed well-merited esteem for much all-round work, public and professional.

DAVID ROSS, M.D. Aberd.

Dr. David Ross, who died at his house in Kingsland-road, London, on July 4th, received his early education in Aberdeen, studied medicine in the University of the City, and also at St. Bartholomew's Hospital, London, and graduated M.B., C.M. Aberd. in 1894. In 1898 he obtained the M.D. Aberd. with highest honours, and shortly afterwards settled down to practice in the north of London, where he enjoyed a wide reputation for efficiency and public spirit. He did valuable service for many years for the British Medical Association, being at different times a member of the Representative Body and of the Council. He was for a time honorary medical officer to the Metropolitan Hospital, he served as President of the Hunterian Society, and was vice-chairman of the National Service Medical Board of the City of London. He was also for a period examiner in materia medica at the University of Aberdeen. Dr. David Ross was a very able man, well read and considerably travelled, and his death has been felt as a loss by a large circle.

CHARLES JOSEPH HEATH, F.R.C.S. Eng.

The death occurred on July 13th at his house in York-terrace, Regent's Park, London, of Mr. C. J. Heath, who was principally known in connexion with methods devised for the remedy of chronic suppuration of the ear, and the restoration of hearing.

Charles Joseph Heath was born in 1856, and educated at Totnes Grammar School, proceeding for his medical training to St. Bartholomew's Hospital. He was a successful student from the beginning, winning the Treasurer's Prize in practical anatomy for first year students, and the Foster Prize awarded for similar proficiency to more advanced pupils; the result was an appointment as prosector at the Royal College of Surgeons of England. He took the diploma of M.R.C.S. in 1884, and the final Fellowship in 1886. He was then, for a period, house surgeon at the Preston Royal Infirmary, but continued his interest in structural anatomy, and decided to specialise in otology, as providing an outlet for his skill in dissection. He returned to London, and was appointed assistant surgeon to the Central London Throat, Nose and Ear Hospital, and later surgeon to the Golden-square Throat, Nose and Ear Hospital, his services being also requisitioned by the Metropolitan Asylums Board.

The procedures which he devised for the cure of chronic suppuration of the middle ear, without removal of the drum or ossicles, were described in a paper read before the Otological Society in 1904. Accompanying the reading of this paper he showed several patients who had been operated upon by his modification of the radical mastoid operation. This paper was itself a sequel to one read before a local medical society previously in which he had endeavoured to demonstrate the good results of his operative measures. In the interval he had performed his operation a hundred times with such a measure of success that he was, he said, convinced that it, possibly with slight modifications, would ultimately be adopted as a means of restoring hearing to a large number of persons afflicted with suppurative disease. But although his views led to close discussion he made few disciples among the leaders of his specialty. In 1907 he described in our columns ten cases where the cure of chronic suppuration of the middle ear had followed the employment of his methods, neither the drum nor ossicles having been removed, and the hearing remaining good. He continued to report on the favourable results of further series of patients, and at a debate before the British Laryngological, Rhinological and Otological Association in the same year he met with more support than he had previously experienced, though words of caution were uttered with regard to the dangers that his variation in the radical mastoid operation might bring about. He had a large practice as an aural surgeon, and spoke at congresses and wrote in the transactions of societies and elsewhere, with conviction, on his subject. During the war he was attached as aural surgeon to one of the military hospitals, and his mechanical aptitude was here displayed in modifications of the gas helmet, while he also put forward an altered design for army boots.

Heath was a keen sportsman, and a member of the Wild Birds Advisory Committee of the Home Office. He was devoted to both fishing and shooting, and in connexion with the latter sport it is characteristic of him that he invented a wild-fowling gun. He was a widower, his wife, who died in 1930, being the daughter of Colonel J. J. Wilson, he is survived by two daughters.

ALEXANDER THEODORE BRAND, M.D.

The death of Dr. Alexander Theodore Brand at the advanced age of 81, which took place at Great Driffield, Yorks, will be deeply regretted by a large circle of patients and personal friends. To one of these we owe the following biographical note.

"For some years Alexander Brand was engaged in business in Aberdeen, but he always had a great desire to study medicine, and in 1877 he began his course at the University of Aberdeen, being a good many years older than his fellow students, and the writer of these lines, who began his curriculum in the following session, admired at the time, and has ever since from a fuller experience of life continued to admire, the good fellowship and understanding which always existed between him and his juniors. This was a state of affairs which was to the credit not only of Brand but of the youngsters who worked alongside of him. He qualified as M.B., C.M. in 1881 and proceeded to the degree of M.D. in 1884. Some time was spent in the London and Vienna schools and then he became associated with the late Dr. Eames in his practice at Great Driffield, and when Dr. Eames left the district he carried on the practice for some time alone and later in association with his relative Dr. J. R. Keith. He was not a frequent writer, but he made certain communications in support of the infective nature of cancer on which he held strong views.

When Brand was in business in Aberdeen he was a keen volunteer and held commissioned rank in the 1st Volunteer Battalion of the Gordon Highlanders. Later he became Major in the R.A.M.C. and was O.C. 2nd Field Ambulance East Yorks Volunteers, and retired with the rank of surgeon major (V.D.). He was much interested in the work of the St. John Ambulance Association and he was an officer in the Order of St. John. For many years he was the dical officer of the Driffield and District Poor-law irmary. He was a man of fine presence, great charm manner, courteous, kind, and absolutely straight- ward in his dealings."

SIR JAMES KINGSTON FOWLER.—The accidental utilation of a sentence in the obituary notice which appeared last week of Sir James Kingston Fowler must be corrected. The notice states that not many of his colleagues on the Beit Foundation knew him personally; the exact reverse was the case, and the sentence should have run "not many of the other Fellows knew him personally." We much regret the error.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Milk Bill and the Tuberculin Test

IN the House of Lords on Thursday, July 12th, Earl DE LA WARR, Parliamentary Secretary to the Ministry of Agriculture, moved the second reading of the Milk Bill which has already passed through the House of Commons. He said that the Government would feel that in this Bill they were putting before their Lordships a really balanced policy for the milk industry. It could be divided into three parts. The first was an attempt to save the industry and stave off ruin by putting a bottom into the market. That scheme would cost something over £1,500,000 per annum. That payment would operate over a period of two years, and after that period if prices had risen to a certain height these payments would have to be repaid to the Exchequer. The second and third parts of the policy constituted an attempt to increase the production of milk in this country. The first method of doing that was by cleaning up the herds from the fell disease of tuberculosis, which was, unfortunately, too common among cows, and the second method was a scheme of milk publicity, of spending £500,000 a year for the next two years very largely on increasing the supply of milk in schools for school-children.

Lord MARLEY said that Earl De La Warr had said that they must improve the quality of milk and increase the consumption and he proposed to spend public money in doing those two things simultaneously. Was he going to use public money to advertise immediately by an increased consumption of rotten milk which was now being distributed or was he going to wait until the milk was really good before he advertised by an increase in the consumption by school-children? The noble lord should have said that the quality of milk in this country was probably less good than in any modern civilised country. According to the Report of the Committee on Cattle Diseases, at least 40 per cent. of the cows in dairy herds in this country were infected with tuberculosis. Was the Government going to try to bring about an increase in the consumption of liquid milk by the children of the workers of this country when he knew that the effect must mean an increase in the percentage of the distribution of milk which was not free from tuberculosis? He thought that some of the measures proposed for cleaning up the herds were good and he welcomed the change in the grading of milk. The proposal to pay premiums for pure milk was also a very good preliminary measure. He knew that a system of this kind had resulted in an enormous reduction in the number of bacilli per cubic centimetre and an improvement in the fat content. He was not unaware of the immense value of the drinking of raw liquid milk, and even of skimmed milk, by school-children. These were good things, but the milk must be pure. He regarded this Bill as a trick measure which he did not believe would do what the nation wanted. There was no sign that it would be T.T. milk that would be supplied to school-children. The only way that they would get a move on in getting pure milk in adequate quantities for the nation was by preventing the sale of non-tested milk by retailers.

Lord CRANWORTH said that from time to time the medical profession had urged the necessity for cleaning up the milk-supply. He would be happier if, when they criticised the uncleanly methods of British farmers, they also turned attention occasionally to the people overseas as well. An analysis of the skimmed sweetened and unsweetened milk imported from abroad had shown that practically the whole value of that compound lay in the sugar. For hundreds of thousands of children in the poorer classes that was the only form of milk which they got. In all probability the harm done to those children by drinking that condensed sweetened milk was far greater than if they drank the dirtiest milk produced on any British farm. Probably 80 per cent. of the cows that were reactors could be discovered by careful and regular clinical examinations. In a year or two those reactors and dangerous cows would become fewer and fewer until in all probability they became almost non-existent. The scheme now proposed for accredited herds was an eminently desirable one, for the herds to be accredited would have to pass through a minimum number of clinical examinations a year, but it was still more important that all herds should be subject to periodical clinical examination. There was also the question of the reliability of the test. Anyone who had herds would know how desperately unreliable these tests were at present. If they were going to increase very largely the veterinary staff it was hardly likely that the standard of veterinary skill would increase in the way necessary to make the test as reliable as it should be. In the case of bovine tuberculosis science had made as great strides as in other branches of medicine. A book had just been published called "Spahlinger *contra* Tuberculosis." It contained a host of reliable names giving evidence, lay, medical, and veterinary. It described Spahlinger's experiments in Switzerland and in Norfolk which were successful. Finally, the Government of Northern Ireland were so impressed by these tests that they decided to hold a Government inquiry. On December 17th, 1932, they published a report of an official demonstration made in Belfast which showed that 100 per cent. of the calves immunised by Spahlinger's vaccine had triumphantly resisted an infection of tuberculosis which proved fatal to non-vaccinated calves in a few weeks. To the medical man there might very well be reasons which proved that all that was stated in this book was not true, but it was full of names of the very highest repute, and if one-quarter of what was said was true this was a thing that ought not to be lightly set aside.

Viscount ASTOR said that it was obvious that a certain amount of milk was unsatisfactory and even dangerous, but it was very easy to emphasise the danger to children by over-emphasising that particular point. It was probable that of the cows which reacted to the tuberculin test only 22 per cent. gave tuberculous milk, and that of the whole tuberculous population only 5 per cent. suffered from bovine tuberculosis. The deaths from non-pulmonary tuberculosis, and on the whole that was the infantile death-rate, in 1911 was 14,600. Last year the deaths had dropped to 5400, or about one-third of what they had been. That indicated a very decided improvement in the quality of the milk available for children. If they were to make a herd tubercle-free it was absolutely vital that they should have a reliable test, otherwise they got reinfection in the herds. Unless they had skilled veterinary surgeons of experience to carry out this very difficult work they would not get similar results. In regard to the tuberculin used, it was necessary that its potency or strength should be adequate, and that the strength of all tuberculin used for the test should be the same. The Tuberculin Committee of the Medical Research Council had emphasised in a memorandum the importance of satisfactory tuberculin. He suggested that either the Government should standardise tuberculin, or if that was impossible owing to administrative difficulties, then the Government should restrict the use of tuberculin for licensed herds to specified brands of known and adequate potency. If they did that he was certain that the process of cleaning up the herds would be accelerated and they would induce more farmers to test their herds and produce greater confidence among the public. He also urged that there should be more frequent testing than twice a year.

After further debate,

Earl DE LA WARR said that for the purpose of the final test of herds only standardised tuberculin would be used. Further it was hoped that in future when legislation made possible the control of certain therapeutic substances, that tuberculin would be one of the first substances to be dealt with. With regard to the scheme for milk in schools, such milk would be approved by the medical officer of health, and where the medical officer of health was not the same man as the school medical officer then it would also have to be approved by the school medical officer. He was quite sure therefore that Lord Marley would regret having thrown such an unfounded charge at the head of the Government as that they were going to force dirty milk into the schools.

Lord MARLEY said that he was very glad that that would not be the case.

The Bill was read a second time.

Poor Law (Scotland) Bill

The Poor Law (Scotland) Bill was also read a second time.

Royal Assent

On July 11th the Royal Assent was given in the House of Lords by Royal Commission to a number of Acts, including the Finance Act and the Prince of Wales's Hospital, Plymouth, Act.

Domiciliary Nursing Services

On July 10th, in the House of Commons, Sir G. HURST asked leave to bring in a Bill to enable local and county authorities to provide for domiciliary nursing services, to appoint and pay nurses, to provide accommodation for them, and to make reasonable subscriptions or donations to voluntary associations.

Leave was granted and the Bill was read a first time.

In the House of Commons on July 16th the Ministry of Health Provisional Order Confirmation (South Middlesex and Richmond Joint Hospital District) Bill was read the third time.

Road Accidents and Medical Treatment

In the House of Lords on Tuesday, July 17th, the Road Traffic Bill was considered in Committee. The Earl of ONSLOW was in the chair.

On clause 1 (which imposes a general speed limit of 30 miles an hour on built-up areas.)

Viscount CECIL moved an amendment to leave out the words in the clause which provided that the speed limit should not operate between midnight and 5 A.M.

The Earl of PLYMOUTH, speaking for the Government, said that out of 7000 fatal accidents on the roads in 1933, less than 160 occurred between midnight and 5 A.M. Less than half of these, 65, were in built-up areas. Of 3000 pedestrians killed in 1933, over 2700 were between the ages of 15 and 55, and most of such people would not be about on the roads between midnight and 5 A.M. There was also the difficulty of enforcing a speed limit during those hours.

The amendment was strongly supported by several noble lords and was agreed to.

Viscount BERTIE OF THAME moved a new clause providing that a person charged with driving a car when under the influence of drink or drugs should be subject, if so required, to be examined and tested with respect to his condition as soon as might be after his request by a registered medical practitioner selected by the police, and should have the right to be examined and tested also, if he so desired, by a doctor or other person selected by himself. He said that if the clause was accepted everybody would know that if they were charged with being drunk or under the influence of drugs while in charge of a motor-car they would be subjected to a medical examination, whether they consented or not.

The Earl of PLYMOUTH said that there was something in the proposal that where drunkenness was an element in an offence a person charged should not be able to prevent an examination which might help to ascertain his real condition. The clause, however, would go too far in some cases and not far enough in others. In practice it was often impossible for the police to decide until after a medical examination whether a charge ought properly to be brought or not, and a person might be ill and not under the influence of drugs or drink. The clause was too wide in that it subjected to risk of punishment a person who objected to conform to the test suggested. In practice the noble lord's proposal was not required. In any case where a person's condition was a matter of doubt, it was the well-established practice of the police to call in a doctor to examine him, and if he wished also to be examined by a doctor nominated by himself he was allowed to do so and the police had instructions to that effect. The truth was that medical examination did not lend itself to compulsion backed by legal sanction.

The new clause was withdrawn.

The Earl of PLYMOUTH, replying to a question by Earl HOWE with regard to the possibility of prohibiting the use of motor horns at certain hours at night, said that the Minister of Transport had had the matter under consideration. It was the Minister's intention to proceed cautiously and experimentally, and to select certain limited areas in which to prohibit the use of motor horns during certain hours of the night.

On clause 13 (payments and insurance in respect of emergency treatment of injuries arising from the use of motor vehicles on roads.

Lord SANDHURST moved to leave out the word "motor" so as to make the clause applicable to accidents caused by other forms of vehicles. He said they were doing their best to reduce accidents on the roads, and one of the most important things in that connexion was to create a spirit of good-will and helpfulness on the roads. If they were going to start a spirit of class destruction and encourage class war on the roads they would not get the spirit of helpfulness which was necessary. By the inclusion of the word "motor" in the Bill they were stigmatising one set of people. This would not do the medical profession a good service. At present doctors were only being paid for emergency treatment in respect of one-third of the road accidents. He saw no logical reason for that. If the doctors were going to collect thousands of fees at 12s. 6d. in respect of such treatment they should collect for all the accidents and not only for two-thirds of them. He agreed that they should do something to see that doctors were paid for their services, but the only way to do it was to see that every vehicle user shared the responsibility. That would encourage more vehicle users who were not motorists to be a little more careful.

The Earl of PLYMOUTH said he could not accept the amendment.

The amendment was negatived.

Lord SOMERLEYTON moved an amendment providing that the clause should apply not only to accidents on the roads but also to accidents in places to which the public had a right of access.

ADDRESSES AND ORIGINAL ARTICLES

CLIMATE AND HEALTH*

By S. WATSON SMITH, M.D., F.R.C.P. Edin.,
M.R.C.P. Lond.
HONORARY PHYSICIAN, ROYAL VICTORIA AND WEST HANTS HOSPITAL, BOURNEMOUTH

[Dr. Watson Smith commenced by extending a cordial welcome to Bournemouth to the members of the Association and their accompanying visitors in the name of the medical men of the town and neighbourhood and of the civic authorities of the borough. He recalled that it was 43 years since the annual meeting of the British Medical Association was held in Bournemouth, when Dr. John Robert Thomson, whose name, he said, was impressed upon the benevolent institutions of Bournemouth, occupied the presidential chair, that occasion being the 59th annual meeting of the Association.] With regard to the subject of the present address, the President said that he would begin by defining his subject and outlining the

History of Medical Climatology

In talking of climate we shall not try now to define the term in the Johnsonian fashion as "a space upon the surface of the earth, measured from the equator to the polar circles"; or in the sense used by Sir Thomas Browne, when he wrote (1643) that he was born in the eighth climate; or again, in the popular meaning, as a region differing from another by reason of the temperature of the air. We shall define it in a broader sense, the meaning of the word, modified by time and necessity, indicating all the solar and terrestrial factors and influences which affect animal and vegetable life, including sunlight, atmospheric temperature, humidity and pressure movement of the air, and prevailing winds—the factors which make our climate what it is; and, whilst including airs, also embracing waters and places. My remarks will also refer to the history of medical climatology and hydrology generally, and to the advisability of more frequent use of British spas and health resorts. In the choice of this subject it seemed to me that Bournemouth—fair as it is and so handsomely endowed by nature with beauty, grace, and charm—was a fitting place from which to speak. Alone of its kind and in the front rank of coastal health resorts, this area can claim to have restored health to invalids without number, and to have afforded rest and recreation for the many. Here, in Shakespeare's words, "The clymat's delicate, the ayre most sweet."

THE INFLUENCE OF GREECE

It is generally believed that, in the dawn of civilisation, from the Middle East and from the shores of the Mediterranean, migrations of a people, mainly pastoral, took place in consequence of drought, a changed climate causing insufficient sustenance for tribes and flocks; and that thus knowledge spread eastward to China (2300 B.C.)—where even to-day a superstitious belief survives in the malign effects of climatic influences (Fung-Shui, literally wind and water)—to Libya and Egypt, whence to Greece, whither many Egyptian ideas made their way.

In Greece medical knowledge and practice flourished, chiefly in the Cnidos Peninsula and in Rhodes, the "rose-covered" island of the Ægean, where climate and physical influences seem to have been specially studied by the Greek philosophers; and in Cos and at Epidaurus, where the cult of Asklepios first appears. At these places health temples were founded—originally sacred shrines controlled by priests, their sites being chosen, not only from proximity to wells or hot springs, but also with a view to climatic salubrity. At these temples patients would drink the waters and bathe; the sick would flock thither to be treated by the presiding priests, just as cure and relief are now sought by pilgrimage to a holy well. The extent to which such "spas" were used is shown by the provision for entertainment at the health temple of Epidaurus of an open-air theatre capable of accommodating 12,000 and of a stadium for 20,000.

Pausanias, in his "Description of Greece," mentions that whilst visiting Epidaurus he met a traveller from Sidon, who declared his opinion that Apollo was the sunshine and Asklepios, his son, the fresh air. His worship as the god of healing was widely spread among the Greeks. His powers included even that of raising the dead. In his honour temples were built at many places, the most notable, that of Epidaurus, becoming the traditional seat of the cultus of the god, originally probably a form of sun worship.

A salutary belief underlay the religion of Asklepios, that the maladies of the soul could be reached through the subtle gateways of the body; that, in the words of Walter Pater, "the body became but an handmaid of the soul." Thus the Greeks strove for perfect physical development, esteemed even above learning, their artists and philosophers employing their rare talents in the production of beauty and the search for truth. This idea of a *select* humanity was revealed in the Stoic plan of a world of the wise only, and in later Christian times found its expression in the conception of the Church as the only pathway to salvation for the human race.

The earliest surviving treatise on climatology is the chapter "Of Airs, Waters and Places" in the works of the immortal Hippocrates (460–370 B.C.), Father of Medicine, in which he deals with many questions of importance in public hygiene, giving numerous incidental references to the effects of weather and climate, winds, seasons, and localities. At this period Greek art and learning were at their zenith, instructing, edifying, and refining the world as they still ought to be doing. Hippocrates showed an extraordinary grasp of matters relating not only to climate and its causes, but also to the art of medicine; so much so that he founded a system of physic which embraced the results of actual observation in place of the superstition and hypothesis till then obtaining, and dominated medical practice for many centuries.

ROMAN DEVELOPMENTS AND MEDIÆVAL INACTION

In Rome, Scipio Africanus (died 129 B.C.) was one of the first to order the construction of baths. Later, in A.D. 21, thermæ were opened by Vipsanius Agrippa, son-in-law of Augustus and grandfather of Caligula. It became customary to build a large bath over a natural hot spring, attaching to it several smaller baths. The neighbourhood of these became fashionable watering-places. Authors like Petronius and Martial throw much light on Roman bathing. The latter, taking note of the smallest details, describes a visit to the public and private baths, each of which had its own regular customers. He watches the masseurs manipulating their patients, and a wily thief awaiting the right opportunity of pilfering from a bather's robe. It was usual for special bathing times to be allotted according to the rank and social status of the bather. Occasionally a bath would be used in common by the sexes; but such mixed bathing was forbidden by Trajan and by his successor Hadrian. In the reign of Justinian (A.D. 527–565), builder of St. Sophia, partitions were put up to separate the Byzantine sexes. During the Roman occupation of Britain spas and health resorts were founded, some of which, like Bath, "remain unto this day." London also had its medicinal wells and baths, the latter being early established there by the Romans.

---

* Presidential Address (abstract), delivered on July 24th before the 102nd annual meeting of the British Medical Association held at Bournemouth.

In the obscure ages which succeeded the fall of the Western Empire the use of mineral springs dwindled, but after the Crusades (A.D. 1096–1272) warm baths again became fashionable, some associated with saints developing into centres of pilgrimage. During the fifteenth century the Greeks fled from fallen Constantinople, leaving their baths behind them for its conquerors, but taking with them into Italy their literature and learning, so that in the sixteenth century Hippocrates's work was again the example to follow in the practice of medicine.

FROM HARVEY UNTIL TO-DAY

At length the immortal Harvey, by his work *De Motu Cordis* (1628), a record of investigation made by the experimental method, overturned the whole theory of the ancients, founding principles and the practice of physic on the scientific basis whereon they now stand. Thomas Sydenham, Father of Clinical Medicine, "a rare man," laid great stress upon the seasonal variations of disease and the relation of disease-distribution to latitude.

At the end of the eighteenth and the beginning of the nineteenth century the climatic dangers of travel were demonstrated by the failure and destruction of the two expeditions into Africa of Mungo Park, himself a surgeon (see his *Travels*). But since the last few years of the nineteenth century a great improvement has taken place in tropical hygiene and sanitation. Many deadly climatic diseases are now known to be of parasitic origin, the constant warm climates of tropical regions rendering them the best breeding-ground for the organisms causing such diseases. Due to the direct effect of climate upon the parasites or their human or extra-human hosts, these diseases are fortunately absent from temperate and cold latitudes.

The second half of the nineteenth century was the scientific age, noted for its advances in medicine and surgery. Consequently, in the present century, many of the worst areas of the earth, where so many of our fellow-countrymen have been "climate-beaten" in the past, have been rendered wholesome and habitable for all races of mankind by pioneer work, done often under great risk to health and life, by colleagues of the profession. Such results have been brought about by the application of methods evolved by the original work of men like Patrick Manson, David Bruce, Ronald Ross, Andrew Balfour, and countless others, true pioneers of Empire, many of whom had passed on, forgotten by their own times, unhonoured and unsung; they constitute a splendid record of self-sacrificing labour on behalf of the civilisation and well-being of mankind, and afford a demonstration of that spirit and genius, the proud heritage and hall-mark of the profession of medicine.

In these days we seem to live in an age of transition, when each man's scientific knowledge and opportunities are expanding and increasing well-nigh beyond belief. Yet we find the same riddles presenting themselves for solution as in previous ages, merely changed in their scientific features. There must always be a demand for proof: a constant testing of our assumptions, investigations, and conclusions, to prove them true or false, and accordingly to receive or abandon them. The doctrines of science, many of which are now admittedly beyond dispute, at first confined to the scattered few, have been gradually gaining general acceptance. By the processes of trial and search for error they are constantly being clarified and corrected. Science, indeed, by its revelation of the established order of things, shares common ground with religion.

[Dr. Watson Smith, alluding to the belief that climate is the most influential of the natural causes controlling the destinies of mankind, pointed out that the chief factor governing climate was isolation, and continued:—]

Airs and Waters

An excessive exposure to light rays, whether natural or artificial, entail fatigue and exhaustion, but it also produces early degeneration of the skin, such as may be seen in sailors. The external ears, the lower half of the face, and the backs of the hands degenerate so as to exhibit a skin become thin, atrophied, and pigmented, upon which are grafted warty growths which, later, may assume a malignant form. Because of immediate and remote risks of over-radiation, caution should be advised in the use of the sun bath and of artificial light baths. But, properly and prudently used, sunlight is of inestimable value. From the point of view of the man of business alone it has been proved that daylight and industrial efficiency are directly proportional, the one measuring the other. Such efficiency may also be encouraged by the creation of a so-called artificial climate, mechanically controlled as to temperature, humidity, and movement of air, promoting ventilation indoors, which should be applicable with advantage to the modern hospital or school, and to places of business or amusement. But the sun is the ruler of all climates and determines temperature, the lessened or increased humidity of which has been used as a practical means of classifying climate as bracing and tonic, or sedative and relaxing: the former including busy places providing entertainment and excitement suitable for those needing bracing-up, an escape from routine business, and change from sedentary work; the latter qualifying resorts favourable to rest and tranquillity, beneficial in nervous complaints, such as insomnia, in high blood pressure, or in disorders of the heart and circulation. There are, however, in the British Isles, all gradations between the two extremes. The term "relaxing," in reference to climate, I use in no derogatory sense such as enervating, but as synonymous with "sedative," indicating the quiet and repose desirable for the relief of these and other conditions of ill-health, and the maladies of old age, compelling a slowing-down of the pace, and encouraging restful days and nights and a reduced metabolic rate.

THE ILL-INSTRUCTED PUBLIC

The ignorance of the majority as to the climate, and so the health resort, best suited for them is notorious. A careful study of an invalid's general state of health and mental traits should be made before recommending the suitable place. Often a climate with frequent but moderate variations will prove beneficial, the more so if combined with a regular rhythm of rest, sleep, open-air exercise, and a properly supervised and dispensed diet; beautiful surroundings, changes of scene and of manner of life, all helping to encourage the invalid. As our knowledge of applied climatology increases it will be found to be more and more of value as a factor in the successful treatment and diminution, or even elimination, of disease, the results of which, under differing climatic conditions in various parts of the world, and especially of the British Isles and Empire, will thus be tabulated and mapped out.

Waters and baths are to be looked upon as factors accessory to climate, over which they may have a dominating therapeutic influence. Spas frequently specialise in the treatment of particular ailments, and should be classified not only according to type of climate but also upon their therapeutic indications. Mineral waters have their pharmacological action by virtue of their water-content, and of the various contained chemical and physical properties. Some have radio-activity, a property of high value, which is being increasingly utilised in treatment; a quality, however, so evanescent as to be speedily dissipated on exposure, so that such water must be used immediately when drawn.

Although from a medical standpoint doubt has been cast upon the value of the chemical properties of spa waters, this doubt has been dispelled with a more exact knowledge of biochemistry, which has led to a correct interpretation of their action, and so of their medical use. Up to the middle of the nineteenth century, when medical climatology again came into prominence, spa practice was purely empirical. Now every resort with a claim to therapeutic value should develop its own resources along scientific lines. For, in the words of Fortescue Fox, "Each spa has its own individuality," which should be fostered and guided aright by utility in treatment and by a reasonable limitation of its reputed curative value, so that a wise choice may be made by a physician for the benefit of his patient. A family resemblance among spas as to their medical value should not too lightly be taken for granted, for how often has it not been repeated that we do not treat diseases, but those who suffer from them; and so with spas as places of treatment, the aim of which should be to enhance and profit by the climatic and other advantages of the place.

THE CHARACTERISTICS OF SPA WATERS: BRITISH CLAIMS

[Dr. Watson Smith then outlined the main characteristics of spa waters, dwelling on their biochemical action, their tonic advantages, and—which he termed a feature of cardinal importance—their replenary effects, or the results obtained by the regular replenishment of the circulation by a normal intake of water. He went on to point out that with the urbanisation of the country insufficient rest was a fruitful source of premature collapse, so that sedative sojourns or changes of climate formed a valuable escape from the nervous strains of modern life. He pointed out that while south coast resorts might bring relief to those suffering from essential arterial supertension, insomnia, or debility consequent on nervous stress and strain, the British Isles also abounded, on the east and west coasts, with bracing climates. He continued:—]

With advancing age, when "the years draw nigh, when thou shalt say, I have no pleasure in them," it is wise to take an interest in Nature, whose simple ways thus acquire a charm for us hitherto, maybe, unnoticed, and the lovely villages and backwaters of the countryside "bring the soul nearer to the divine source of all being." The temperature and changeable climate of the British Isles have in the past bred a vigorous, hardy race, able to face life in almost any part of the world. This must be considered one of the chief underlying causes of the formation and successful growth of the British Empire, fostered and encouraged by the great Queen in the nineteenth century. At the present time the fashionable rest cure appears to be the sea-cruise holiday in the sun, offering the completest rest possible for the healthy man, his whole mental outlook changing, as the waves carry him away for many days from shore conditions. For the healthy and vigorous nothing can be better; but for the invalid the discomforts of rough weather and sea-sickness, with the possibility of being "cabin'd, cribb'd, confined" in consequence, render such cruises of very questionable benefit.

Britain, being a most favoured land as to spas and health resorts, it is now generally understood in the profession that there is seldom, if ever, medical necessity to winter abroad, unless it be to obtain by altitude, or by dry or sea air, a suitable climate for the tuberculous or asthmatic. Moreover, the discomforts of travel, change of language and food, absence of home comforts and friends (to say nothing of the less satisfactory sanitary arrangements prevailing on the continent), can be more easily faced, nay, converted into sources of amusement, by the young, high-spirited, and healthy, than by the elderly or invalid. On the other hand, there is no doubt that continental or foreign travel, giving a complete change, may often be beneficial in cases of mental strain and nervous trouble; producing, as it does, a detachment from insular home prejudices, a broadening of outlook by unfamiliar scenes, manners, and customs, and encouraging an interchange of visits and courtesies from country to country.

Directions for Development

Whilst the duty, too often neglected, of increasing the amenities and preserving the beauties of health resorts and spas must primarily belong to public authorities, the scientific, sane, and right guidance of their development should naturally be the part of an educated medical profession. Both locally and generally the whole subject ought to be surveyed, reviewed, and tabulated. Such places are a national asset; the increase of their value to the national health should therefore be the concern of the State and of public bodies to support and encourage. The medical men on the spot, with their experience and local knowledge, must inevitably be the advisers as to type of patient and disease to be benefited and relieved by the resources available at the place in question. . . .

Medicinal springs and baths should be under a public control, ensuring regular chemical analyses, purity, ease of access to the waters, and the circulation of accurate information available alike for rich and poor, for doctor or patient, detailing such accessory matters as climate, environment, endowment of the place with natural beauties, and its mental and bodily advantages: in a word, the individuality of the neighbourhood, *genius loci*. At these health resorts the public is demanding additional methods of treatment, including all manner of baths. Besides providing medicinal, these resorts should offer a wide range of electrical, physical, and other external accessory means and methods for the re-education of body functions and of structures such as joints and muscles. So that an up-to-date watering-place wishing to prosper will do well not to be deficient in these respects or in available advice as to diet and mode of life best suited to the particular climate or malady.

The average hotel or boarding-house, no doubt, prefers catering for the healthy rather than for the sick. But the comfort and well-being of the latter are essential for the fair reputation or continued prosperity of any place calling itself a *health* resort, and could be fostered and maintained by a varied improvement of facilities for attendance and for the provision of various special diets. An admirable plan would include the provision in hotels catering for invalids of one or more State-registered nurses, responsible to the patient and his medical adviser, and to them only; an invalid annexe would be another device for the attraction and lodging of visitors not fitted for the ordinary daily routine of the healthy. Patients would be ambulatory or convalescent, not confined to bed or in need of any special medical attention.

There is much need for an increase at health resorts in the number of convalescent homes, suited to the means of all sections of the community, not excluding the over-burdened upper and middle classes. Such institutions, municipally or privately owned, administered perhaps under health insurance schemes, might be, so to speak, territorial or regional, used near a patient's home in finer months, or in the south or west in winter. Their cost would amply be repaid by increased efficiency in work of all descriptions, and by gradual elimination of the later stages of such maladies as those of the rheumatic or fibrositic type, which cause so much disablement with loss of time and wages. Our health resorts are in need of necessary, but sympathetic, reorganisation and improvement, much of which could be effected by a healthy rivalry in catering for the requirements of the jaded and sick, and by competition in the provision of the things that matter, among which are those of the mind. . . . Our health resorts should be equipped for mental as well as for corporal benefit. The provision of libraries, art galleries, and museums is as necessary, if not so patently urgent, as that of convalescent homes and baths; a day may come when the healing art will include advice as to suitable studies in art, science, and literature as mental tonics.

The advantages of our health resorts are not infrequently lost to the sick through doubt, indifference, or scepticism as to their real value; by bad and selfish building development; by destruction of natural beauty; by ugly as opposed to reasonable and beautiful forms of advertisement; by too much noise; or by a cost of living which it should be the aim of all sensible governments to reduce. Signs are not wanting, however, of good efforts to lay the foundations of a better state of things by a well-directed campaign of education as to the great advantages of British spas and resorts, not only to ourselves in these islands and to our kinsfolk abroad, but also to our neighbours on the continents of Europe and America.

ST. THOMAS'S HOSPITAL SAMARITAN FUND.—Last year 1505 patients were sent to convalescent homes by this fund at a cost of £3452, towards which they contributed £1116; the Samaritan Fund found £606. Surgical instruments were provided for 2392 patients, at a cost of £2213, towards which the patients contributed £1052. Convalescent homes received 946 patients from the wards and 559 from the out-patient and casualty departments.

GLANDULAR FEVER AND INFECTIOUS MONONUCLEOSIS[*]

By H. LETHEBY TIDY, M.D. Oxon., F.R.C.P. Lond.
PHYSICIAN TO ST. THOMAS'S HOSPITAL, LONDON

GLANDULAR fever may be described as an acute infectious disease characterised by fever, enlargement of the lymphatic glands, and changes in the blood, especially lymphocytosis. Pfeiffer gave it the name of *Drüsenfieber*, or glandular fever. Sprunt and Evans, in 1920, used the title "infectious mononucleosis" without recognising the identity of their cases with Pfeiffer's disease.

The discovery of the blood changes has established the existence of glandular fever as an entity, but the outbreaks of the last few years have revealed its extraordinarily protean nature. We shall subsequently divide it into three clinical groups: (1) a glandular type, mainly in children of 5 to 15 years; (2) an anginose type, also known as "monocytic angina"; and (3) a febrile type, mainly in young adults, in which "infective mononucleosis," as described by Sprunt in America, may be included.

Historical

The disease, in the sole form in which it was recognised until the last few years, was first fully described by Emil Pfeiffer in Germany in 1889, under the title of Drüsenfieber. Filatow, a Russian pædiatrist, had given a brief account of it in 1885, but this cannot be compared with Pfeiffer's. The essentials of his description are as follows:—

> "A child of 5 to 8 years of age is taken ill suddenly with fever, malaise and some discomfort in the neck. The glands in the neck, especially at the posterior border of the sterno-mastoid, are obviously swollen and painful. The fauces are somewhat reddened, but there is no exudation and the angina is not so extensive as to account for the high fever. The liver and spleen are palpable. Axillary and inguinal glands are never enlarged. The glands never suppurate and the course is always favourable. The fever lasts up to eight or ten days. The condition is infectious and occurs in epidemics."

Pfeiffer thus recognised that glandular fever was infectious and was a general infection although he overlooked the enlargement of the axillary and inguinal glands. He had no knowledge of any blood changes.

The historical vicissitudes of glandular fever are a matter of some interest. For 30 years after Pfeiffer's article was published discussion was confined entirely to the clinical aspects. As soon as it appeared, however, others recognised that they had seen the same syndrome. In the discussion which followed his communication, Heubner mentioned the occurrence of hæmorrhagic nephritis, and the occasional development of urticaria.

That the axillary and inguinal glands were usually enlarged was first noted by Desplats in 1894. In the same year Hörschelmann described a scarlatiniform eruption, and also the occurrence of severe membranous angina. In 1896 Park West published an account of 96 cases seen in the course of three years in a country district in Ohio. This is the first record of cases in America. The first article on glandular fever in Great Britain was written by Dawson Williams and appeared in THE LANCET in 1897. It was a good account of the disease commonly seen in children.

---

[*] The Lumleian lectures for 1934, delivered to the Royal College of Physicians of London on March 15th and 20th.

By this time the attacks upon glandular fever as an entity had already begun. Neumann, in 1891, published a series of cases under the title of *Akute Idiopathische Halsdrüsenentzündung.* In half of these there was suppuration, and it is clear that this group had no relation to glandular fever. But it was claimed that they proved that glandular fever is only a local pyogenic cervical adenitis. (In point of fact, suppuration almost never occurs in glandular fever.) It was also suggested that it was secondary to rhinopharyngitis, as by Labbé in 1901. Many authors described it as a complication of influenza, amongst others Gallois in 1901, Delcourt in 1905, and Finkelstein and Fischl in Germany as late as 1924. Others ascribed it to intestinal intoxication (Hochsinger, Trautmann).

In 1908 Pfeiffer read a communication on the disease at the Kongress für innerer Medizin. This is his sole article on the subject apart from the original description in 1889. He added nothing of importance. No one discussed it and no notice was taken of it. Glandular fever had indeed been practically dead for some years previously. From 1906 to 1920 the medical journals of the world contain scarcely a score of articles on glandular fever, and few of these are of any interest. Between 1915 and 1920 I cannot find a record of a single paper with this title, although epidemics must have occurred amongst young soldiers in close quarters. (Burnford is the single observer, as far as I am aware, to whom the possibility occurred. In 1918 he suggested that a group of cases with pyrexia and enlarged glands belonged to Pfeiffer's Drüsenfieber.) Its memory was just kept alive by brief descriptions in general text-books on medicine, though not in works on diseases in children or infectious diseases, or on hæmatology, in which indeed at the present time it sometimes finds no place.

So far glandular fever had depended solely on its clinical features. The *hæmatological period* commenced in 1918 to 1920. During several years previously isolated cases of absolute lymphocytosis with recovery had been occasionally published, the recovery often being thought to be a "cure" of leukæmia due to some method of treatment. These recorded cases are few in number, and I have only been able to trace the following previous to 1918: Curschmann, 1906; Türk, 1907; Cabot, 1913; Marchand, 1913; Jackson and Smith, 1915; Hall, 1915; Ireland, Baetjer, and Ruhrah, 1915; and Eason, 1918.

Curschmann's is apparently the first record of a blood count in a case which may be not unreasonably accepted as glandular fever. It was diagnosed as abnormal mumps. The white cells numbered 50,000 per c.mm., and the lymphocytes 78 per cent.

Türk attracted some attention to his case by the dramatic account of his surprise when he met the patient in the street two weeks after giving a hopeless prognosis. He expressed the opinion that the condition "could not be regarded as more than a sublymphæmic lymphomatosis."

Cabot and Marchand unfortunately believed that the blood changes were due to sepsis, and this possible result of sepsis was accepted for some years, though now disbelieved.

Hall's communication marked an advance. He was the first author to become aware of previous articles, and he recognised that his case was closely similar to those described by Türk, Cabot, and Marchand. He consequently concluded that they were examples of some clinical entity still unknown at that time.

It may be noted that Breinl, Priestley, and Fielding in 1914 published in Australia an account of a local disease under the title Endemic Glandular Fever in the Mossman District, which has many resemblances to Pfeiffer's disease. Somewhat similar cases are described by Haberfeld of Vienna, which were seen by him whilst in Brazil. He attributed the infection to tick bites.

The first series of cases in which an absolute lymphocytosis was present was published by Deussing in 1918, under the title "Ueber diphtherieähnlicher Anginen mit lymphatischer Reaktion" (angina resembling diphtheria with a lymphatic reaction). His 12 cases were from an infectious diseases hospital and were examples of what subsequently became known as "monocytic angina."

He noted the enlarged glands, but accepted them as part of the reaction. His description of the mononuclear cells closely resembles modern descriptions of those in other types of glandular fever. He makes no mention of glandular fever.

He believed that the angina was of ordinary non-diphtheritic type and that the lymphocytosis was the result of a constitutional tendency to "lymphatic reaction" on the part of each individual patient, and did not recognise that he was dealing with the results of a special disease.

A similar paper was published in 1920 by Jagic and Schiffner on the lymphatic reaction in aphthous stomatitis.

In November, 1920, Sprunt and Evans, in America, published the first article in which the existence of an infectious lymphocytosis was clearly stated. They noted throat symptoms, the general glandular enlargement, the palpable spleen, and the invariably favourable prognosis. Their description of the types of cells fairly represents the appearances. They named the condition "infectious mononucleosis." This was an original nomenclature, which had never previously been used. They made no reference to Pfeiffer's glandular fever; indeed, for some time subsequently the identity of the two types was denied in America.

In March, 1921, Bloedorn and Houghton, also in America, published four similar cases under the title "acute benign lymphoblastosis." They did not recognise its infectious nature.

In March, 1921, Morley and I recorded the first case diagnosed as glandular fever in which the presence of a lymphocytosis was recognised. The patient was a boy aged 8 years, who had a typical attack of glandular fever. The blood showed a leucocyte count of 15,000 per c.mm., with 75 per cent. of lymphocytes. On reading Sprunt and Evans's article we were satisfied that the two groups were of the same origin.

Morse, in October, 1921, published two adult cases resembling Sprunt and Evans's, under the title of "glandular fever," and considered that the two conditions were identical. Longcope, in 1922, published 10 cases as "infectious mononucleosis (glandular fever)," and in 1923 Downey and McKinlay recorded 9 under the designation "acute lymphadenosis." Both papers contain good descriptions of the types of cells present. Indeed, Downey's is the classical and best study extant.

By 1925 the identity of the two conditions was accepted in Britain and America, but on the continent the existence of the entity was doubted for many years. During most of the decade 1920 to 1930, German and Austrian authorities were actively engaged in discussing the occurrence of "monocytic angina" and the "lymphatic reaction" without realising that these were cases of glandular fever. In England and America this discussion on monocytic angina has never aroused much interest and the condition has been accepted almost tacitly as a form of glandular fever. There is no appreciable literature on the subject in the English language.

The foreign authorities went astray from the start. They became obsessed with the idea that the development of the lymphocytosis was the result of a constitutional lymphatic tendency in the individual which was called into activity by the angina. They held that the angina was the initial morbid factor and that it did not differ from the angina which would provoke polynucleosis in other individuals. They did not recognise that they were dealing with an infectious disease of which both the angina and the lymphocytosis were a part.

Deussing's article has already been mentioned, but Schultz's communication on Monozytenangina in 1922, to the Congress for Internal Medicine, first attracted general attention to the subject. It was based on five cases (published by Baader) which were similar to Deussing's and were admitted as diphtheria to an infectious diseases hospital. Baader noted the unusually long duration of the angina and of the fever, also the generalised glandular enlargement and the palpable spleen. The membranous angina cannot be distinguished from diphtheria by its appearance. Schultz held that the cells were monocytes and not lymphocytes and that the blood changes were due to a constitutional lymphatic reaction. Though Schultz's views were widely accepted, lengthy discussions as to the nature of the cells took place (Baar, Hopmann, Preuss).

Criticisms of Schultz's views began to appear in German literature, first on the ground that the cells were lymphocytes, secondly because similar blood changes were reported in cases with much slighter faucial symptoms, and thirdly on the ground that the blood changes were symptoms of a "morbus" and not a constitutional abnormal reaction (Brogsitter, Kwasniewski and Henning, Schmidheiny). In 1927 Schultz with Mirisch agreed haltingly that the cells were lymphocytes, but refused to accept the identity of cases with and without angina in spite of the identity of the hæmatological changes and of the enlargement of the glands and spleen. They upheld the constitutional lymphatic reaction in their type.

The differentiation of monocytic angina from glandular fever and the theory of a constitutional lymphatic reaction thus continued and articles on the same lines followed up to 1929 from Hartwich, Lenhartz, Hrabowski, and Feer, and indeed are still appearing. As Nyfeldt says, "monocytic angina nearly pushed out glandular fever."

The argument that monocytic angina is glandular fever was put forward on the continent by Glanzmann in his monograph on Glandular Fever in 1930, by Nyfeldt in 1932, and by Lehndorff and Schwarz in various articles and in their monograph in 1932. The evidence for the identity of monocytic angina and glandular fever is as follows:—

(1) In epidemics of glandular fever, cases occur with and without angina of all grades, and between the two groups no difference can be found in the blood changes, the glandular swelling, and the enlargement of the spleen.

(2) The cases with membranous angina cannot be distinguished from monocytic angina.

(3) Similar changes in the mononuclear cell are found only in glandular fever and monocytic angina (except possibly in rubella), so far as is at present known.

(4) Monocytic angina differs from other forms of angina in (a) the long prodromal period; (b) the long duration of the angina and fever; (c) the general glandular enlargement; (d) the frequency of recrudescences.

It may now be accepted that monocytic angina is a type of glandular fever. It will be described clinically as the anginose type.

FEBRILE TYPE: THE ENGLISH EPIDEMIC OF 1930

During the years 1920–24 glandular fever must have been prevalent throughout this country. Epidemics occurred in many schools. Between 1925 and 1928 it was rare.

In 1930 there was an extensive epidemic in England, which differed widely from those previously recognised. It was characterised by especially attacking adults, by the prolonged and often severe pyrexia, by the occurrence of an eruption often indistinguishable from typhoid, and by the late onset of the glandular enlargement, often mild in degree, and of the lymphocytosis. At the beginning of May attention was drawn to the epidemic (Tidy); further evidence then quickly appeared from Krestin, Cantor, Evans and Robb, Balme, Loewy, and Hall. Cantor suggested that glandular fever of this type had three stages: (1) stage of onset, with pyrexia and malaise; (2) stage of eruption, from the fourth to the seventh or tenth day; and (3) stage of glandular enlargement, from the tenth day onwards. There is no doubt that this is correct, and expresses briefly the characters of this febrile type of glandular fever.

Parkes Weber and Rolleston especially called attention to the transient positive Wassermann reaction. The presence of an absolute lymphocytosis was noted by all observers. It develops in the third stage with the glandular enlargement.

By the autumn of 1930 the general clinical features of the outbreak were fairly clear. It was extensive over the south of England and extended to the north, but its unusual characters led to frequent errors of diagnosis, especially of influenza, typhoid, and other exanthemata. In October, 1931, a discussion of glandular fever was held at the Royal Society of Medicine, which was practically devoted to this epidemic. Series of cases were reported from Reading by Mills, and from Birmingham by Williams, as well as from London. There is little other literature on this outbreak or this type.

There can be no doubt that this is a type of glandular fever. Its course appears to represent the full development of glandular fever with a prodromal period, a stage of eruption, and a stage of glandular enlargement. Other types and varieties arise from certain phases of the full course being exaggerated and others being absent. It was practically confined to adults in 1930, but cases at younger ages are now known. There are only scanty records of previous epidemics of this type. Botschkowsky in 1900 in Russia, and Spencer in 1926 in America, appear to have seen epidemics. A single instance occurs among Longcope's cases published in 1922. Steinfield and Goldberg recorded a case in 1926. It is difficult to find other satisfactory examples.

One may wonder in what guise glandular fever will next make its appearance.

Ætiology

Distribution. — The disease has been recorded throughout Europe except in the extreme south, in North America, China, Australia, and the Falkland Islands. No case is reported from South Africa. With regard to the tropics, the only records are an epidemic in Trinidad described by Cochrane, and two cases in Manila described by Hasselmann. There is no satisfactory case from India.

Age-incidence.—Probably no age is immune to any type. It has been recorded at 4 months by Glanzmann, and at 70 years by Moir, but it is rare over 40 years. The glandular type is commonest between the ages of 6 and 15 years. In adults it tends to be very mild. The febrile type is most common and typical between the ages of 15 and 25 or 30 years. Infectious mononucleosis is a mild "febrile type," and occurs mainly at the same ages. The anginose type is most common between 10 and 25 years; it also occurs in young children, but is rarely of the same severity.

The incubation period appears to lie usually between

5 and 15 days. I have seen fairly definite examples at 5 and at 12 days.

The degree of infectivity is not high. Single cases will often occur in a family and no other child become infected. On the other hand, susceptibility appears to be almost universal. When two or three cases develop in a school and there is an opportunity for mass infection, it frequently happens that all the other children become infected. Droplet infection may be the mode of transmission. It is probable that the disease is infectious only in its early stages. Thus it is clear that the anginose type is practically non-contagious, the infectivity having already passed.

The duration of infectivity cannot be estimated from evidence at present available. As a working rule I would suggest isolation for one week after the temperature has become normal and the main mass of the glands has subsided, and in the absence of any faucial inflammation.

The duration of the infection in the subject is a different question. Recrudescences and recurrences are proof that it may linger for many weeks or months. There is no evidence as to its infectivity in such recurrences.

Sporadic cases have been thought to differ from epidemic cases in their greater severity, more marked blood changes, and lower degree of infectivity. On careful consideration I agree with Glanzmann that there is no difference between sporadic and epidemic cases.

Clinical Manifestations

When Pfeiffer first described glandular fever it appeared to be a simple entity, but it is now known that its manifestations are protean. Lehndorff and Schwarz describe two groups: (*a*) Pfeiffer's type, glandular enlargement prominent; and (*b*) anginose type, faucial changes prominent. They were unacquainted with the prolonged febrile type.

The essential features of glandular fever may be stated as: (1) fever, (2) glandular enlargement, (3) faucial affections, and (4) changes in the blood—i.e., lymphocytosis. The predominance of one feature separates different groups, but no "blood" group is recognised, and glandular fever can be considered in three main groups: (1) glandular or Pfeiffer's type, (2) anginose type (monocytic angina), (3) febrile type. It must be borne in mind that these are groups of the same disease, and consequently all intermediate forms occur.

GLANDULAR OR PFEIFFER'S TYPE

Age and sex.—The majority of cases occur between the ages of 6 and 15 years, but no age is immune.

Prodromal period.—There is commonly a prodromal period before the glandular enlargement of one to four days, usually one or two. It is rarely as long as six days, but possibly may even exceed this. It may appear to be completely absent.

The onset is usually fairly acute. Headache is often complained of and there are the usual features of malaise.

Faucial symptoms.—There is usually complaint of sore-throat at the onset, but on examination there is little to be seen. There may be some general reddening of the fauces, and one or both tonsils may be prominent and red, but without exudation. Occasionally there is some follicular tonsillitis. Pfeiffer's observation that the degree of glandular enlargement was out of proportion to the faucial changes still holds good in this type.

Fever.—The temperature is moderately raised during the prodromal period; it may reach 101° or even 103°. There is practically always pyrexia when the glands enlarge, the degree roughly corresponding to the acuteness of the onset and the size of the glands. The temperature generally falls rapidly as the glands diminish in size after three or four days, and usually reaches normal in the second week. With recurrence of glandular swelling the temperature tends to rise again.

Constitutional symptoms are slight. The patient does not appear to be seriously ill, and there is no anæmia. There is no eruption. The pulse and respiration are not unduly rapid for the temperature. Vomiting occasionally occurs and the bowels are apt to be constipated. Abdominal pain is not infrequent, but usually not at the onset. There may be a slight cough. Epistaxis is not uncommon and may be severe.

Enlargement of lymphatic glands is the predominating feature. All or any group of glands may be enlarged, but the cervical glands are pre-eminently affected. It is rare for other groups to be enlarged in their absence or to the same extent.

Cervical glands.—The enlargement of the cervical glands is commonly recognised within the first three days. The increase in size often takes place with great rapidity and a visible mass may develop in a few hours. The glands may, however, take two or three days to reach their maximum. A definite mass is usually unilateral; on the opposite side some smaller glands are palpable, and subsequently these may enlarge further. It is frequently stated that the left side is far more commonly affected than the right, but in my own experience I am unable to find any marked difference. The glands most characteristically enlarged are deep to the sternomastoid, about the middle of its length and somewhat below the level of the angle of the jaw. They are discrete and movable, and have a firm elastic consistency on palpation.

Any of the glands in the neck may be affected. Œdema of the skin and tissues is very rare. The pre-auricular, submaxillary, and submental lymphatic glands also are occasionally enlarged. The occipital glands are seldom palpable in this type. The degree of pain and tenderness is variable, but it is rare, though not unknown, for it to be severe. In younger children it may be completely absent. Torticollis has been observed several times, but only lasts a few days. Spasm of the muscles at the back of the neck may also occur and cause suspicion of meningitis.

Axillary glands.—These become palpable probably in 80 per cent. of cases, but nearly always after the cervical glands. They rarely exceed the size of hazel-nuts. A definite mass occasionally develops.

Inguinal glands.—These are less often enlarged than the axillary. There may be a chain of considerable size and extent. The epitrochlear glands are not infrequently palpable.

Parotid and salivary glands.—It is disputed whether or not the parotid and other salivary glands are ever involved. This is a question of some interest as glandular fever has been frequently diagnosed as "aberrant mumps." Very few instances are recorded (Hörschelmann in 1894, Haas in 1912), but Glanzmann states that he is certain that he saw six cases in the large outbreak in Berne. Personally I have never seen a case in which the parotid became affected. I have been in doubt several times between the diagnosis of glandular fever, mumps, and sepsis. The after records show that in such cases the condition is almost always sepsis.

Thoracic and mediastinal glands.—Pfeiffer in his original article noted the occurrence of cough which he attributed to pressure of retrotracheal glands, and von Starck in 1890 observed that the cough in glandular fever may have a convulsive character suggestive of whooping-cough. Several cases have been published giving evidence of pressure on the bronchi (Glanzmann, Tidy). This has been confirmed radiographically by Buttenwieser, Longcope, and Nelken.

Mesenteric glands.—The development of palpable masses with abdominal disturbances is often recorded, as by Park West. I have several times felt definite

The foreign authorities went astray from the start. They became obsessed with the idea that the development of the lymphocytosis was the result of a constitutional lymphatic tendency in the individual which was called into activity by the angina. They held that the angina was the initial morbid factor and that it did not differ from the angina which would provoke polynucleosis in other individuals. They did not recognise that they were dealing with an infectious disease of which both the angina and the lymphocytosis were a part.

Deussing's article has already been mentioned, but Schultz's communication on Monozytenangina in 1922, to the Congress for Internal Medicine, first attracted general attention to the subject. It was based on five cases (published by Baader) which were similar to Deussing's and were admitted as diphtheria to an infectious diseases hospital. Baader noted the unusually long duration of the angina and of the fever, also the generalised glandular enlargement and the palpable spleen. The membranous angina cannot be distinguished from diphtheria by its appearance. Schultz held that the cells were monocytes and not lymphocytes and that the blood changes were due to a constitutional lymphatic reaction. Though Schultz's views were widely accepted, lengthy discussions as to the nature of the cells took place (Baar, Hopmann, Preuss).

Criticisms of Schultz's views began to appear in German literature, first on the ground that the cells were lymphocytes, secondly because similar blood changes were reported in cases with much slighter faucial symptoms, and thirdly on the ground that the blood changes were symptoms of a "morbus" and not a constitutional abnormal reaction (Brogsitter, Kwasniewski and Henning, Schmidheiny). In 1927 Schultz with Mirisch agreed haltingly that the cells were lymphocytes, but refused to accept the identity of cases with and without angina in spite of the identity of the hæmatological changes and of the enlargement of the glands and spleen. They upheld the constitutional lymphatic reaction in their type.

The differentiation of monocytic angina from glandular fever and the theory of a constitutional lymphatic reaction thus continued and articles on the same lines followed up to 1929 from Hartwich, Lenhartz, Hrabowski, and Feer, and indeed are still appearing. As Nyfeldt says, "monocytic angina nearly pushed out glandular fever."

The argument that monocytic angina is glandular fever was put forward on the continent by Glanzmann in his monograph on Glandular Fever in 1930, by Nyfeldt in 1932, and by Lehndorff and Schwarz in various articles and in their monograph in 1932. The evidence for the identity of monocytic angina and glandular fever is as follows :—

(1) In epidemics of glandular fever, cases occur with and without angina of all grades, and *between the two groups no difference can be found in* the blood changes, the glandular swelling, and the enlargement of the spleen.

(2) The cases with membranous angina cannot be distinguished from monocytic angina.

(3) Similar changes in the mononuclear cell are found only in glandular fever and monocytic angina (except possibly in rubella), so far as is at present known.

(4) Monocytic angina differs from other forms of angina in (*a*) the long prodromal period ; (*b*) the long duration of the angina and fever ; (*c*) the general *glandular enlargement* ; (*d*) the frequency of recrudescences.

It may now be accepted that monocytic angina is a type of glandular fever. It will be described clinically as the anginose type.

FEBRILE TYPE: THE ENGLISH EPIDEMIC OF 1930

During the years 1920–24 glandular fever must have been prevalent throughout this country. Epidemics occurred in many schools. Between 1925 and 1928 it was rare.

In 1930 there was an extensive epidemic in England, which differed widely from those previously recognised. It was characterised by especially attacking adults, by the prolonged and often severe pyrexia, by the occurrence of an eruption often indistinguishable from typhoid, and by the late onset of the glandular enlargement, often mild in degree, and of the lymphocytosis. At the beginning of May attention was drawn to the epidemic (Tidy); further evidence then quickly appeared from Krestin, Cantor, Evans and Robb, Balme, Loewy, and Hall. Cantor suggested that glandular fever of this type had three stages: (1) stage of onset, with pyrexia and malaise; (2) *stage of eruption, from the fourth to the seventh or* tenth day ; and (3) stage of glandular enlargement, from the tenth day onwards. There is no doubt that this is correct, and expresses briefly the characters of this febrile type of glandular fever.

Parkes Weber and Rolleston especially called attention to the transient positive Wassermann reaction. The presence of an absolute lymphocytosis was noted by all observers. It develops in the third stage with the glandular enlargement.

By the autumn of 1930 the general clinical features of the outbreak were fairly clear. It was extensive over the south of England and extended to the north, but its unusual characters led to frequent errors of diagnosis, especially of influenza, typhoid, and other exanthemata. In October, 1931, a discussion of glandular fever was held at the Royal Society of Medicine, which was practically devoted to this epidemic. Series of cases were reported from Reading by Mills, and from Birmingham by Williams, as well as from London. There is little other literature on this outbreak or this type.

There can be no doubt that this is a type of glandular fever. Its course appears to represent the full development of glandular fever with a prodromal period, a stage of eruption, and a stage of glandular *enlargement. Other types and varieties arise from* certain phases of the full course being exaggerated and others being absent. It was practically confined to adults in 1930, but cases at younger ages are now known. There are only scanty records of previous epidemics of this type. Botschkowsky in 1900 in Russia, and Spencer in 1926 in America, appear to have seen epidemics. *A single instance occurs* among Longcope's cases published in 1922. Steinfield and Goldberg recorded a case in 1926. It is difficult to find other satisfactory examples.

One may wonder in what guise glandular fever will next make its appearance.

Ætiology

Distribution. — The disease has been recorded throughout Europe except in the extreme south, in North America, China, Australia, and the Falkland Islands. No case is reported from South Africa. With regard to the tropics, the only records are an epidemic in Trinidad *described by Cochrane*, and two cases in Manila described by Hasselmann. There is no satisfactory case from India.

Age-incidence.—Probably no age is immune to any type. It has been recorded at 4 months by Glanzmann, and at 70 years by Moir, but it is rare over 40 years. The glandular type is commonest between the ages of 6 and 15 years. *In adults it tends to be very mild.* The febrile type is most common and typical between the ages of 15 and 25 or 30 years. Infectious mononucleosis is a *mild "febrile type,"* and occurs *mainly* at the same ages. The anginose type is most common between 10 and 25 years ; it also occurs in young children, but is rarely of the same severity.

The incubation period appears to lie usually between

5 and 15 days. I have seen fairly definite examples at 5 and at 12 days.

The degree of infectivity is not high. Single cases will often occur in a family and no other child become infected. On the other hand, susceptibility appears to be almost universal. When two or three cases develop in a school and there is an opportunity for mass infection, it frequently happens that all the other children become infected. Droplet infection may be the mode of transmission. It is probable that the disease is infectious only in its early stages. Thus it is clear that the anginose type is practically non-contagious, the infectivity having already passed.

The duration of infectivity cannot be estimated from evidence at present available. As a working rule I would suggest isolation for one week after the temperature has become normal and the main mass of the glands has subsided, and in the absence of any faucial inflammation.

The duration of the infection in the subject is a different question. Recrudescences and recurrences are proof that it may linger for many weeks or months. There is no evidence as to its infectivity in such recurrences.

Sporadic cases have been thought to differ from epidemic cases in their greater severity, more marked blood changes, and lower degree of infectivity. On careful consideration I agree with Glanzmann that there is no difference between sporadic and epidemic cases.

Clinical Manifestations

When Pfeiffer first described glandular fever it appeared to be a simple entity, but it is now known that its manifestations are protean. Lehndorff and Schwarz describe two groups: (*a*) Pfeiffer's type, glandular enlargement prominent; and (*b*) anginose type, faucial changes prominent. They were unacquainted with the prolonged febrile type.

The essential features of glandular fever may be stated as: (1) fever, (2) glandular enlargement, (3) faucial affections, and (4) changes in the blood—i.e., lymphocytosis. The predominance of one feature separates different groups, but no "blood" group is recognised, and glandular fever can be considered in three main groups: (1) glandular or Pfeiffer's type, (2) anginose type (monocytic angina), (3) febrile type. It must be borne in mind that these are groups of the same disease, and consequently all intermediate forms occur.

GLANDULAR OR PFEIFFER'S TYPE

Age and sex.—The majority of cases occur between the ages of 6 and 15 years, but no age is immune.

Prodromal period.—There is commonly a prodromal period before the glandular enlargement of one to four days, usually one or two. It is rarely as long as six days, but possibly may even exceed this. It may appear to be completely absent.

The onset is usually fairly acute. Headache is often complained of and there are the usual features of malaise.

Faucial symptoms.—There is usually complaint of sore-throat at the onset, but on examination there is little to be seen. There may be some general reddening of the fauces, and one or both tonsils may be prominent and red, but without exudation. Occasionally there is some follicular tonsillitis. Pfeiffer's observation that the degree of glandular enlargement was out of proportion to the faucial changes still holds good in this type.

Fever.—The temperature is moderately raised during the prodromal period; it may reach 101° or even 103°. There is practically always pyrexia when the glands enlarge, the degree roughly corresponding to the acuteness of the onset and the size of the glands. The temperature generally falls rapidly as the glands diminish in size after three or four days, and usually reaches normal in the second week. With recurrence of glandular swelling the temperature tends to rise again.

Constitutional symptoms are slight. The patient does not appear to be seriously ill, and there is no anæmia. There is no eruption. The pulse and respiration are not unduly rapid for the temperature. Vomiting occasionally occurs and the bowels are apt to be constipated. Abdominal pain is not infrequent, but usually not at the onset. There may be a slight cough. Epistaxis is not uncommon and may be severe.

Enlargement of lymphatic glands is the predominating feature. All or any group of glands may be enlarged, but the cervical glands are pre-eminently affected. It is rare for other groups to be enlarged in their absence or to the same extent.

Cervical glands.—The enlargement of the cervical glands is commonly recognised within the first three days. The increase in size often takes place with great rapidity and a visible mass may develop in a few hours. The glands may, however, take two or three days to reach their maximum. A definite mass is usually unilateral; on the opposite side some smaller glands are palpable, and subsequently these may enlarge further. It is frequently stated that the left side is far more commonly affected than the right, but in my own experience I am unable to find any marked difference. The glands most characteristically enlarged are deep to the sternomastoid, about the middle of its length and somewhat below the level of the angle of the jaw. They are discrete and movable, and have a firm elastic consistency on palpation.

Any of the glands in the neck may be affected. Œdema of the skin and tissues is very rare. The pre-auricular, submaxillary, and submental lymphatic glands also are occasionally enlarged. The occipital glands are seldom palpable in this type. The degree of pain and tenderness is variable, but it is rare, though not unknown, for it to be severe. In younger children it may be completely absent. Torticollis has been observed several times, but only lasts a few days. Spasm of the muscles at the back of the neck may also occur and cause suspicion of meningitis.

Axillary glands.—These become palpable probably in 80 per cent. of cases, but nearly always after the cervical glands. They rarely exceed the size of hazel-nuts. A definite mass occasionally develops.

Inguinal glands.—These are less often enlarged than the axillary. There may be a chain of considerable size and extent. The epitrochlear glands are not infrequently palpable.

Parotid and salivary glands.—It is disputed whether or not the parotid and other salivary glands are ever involved. This is a question of some interest as glandular fever has been frequently diagnosed as "aberrant mumps." Very few instances are recorded (Hörschelmann in 1894, Haas in 1912), but Glanzmann states that he is certain that he saw six cases in the large outbreak in Berne. Personally I have never seen a case in which the parotid became affected. I have been in doubt several times between the diagnosis of glandular fever, mumps, and sepsis. The after records show that in such cases the condition is almost always sepsis.

Thoracic and mediastinal glands.—Pfeiffer in his original article noted the occurrence of cough which he attributed to pressure of retrotracheal glands, and von Starck in 1890 observed that the cough in glandular fever may have a convulsive character suggestive of whooping-cough. Several cases have been published giving evidence of pressure on the bronchi (Glanzmann, Tidy). This has been confirmed radiographically by Buttenwieser, Longcope, and Nelken.

Mesenteric glands.—The development of palpable masses with abdominal disturbances is often recorded, as by Park West. I have several times felt definite

The foreign authorities went astray from the start. *They became obsessed with the idea that the development* of the lymphocytosis was the result of a constitutional lymphatic tendency in the individual which was called into activity by the angina. (4) Monocytic angina differs from other forms of angina in (*a*) the long prodromal period; (*b*) the long duration of the angina and fever; (*c*) the general glandular enlargement; (*d*) the frequency of recrudescences.

It may now be accepted that monocytic angina is a type of glandular fever. It will be described clinically as the anginose type.

FEBRILE TYPE: THE ENGLISH EPIDEMIC OF 1930

During the years 1920–24 glandular fever must have been prevalent throughout this country. Epidemics occurred in many schools. Between 1925 and 1928 it was rare.

In 1930 there was an extensive epidemic in England, which differed widely from those previously recognised. It was characterised by especially attacking adults, by the prolonged and often severe pyrexia, by the occurrence of an eruption often indistinguishable from typhoid, and by the late onset of the glandular enlargement, often mild in degree, and of the lymphocytosis. At the beginning of May attention was drawn to the epidemic (Tidy); further evidence then quickly appeared from Krestin, Cantor, Evans and Robb, Balme, Loewy, and Hall. Cantor suggested that glandular fever of this type had three stages: (1) stage of onset, with pyrexia and malaise; (2) stage of eruption, from the fourth to the seventh or tenth day; and (3) stage of glandular enlargement, from the tenth day onwards. There is no doubt that this is correct, and expresses briefly the characters of this febrile type of glandular fever.

Parkes Weber and Rolleston especially called attention to the transient positive Wassermann reaction. The presence of an absolute lymphocytosis was noted by all observers. It develops in the third stage with the glandular enlargement.

By the autumn of 1930 the general clinical features of the outbreak were fairly clear. It was extensive over the south of England and extended to the north, but its unusual characters led to frequent errors of diagnosis, especially of influenza, typhoid, and other exanthemata. In October, 1931, a discussion of glandular fever was held at the Royal Society of Medicine, which was practically devoted to this epidemic. Series of cases were reported from Reading by Mills, and from Birmingham by Williams, as well as from London. There is little other literature on this outbreak or this type.

There can be no doubt that this is a type of glandular fever. Its course appears to represent the full development of glandular fever with a prodromal period, a stage of eruption, and a stage of glandular enlargement. Other types and varieties arise from certain phases of the full course being exaggerated and others being absent. It was practically confined to adults in 1930, but cases at younger ages are now known. There are only scanty records of previous epidemics of this type. Botschkowsky in 1900 in Russia, and Spencer in 1926 in America, appear to have seen epidemics. A single instance occurs among Longcope's cases published in 1922. Steinfield and Goldberg recorded a case in 1926. It is difficult to find other satisfactory examples.

One may wonder in what guise glandular fever will next make its appearance.

Ætiology

Distribution. — The disease has been recorded throughout Europe except in the extreme south, in North America, China, Australia, and the Falkland Islands. No case is reported from South Africa. With regard to the tropics, the only records are an epidemic in Trinidad described by Cochrane, and two cases in Manila described by Hasselmann. There is no satisfactory case from India.

Age-incidence.—Probably no age is immune to any type. It has been recorded at 4 months by Glanzmann, and at 70 years by Moir, but it is rare over 40 years. The glandular type is commonest between the ages of 6 and 15 years. In adults it tends to be very mild. The febrile type is most common and typical between the ages of 15 and 25 or 30 years. Infectious mononucleosis is a mild "febrile type," and occurs mainly at the same ages. The anginose type is most common between 10 and 25 years; it also occurs in young children, but is rarely of the same severity.

The incubation period appears to lie usually between

5 and 15 days. I have seen fairly definite examples at 5 and at 12 days.

The degree of infectivity is not high. Single cases will often occur in a family and no other child become infected. On the other hand, susceptibility appears to be almost universal. When two or three cases develop in a school and there is an opportunity for mass infection, it frequently happens that all the other children become infected. Droplet infection may be the mode of transmission. It is probable that the disease is infectious only in its early stages. Thus it is clear that the anginose type is practically non-contagious, the infectivity having already passed.

The duration of infectivity cannot be estimated from evidence at present available. As a working rule I would suggest isolation for one week after the temperature has become normal and the main mass of the glands has subsided, and in the absence of any faucial inflammation.

The duration of the infection in the subject is a different question. Recrudescences and recurrences are proof that it may linger for many weeks or months. There is no evidence as to its infectivity in such recurrences.

Sporadic cases have been thought to differ from epidemic cases in their greater severity, more marked blood changes, and lower degree of infectivity. On careful consideration I agree with Glanzmann that there is no difference between sporadic and epidemic cases.

Clinical Manifestations

When Pfeiffer first described glandular fever it appeared to be a simple entity, but it is now known that its manifestations are protean. Lehndorff and Schwarz describe two groups: (*a*) Pfeiffer's type, glandular enlargement prominent; and (*b*) anginose type, faucial changes prominent. They were unacquainted with the prolonged febrile type.

The essential features of glandular fever may be stated as: (1) fever, (2) glandular enlargement, (3) faucial affections, and (4) changes in the blood—i.e., lymphocytosis. The predominance of one feature separates different groups, but no "blood" group is recognised, and glandular fever can be considered in three main groups: (1) glandular or Pfeiffer's type, (2) anginose type (monocytic angina), (3) febrile type. It must be borne in mind that these are groups of the same disease, and consequently all intermediate forms occur.

GLANDULAR OR PFEIFFER'S TYPE

Age and sex.—The majority of cases occur between the ages of 6 and 15 years, but no age is immune.

Prodromal period.—There is commonly a prodromal period before the glandular enlargement of one to four days, usually one or two. It is rarely as long as six days, but possibly may even exceed this. It may appear to be completely absent.

The onset is usually fairly acute. Headache is often complained of and there are the usual features of malaise.

Faucial symptoms.—There is usually complaint of sore-throat at the onset, but on examination there is little to be seen. There may be some general reddening of the fauces, and one or both tonsils may be prominent and red, but without exudation. Occasionally there is some follicular tonsillitis. Pfeiffer's observation that the degree of glandular enlargement was out of proportion to the faucial changes still holds good in this type.

Fever.—The temperature is moderately raised during the prodromal period; it may reach 101° or even 103°. There is practically always pyrexia when the glands enlarge, the degree roughly corresponding to the acuteness of the onset and the size of the glands. The temperature generally falls rapidly as the glands diminish in size after three or four days, and usually reaches normal in the second week. With recurrence of glandular swelling the temperature tends to rise again.

Constitutional symptoms are slight. The patient does not appear to be seriously ill, and there is no anæmia. There is no eruption. The pulse and respiration are not unduly rapid for the temperature. Vomiting occasionally occurs and the bowels are apt to be constipated. Abdominal pain is not infrequent, but usually not at the onset. There may be a slight cough. Epistaxis is not uncommon and may be severe.

Enlargement of lymphatic glands is the predominating feature. All or any group of glands may be enlarged, but the cervical glands are pre-eminently affected. It is rare for other groups to be enlarged in their absence or to the same extent.

Cervical glands.—The enlargement of the cervical glands is commonly recognised within the first three days. The increase in size often takes place with great rapidity and a visible mass may develop in a few hours. The glands may, however, take two or three days to reach their maximum. A definite mass is usually unilateral; on the opposite side some smaller glands are palpable, and subsequently these may enlarge further. It is frequently stated that the left side is far more commonly affected than the right, but in my own experience I am unable to find any marked difference. The glands most characteristically enlarged are deep to the sternomastoid, about the middle of its length and somewhat below the level of the angle of the jaw. They are discrete and movable, and have a firm elastic consistency on palpation.

Any of the glands in the neck may be affected. Œdema of the skin and tissues is very rare. The pre-auricular, submaxillary, and submental lymphatic glands also are occasionally enlarged. The occipital glands are seldom palpable in this type. The degree of pain and tenderness is variable, but it is rare, though not unknown, for it to be severe. In younger children it may be completely absent. Torticollis has been observed several times, but only lasts a few days. Spasm of the muscles at the back of the neck may also occur and cause suspicion of meningitis.

Axillary glands.—These become palpable probably in 80 per cent. of cases, but nearly always after the cervical glands. They rarely exceed the size of hazel-nuts. A definite mass occasionally develops.

Inguinal glands.—These are less often enlarged than the axillary. There may be a chain of considerable size and extent. The epitrochlear glands are not infrequently palpable.

Parotid and salivary glands.—It is disputed whether or not the parotid and other salivary glands are ever involved. This is a question of some interest as glandular fever has been frequently diagnosed as "aberrant mumps." Very few instances are recorded (Hörschelmann in 1894, Haas in 1912), but Glanzmann states that he is certain that he saw six cases in the large outbreak in Berne. Personally I have never seen a case in which the parotid became affected. I have been in doubt several times between the diagnosis of glandular fever, mumps, and sepsis. The after records show that in such cases the condition is almost always sepsis.

Thoracic and mediastinal glands.—Pfeiffer in his original article noted the occurrence of cough which he attributed to pressure of retrotracheal glands, and von Starck in 1890 observed that the cough in glandular fever may have a convulsive character suggestive of whooping-cough. Several cases have been published giving evidence of pressure on the bronchi (Glanzmann, Tidy). This has been confirmed radiographically by Buttenwieser, Longcope, and Nelken.

Mesenteric glands.—The development of palpable masses with abdominal disturbances is often recorded, as by Park West. I have several times felt definite

The foreign authorities went astray from the start. They became obsessed with the idea that the development of the lymphocytosis was the result of a constitutional lymphatic tendency in the individual which was called into activity by the angina. They held that the angina was the initial morbid factor and that it did not differ from the angina which would provoke polynucleosis in other individuals. They did not recognise that they were dealing with an infectious disease of which both the angina and the lymphocytosis were a part.

Deussing's article has already been mentioned, but Schultz's communication on Monozytenangina in 1922, to the Congress for Internal Medicine, first attracted general attention to the subject. It was based on five cases (published by Baader) which were similar to Deussing's and were admitted as diphtheria to an infectious diseases hospital. Baader noted the unusually long duration of the angina and of the fever, also the generalised glandular enlargement and the palpable spleen. The membranous angina cannot be distinguished from diphtheria by its appearance. Schultz held that the cells were monocytes and not lymphocytes and that the blood changes were due to a constitutional lymphatic reaction. Though Schultz's views were widely accepted, lengthy discussions as to the nature of the cells took place (Baar, Hopmann, Preuss).

Criticisms of Schultz's views began to appear in German literature, first on the ground that the cells were lymphocytes, secondly because similar blood changes were reported in cases with much slighter faucial symptoms, and thirdly on the ground that the blood changes were symptoms of a "morbus" and not a constitutional abnormal reaction (Brogsitter, Kwasniewski and Henning, Schmidheiny). In 1927 Schultz with Mirisch agreed haltingly that the cells were lymphocytes, but refused to accept the identity of cases with and without angina in spite of the identity of the hæmatological changes and of the enlargement of the glands and spleen. They upheld the constitutional lymphatic reaction in their type.

The differentiation of monocytic angina from glandular fever and the theory of a constitutional lymphatic reaction thus continued and articles on the same lines followed up to 1929 from Hartwich, Lenhartz, Hrabowski, and Feer, and indeed are still appearing. As Nyfeldt says, "monocytic angina nearly pushed out glandular fever."

The argument that monocytic angina is glandular fever was put forward on the continent by Glanzmann in his monograph on Glandular Fever in 1930, by Nyfeldt in 1932, and by Lehndorff and Schwarz in various articles and in their monograph in 1932. The evidence for the identity of monocytic angina and glandular fever is as follows :—

(1) In epidemics of glandular fever, cases occur with and without angina of all grades, and between the two groups no difference can be found in the blood changes, the glandular swelling, and the enlargement of the spleen.

(2) The cases with membranous angina cannot be distinguished from monocytic angina.

(3) Similar changes in the mononuclear cell are found only in glandular fever and monocytic angina (except possibly in rubella), so far as is at present known.

(4) Monocytic angina differs from other forms of angina in (*a*) the long prodromal period ; (*b*) the long duration of the angina and fever ; (*c*) the general glandular enlargement : (*d*) the frequency of recrudescences.

It may now be accepted that monocytic angina is a type of glandular fever. It will be described clinically as the anginose type.

FEBRILE TYPE: THE ENGLISH EPIDEMIC OF 1930

During the years 1920–24 glandular fever must have been prevalent throughout this country. Epidemics occurred in many schools. Between 1925 and 1928 it was rare.

In 1930 there was an extensive epidemic in England, which differed widely from those previously recognised. It was characterised by especially attacking adults, by the prolonged and often severe pyrexia, by the occurrence of an eruption often indistinguishable from typhoid, and by the late onset of the glandular enlargement, often mild in degree, and of the lymphocytosis. At the beginning of May attention was drawn to the epidemic (Tidy); further evidence then quickly appeared from Krestin, Cantor, Evans and Robb, Balme, Loewy, and Hall. Cantor suggested that glandular fever of this type had three stages: (1) stage of onset, with pyrexia and malaise; (2) stage of eruption, from the fourth to the seventh or tenth day ; and (3) stage of glandular enlargement, from the tenth day onwards. There is no doubt that this is correct, and expresses briefly the characters of this febrile type of glandular fever.

Parkes Weber and Rolleston especially called attention to the transient positive Wassermann reaction. The presence of an absolute lymphocytosis was noted by all observers. It develops in the third stage with the glandular enlargement.

By the autumn of 1930 the general clinical features of the outbreak were fairly clear. It was extensive over the south of England and extended to the north, but its unusual characters led to frequent errors of diagnosis, especially of influenza, typhoid, and other exanthemata. In October, 1931, a discussion of glandular fever was held at the Royal Society of Medicine, which was practically devoted to this epidemic. Series of cases were reported from Reading by Mills, and from Birmingham by Williams, as well as from London. There is little other literature on this outbreak or this type.

There can be no doubt that this is a type of glandular fever. Its course appears to represent the full development of glandular fever with a prodromal period, a stage of eruption, and a stage of glandular enlargement. Other types and varieties arise from certain phases of the full course being exaggerated and others being absent. It was practically confined to adults in 1930, but cases at younger ages are now known. There are only scanty records of previous epidemics of this type. Botschkowsky in 1900 in Russia, and Spencer in 1926 in America, appear to have seen epidemics. A single instance occurs among Longcope's cases published in 1922. Steinfield and Goldberg recorded a case in 1926. It is difficult to find other satisfactory examples.

One may wonder in what guise glandular fever will next make its appearance.

Ætiology

Distribution. — The disease has been recorded throughout Europe except in the extreme south, in North America, China, Australia, and the Falkland Islands. No case is reported from South Africa. With regard to the tropics, the only records are an epidemic in Trinidad described by Cochrane, and two cases in Manila described by Hasselmann. There is no satisfactory case from India.

Age-incidence.—Probably no age is immune to any type. It has been recorded at 4 months by Glanzmann, and at 70 years by Moir, but it is rare over 40 years. The glandular type is commonest between the ages of 6 and 15 years. In adults it tends to be very mild. The febrile type is most common and typical between the ages of 15 and 25 or 30 years. Infectious mononucleosis is a mild "febrile type," and occurs mainly at the same ages. The anginose type is most common between 10 and 25 years ; it also occurs in young children, but is rarely of the same severity.

The incubation period appears to lie usually between

5 and 15 days. I have seen fairly definite examples at 5 and at 12 days.

The degree of infectivity is not high. Single cases will often occur in a family and no other child become infected. On the other hand, susceptibility appears to be almost universal. When two or three cases develop in a school and there is an opportunity for mass infection, it frequently happens that all the other children become infected. Droplet infection may be the mode of transmission. It is probable that the disease is infectious only in its early stages. Thus it is clear that the anginose type is practically non-contagious, the infectivity having already passed.

The duration of infectivity cannot be estimated from evidence at present available. As a working rule I would suggest isolation for one week after the temperature has become normal and the main mass of the glands has subsided, and in the absence of any faucial inflammation.

The duration of the infection in the subject is a different question. Recrudescences and recurrences are proof that it may linger for many weeks or months. There is no evidence as to its infectivity in such recurrences.

Sporadic cases have been thought to differ from epidemic cases in their greater severity, more marked blood changes, and lower degree of infectivity. On careful consideration I agree with Glanzmann that there is no difference between sporadic and epidemic cases.

Clinical Manifestations

When Pfeiffer first described glandular fever it appeared to be a simple entity, but it is now known that its manifestations are protean. Lehndorff and Schwarz describe two groups: (*a*) Pfeiffer's type, glandular enlargement prominent; and (*b*) anginose type, faucial changes prominent. They were unacquainted with the prolonged febrile type.

The essential features of glandular fever may be stated as: (1) fever, (2) glandular enlargement, (3) faucial affections, and (4) changes in the blood—i.e., lymphocytosis. The predominance of one feature separates different groups, but no "blood" group is recognised, and glandular fever can be considered in three main groups: (1) glandular or Pfeiffer's type, (2) anginose type (monocytic angina), (3) febrile type. It must be borne in mind that these are groups of the same disease, and consequently all intermediate forms occur.

GLANDULAR OR PFEIFFER'S TYPE

Age and sex.—The majority of cases occur between the ages of 6 and 15 years, but no age is immune.

Prodromal period.—There is commonly a prodromal period before the glandular enlargement of one to four days, usually one or two. It is rarely as long as six days, but possibly may even exceed this. It may appear to be completely absent.

The onset is usually fairly acute. Headache is often complained of and there are the usual features of malaise.

Faucial symptoms.—There is usually complaint of sore-throat at the onset, but on examination there is little to be seen. There may be some general reddening of the fauces, and one or both tonsils may be prominent and red, but without exudation. Occasionally there is some follicular tonsillitis. Pfeiffer's observation that the degree of glandular enlargement was out of proportion to the faucial changes still holds good in this type.

Fever.—The temperature is moderately raised during the prodromal period; it may reach 101° or even 103°. There is practically always pyrexia when the glands enlarge, the degree roughly corresponding to the acuteness of the onset and the size of the glands. They were unacquainted with the prolonged febrile type.

The essential features of glandular fever may be stated as: (1) fever, (2) glandular enlargement, (3) faucial affections, and (4) changes in the blood—i.e., lymphocytosis. The predominance of one feature separates different groups, but no "blood" group is recognised, and glandular fever can be considered in three main groups: (1) glandular or Pfeiffer's type, (2) anginose type (monocytic angina), (3) febrile type. It must be borne in mind that these are groups of the same disease, and consequently all intermediate forms occur.

GLANDULAR OR PFEIFFER'S TYPE

Age and sex.—The majority of cases occur between the ages of 6 and 15 years, but no age is immune.

Prodromal period.—There is commonly a prodromal period before the glandular enlargement of one to four days, usually one or two. It is rarely as long as six days, but possibly may even exceed this. It may appear to be completely absent.

The onset is usually fairly acute. Headache is often complained of and there are the usual features of malaise.

Faucial symptoms.—There is usually complaint of sore-throat at the onset, but on examination there is little to be seen. There may be some general reddening of the fauces, and one or both tonsils may be prominent and red, but without exudation. Occasionally there is some follicular tonsillitis. Pfeiffer's observation that the degree of glandular enlargement was out of proportion to the faucial changes still holds good in this type.

Fever.—The temperature is moderately raised during the prodromal period; it may reach 101° or even 103°. There is practically always pyrexia when the glands enlarge, the degree roughly corresponding to the acuteness of the onset and the size of the glands. The temperature generally falls rapidly as the glands diminish in size after three or four days, and usually reaches normal in the second week. With recurrence of glandular swelling the temperature tends to rise again.

Constitutional symptoms are slight. The patient does not appear to be seriously ill, and there is no anæmia. There is no eruption. The pulse and respiration are not unduly rapid for the temperature. Vomiting occasionally occurs and the bowels are apt to be constipated. Abdominal pain is not infrequent, but usually not at the onset. There may be a slight cough. Epistaxis is not uncommon and may be severe.

Enlargement of lymphatic glands is the predominating feature. All or any group of glands may be enlarged, but the cervical glands are pre-eminently affected. It is rare for other groups to be enlarged in their absence or to the same extent.

Cervical glands.—The enlargement of the cervical glands is commonly recognised within the first three days. The increase in size often takes place with great rapidity and a visible mass may develop in a few hours. The glands may, however, take two or three days to reach their maximum. A definite mass is usually unilateral; on the opposite side some smaller glands are palpable, and subsequently these may enlarge further. It is frequently stated that the left side is far more commonly affected than the right, but in my own experience I am unable to find any marked difference. The glands most characteristically enlarged are deep to the sternomastoid, about the middle of its length and somewhat below the level of the angle of the jaw. They are discrete and movable, and have a firm elastic consistency on palpation.

Any of the glands in the neck may be affected. Œdema of the skin and tissues is very rare. The pre-auricular, submaxillary, and submental lymphatic glands also are occasionally enlarged. The occipital glands are seldom palpable in this type. The degree of pain and tenderness is variable, but it is rare, though not unknown, for it to be severe. In younger children it may be completely absent. Torticollis has been observed several times, but only lasts a few days. Spasm of the muscles at the back of the neck may also occur and cause suspicion of meningitis.

Axillary glands.—These become palpable probably in 80 per cent. of cases, but nearly always after the cervical glands. They rarely exceed the size of hazel-nuts. A definite mass occasionally develops.

Inguinal glands.—These are less often enlarged than the axillary. There may be a chain of considerable size and extent. The epitrochlear glands are not infrequently palpable.

Parotid and salivary glands.—It is disputed whether or not the parotid and other salivary glands are ever involved. This is a question of some interest as glandular fever has been frequently diagnosed as "aberrant mumps." Very few instances are recorded (Hörschelmann in 1894, Haas in 1912), but Glanzmann states that he is certain that he saw six cases in the large outbreak in Berne. Personally I have never seen a case in which the parotid became affected. I have been in doubt several times between the diagnosis of glandular fever, mumps, and sepsis. The after records show that in such cases the condition is almost always sepsis.

Thoracic and mediastinal glands.—Pfeiffer in his original article noted the occurrence of cough which he attributed to pressure of retrotracheal glands, and von Starck in 1890 observed that the cough in glandular fever may have a convulsive character suggestive of whooping-cough. Several cases have been published giving evidence of pressure on the bronchi (Glanzmann, Tidy). This has been confirmed radiographically by Buttenwieser, Longcope, and Nelken.

Mesenteric glands.—The development of palpable masses with abdominal disturbances is often recorded, as by Park West. I have several times felt definite

The foreign authorities went astray from the start. They became obsessed with the idea that the development of the lymphocytosis was the result of a constitutional lymphatic tendency in the individual which was called into activity by the angina. They held that the angina was the initial morbid factor and that it did not differ from the angina which would provoke polynucleosis in other individuals. They did not recognise that they were dealing with an infectious disease of which both the angina and the lymphocytosis were a part.

Deussing's article has already been mentioned, but Schultz's communication on Monozytenangina in 1922, to the Congress for Internal Medicine, first attracted general attention to the subject. It was based on five cases (published by Baader) which were similar to Deussing's and were admitted as diphtheria to an infectious diseases hospital. Baader noted the unusually long duration of the angina and of the fever, also the generalised glandular enlargement and the palpable spleen. The membranous angina cannot be distinguished from diphtheria by its appearance. Schultz held that the cells were monocytes and not lymphocytes and that the blood changes were due to a constitutional lymphatic reaction. Though Schultz's views were widely accepted, lengthy discussions as to the nature of the cells took place (Baar, Hopmann, Preuss).

Criticisms of Schultz's views began to appear in German literature, first on the ground that the cells were lymphocytes, secondly because similar blood changes were reported in cases with much slighter faucial symptoms, and thirdly on the ground that the blood changes were symptoms of a "morbus" and not a constitutional abnormal reaction (Brogsitter, Kwasniewski and Henning, Schmidheiny). In 1927 Schultz with Mirisch agreed haltingly that the cells were lymphocytes, but refused to accept the identity of cases with and without angina in spite of the identity of the hæmatological changes and of the enlargement of the glands and spleen. They upheld the constitutional lymphatic reaction in their type.

The differentiation of monocytic angina from glandular fever and the theory of a constitutional lymphatic reaction thus continued and articles on the same lines followed up to 1929 from Hartwich, Lenhartz, Hrabowski, and Feer, and indeed are still appearing. As Nyfeldt says, "monocytic angina nearly pushed out glandular fever."

The argument that monocytic angina is glandular fever was put forward on the continent by Glanzmann in his monograph on Glandular Fever in 1930, by Nyfeldt in 1932, and by Lehndorff and Schwarz in various articles and in their monograph in 1932. The evidence for the identity of monocytic angina and glandular fever is as follows :—

(1) In epidemics of glandular fever, cases occur with and without angina of all grades, and between the two groups no difference can be found in the blood changes, the glandular swelling, and the enlargement of the spleen.

(2) The cases with membranous angina cannot be distinguished from monocytic angina.

(3) Similar changes in the mononuclear cell are found only in glandular fever and monocytic angina (except possibly in rubella), so far as is at present known.

(4) Monocytic angina differs from other forms of angina in (*a*) the long prodromal period ; (*b*) the long duration of the angina and fever ; (*c*) the general glandular enlargement ; (*d*) the frequency of recrudescences.

It may now be accepted that monocytic angina is a type of glandular fever. It will be described clinically as the *anginose* type.

FEBRILE TYPE: THE ENGLISH EPIDEMIC OF 1930

During the years 1920–24 glandular fever must have been prevalent throughout this country. Epidemics occurred in many schools. Between 1925 and 1928 it was rare.

In 1930 there was an extensive epidemic in England, which differed widely from those previously recognised. It was characterised by especially attacking adults, by the prolonged and often severe pyrexia, by the occurrence of an eruption often *indistinguishable* from typhoid, and by the late onset of the glandular enlargement, often mild in degree, and of the lymphocytosis. At the beginning of May attention was drawn to the epidemic (Tidy); further evidence then quickly appeared from Krestin, Cantor, Evans and Robb, Balme, Loewy, and Hall. Cantor suggested that glandular fever of this type had three stages: (1) stage of onset, with pyrexia and malaise; (2) stage of eruption, from the fourth to the seventh or tenth day; and (3) stage of glandular enlargement, from the tenth day onwards. There is no doubt that this is correct, and expresses briefly the characters of this febrile type of glandular fever.

Parkes Weber and Rolleston especially called attention to the transient positive Wassermann reaction. The presence of an absolute lymphocytosis was noted by all observers. It develops in the third stage with the glandular enlargement.

By the autumn of 1930 the general clinical features of the outbreak were fairly clear. It was extensive over the south of England and extended to the north, but its unusual characters led to frequent errors of diagnosis, especially of influenza, typhoid, and other exanthemata. In October, 1931, a discussion of glandular fever was held at the Royal Society of Medicine, which was practically devoted to this epidemic. Series of cases were reported from Reading by Mills, and from Birmingham by Williams, as well as from London. There is little other literature on this outbreak or this type.

There can be no doubt that this is a type of glandular fever. Its course appears to represent the *full* development of glandular fever with a prodromal period, a stage of eruption, and a stage of glandular enlargement. Other types and varieties arise from certain phases of the full course being exaggerated and others being absent. It was practically confined to adults in 1930, but cases at younger ages are now known. There are only scanty records of previous epidemics of this type. Botschkowsky in 1900 in Russia, and Spencer in 1926 in America, appear to have seen epidemics. A single instance occurs among Longcope's cases published in 1922. Steinfield and Goldberg recorded a case in 1926. It is difficult to find other satisfactory examples.

One may wonder in what guise glandular fever will next make its appearance.

Ætiology

Distribution. — The disease has been recorded throughout Europe except in the extreme south, in North America, China, Australia, and the Falkland Islands. No case is reported from South Africa. With regard to the tropics, the only records are an epidemic in Trinidad described by Cochrane, and two cases in Manila described by Hasselmann. There is no satisfactory case from India.

Age-incidence.—Probably no age is immune to any type. It has been recorded at 4 months by Glanzmann, and at 70 years by Moir, but it is rare over 40 years. The glandular type is commonest between the ages of 6 and 15 years. In adults it tends to be very mild. The febrile type is most common and typical between the ages of 15 and 25 or 30 years. Infectious mononucleosis is a mild "febrile type," and occurs mainly at the same ages. The anginose type is most common between 10 and 25 years; it also occurs in young children, but is rarely of the same severity.

The incubation period appears to lie usually between

papular eruption, or, as some observers prefer, a roseolar eruption. The spots are commonly 2 to 5 mm. in diameter, pink or pinkish-brown in colour, and may disappear on pressure. In number they are generally scanty, about eight to ten spots, but they may be fairly numerous. They are distributed principally on the front of the trunk, but may also be scattered over the back and limbs, and a few spots rarely may appear on the face. They are not irritable. A crop fades in about four days. There is usually only one crop, but further crops may develop or may appear in a relapse. The eruption thus presents a close resemblance to typhoid. Sometimes the spots are more raised and rather larger than typhoid, but in others it is difficult to find any point of differentiation.

An eruption does not always develop. It is difficult to estimate its frequency. It was present in nearly every adult case which I saw in 1930, but if scanty it is easily overlooked.

The constitutional symptoms become more marked during this stage. The temperature rises to 102° to 104° at the onset of the eruption. It is usually sustained during the presence of the rash, then becomes remittent and tends to fall gradually. The pulse-rate may remain at about 100. Sweating is often profuse, and rigors may occur. Epistaxis is not uncommon. Gastro-intestinal symptoms are usually slight or absent, though there may be constipation with some abdominal distension. Vomiting is rare. Occasionally there is complaint of abdominal pain towards the end of the stage. The spleen is not usually palpable. The Wassermann reaction occasionally becomes positive during this period.

The duration of this stage, until the glandular enlargement appears, is commonly 10 to 14 days, but may be three weeks. Towards the end there may be considerable exhaustion. The diagnosis of typhoid fever is frequently made, in spite of the negative agglutination and bacteriological tests.

Stage of glandular enlargement.—The lymphatic glands commonly become palpable about the end of the third week, between the eighteenth and twenty-fifth days. There is considerable variation, and the limits may be stated as the tenth to the thirtieth days. The groups which enlarge are the same as in the glandular type, but they rarely attain to the same size. They may be slightly tender, but are often discovered on routine examination due to the rise of temperature. They may continue to increase in size for several days. The spleen often becomes palpable during this period, but rarely is more than one or two fingers-breadth below the costal margin. Faucial symptoms are uncommon.

The temperature generally rises again with the development of the glands, and may reach 102° or even 104°. It is usually remittent for about two weeks and then becomes intermittent and gradually falls to normal in the course of a further two or more weeks. The constitutional symptoms usually ameliorate during this stage, though there is often considerable exhaustion. The Wassermann reaction is positive in this stage in a considerable proportion of cases, but it becomes negative before the temperature reaches normal.

The duration of this stage may be prolonged. It lasts until the temperature is normal and the main swelling of the glands has subsided. The duration of the temperature is usually about four weeks, but may be many weeks or even months. Convalescence then gradually sets in.

Relapses and recurrences are not uncommon. An eruption may appear for the first time and a short course of rash and glandular enlargement may be passed through. In other cases there are recurrent rises of temperature which may prolong the course over many months. With these rises the glands may or may not enlarge, but in general the longest pyrexias are associated with comparatively slight enlargement of the superficial glands.

Variations in Clinical Types

Infectious mononucleosis.—The type of glandular fever described in America as infectious mononucleosis especially occurs among young adults—e.g., students and nurses. The general course resembles the febrile type of a mild degree.

Infants and young children.—Glandular fever is rarer at such ages than in older children and younger adults, and is not usually severe, although all three types occur. The course is often less typical, and may exhibit features of all types in a short period. Rashes are variable, and the rubelliform type is commoner than the maculo-papular. The rash may occur at any stage, either before, after, or with the glandular enlargement. The blood may exhibit rapid and marked changes, and counts above 40,000 leucocytes are confined to infants and young children.

Visceral forms.—The visceral glands may enlarge in glandular fever. The enlargement of thoracic and abdominal glands has already been referred to.

More obscure are cases with abdominal pain and absolute lymphocytosis, and no palpable glands, peripheral or otherwise. The cases recorded vary widely in their clinical course. Many have been characterised by prolonged pyrexia, severe constitutional symptoms, and enlarged spleen and liver, the duration being up to many months. But milder courses are met with. Appendicitis may be simulated. Finally, there are cases with no more manifestation than a transient lymphocytosis discovered by chance. There is no conclusive evidence for the diagnosis of glandular fever in many of these since there may be other factors at present unknown. Many cases have been published, all of which have recovered (Glanzmann, Mills, Schmidheiny, Tidy, Parkes Weber, Wilson, and Cunningham).

Eruptions

There is no characteristic eruption constant for all types. In the glandular and anginose types eruptions are rare—especially among children between 6 and 15 years of age. Urticaria occasionally develops. Amongst younger children and infants eruptions are more frequent and variable, and may be urticarial, erythematous, or rubelliform.

Character of eruptions.—There are two important types: (1) a macular eruption in the febrile type, and (2) a rubelliform eruption, mainly in young children. In the febrile type, in the English 1930 epidemic, the rash was a prominent feature and present in the majority of cases. It was usually referred to as a maculo-papular or roseolar eruption, and closely resembles enteric. It has been described fully in the section on the febrile type. It is rare in childhood. In the ordinary course it fades before the glands become palpable; this is almost invariably so in adults. The rubelliform eruption occurs mainly among young children. It may appear at the onset, before or with the glandular enlargement, or later in the attack. Glanzmann is convinced that in many cases it is indistinguishable from rubella, and also that the occipital glands are frequently enlarged. As in rubella, the eruption may be confluent in parts and discrete in others. Other authorities describe it as scarlatiniform.

Eruptions may develop which have been variously abdominal masses which have subsequently disappeared, but I doubt if they are common.

Spleen and liver.—The spleen is frequently palpable. It is difficult to say how often; in half the cases at least. The enlargement is rarely more than one or two fingers-breadth below the costal margin and it is not tender. Its presence and its size bear no relation to the severity of the attack. There is no rule as to when it appears in the course of the glandular type, but it is usually later than the glands. It may persist for long periods, even months or years after the attack has passed. The liver may also enlarge, as Pfeiffer noted, but this is rarely a marked feature and is not often tender.

Course.—The definite mass of glands rarely remains more than two or three days and then subsides rapidly. The temperature falls with the glands and the fall may be so rapid as to suggest a crisis. The general symptoms subside at the same time. This is often the termination of the acute attack and convalescence sets in. The glands, however, though much smaller, are often palpable for a considerable period, and have been known to persist for more than a year. Suppuration of the glands and septic complications are no part of the ordinary course of glandular fever and are extremely rare.

Recrudescences are very common. If the main mass has been confined to one side, the other side may subsequently enlarge. This may be while the initial mass is still present or after it has diminished. The pyrexia and symptoms return, and the course is similar to the original attack.

Recurrences may take place after considerable periods of freedom and are not uncommon after several weeks. There may be several recurrences over a period of three or four months, the severity gradually decreasing. In rare cases they have extended over several years.

Convalescence.—Immediate convalescence is rapid, except in cases with recurrence. There is, however, a definite tendency for a long period of slight but appreciable debility to follow an attack. Some degree of anæmia may develop. This may last for 6 to 12 months, but leaves no permanent results or ill-effects.

Prognosis.—The final prognosis is uniformly good in the absence of rare complications, and there are no permanent ill-effects.

ANGINOSE TYPE

(Monocytic Angina)

The type which will be described here principally refers to cases in which a membrane is present on or near the tonsils clinically indistinguishable in its appearance from diphtheria. Diphtheria bacilli are absent. Various cocci are present, and Plaut-Vincent organisms are often found. This type is rarer than the glandular form, and it is not infectious at this stage. It is commonest between 10 and 25 years of age, and under 10 years it is rarely severe. It must be noted that lesser grades of faucial change may be associated with a similar course.

There is a prodromal period of considerable length, from one to three weeks, during which there is increasing malaise and pyrexia, without any definite physical signs. Complaints of the throat begin to be made, at first slightly and then more seriously. On examination the membrane may already be formed. The temperature often reaches 104°. More rarely the angina may develop in the course of a glandular type, but it does not occur as an initial symptom. The tonsils, if seen before the development of the membrane, are red and swollen. The membrane when formed has the colour and distribution of that of diphtheria, is indistinguishable from it, and it may be unilateral or bilateral. The uvula is frequently œdematous and the membrane may extend over it. The breath may be odourless or with varying degrees of fœtor.

Peritonsillar œdema is common, but a tonsillar abscess is rare. Even when this occurs, suppuration of the lymphatic glands seldom follows, though many of the recorded cases of suppuration in glandular fever have been in this type.

Membrane never forms in the nose and never in the larynx. There may be severe discomfort from œdema of the tissues, but laryngeal obstruction is unknown.

The cervical lymphatic glands are always enlarged by the time the membrane is present, but they do not form such large masses as in the glandular type. Œdema of the neck and considerable tenderness is common at the height of the faucial changes and palpation of the cervical glands may be difficult. Some axillary glands are palpable in most cases. The spleen may be palpable, but perhaps less often than in the glandular type.

There is considerable discomfort and mental anxiety when the faucial changes are at a maximum, especially with œdema of the neck, but the constitutional disturbances are not in proportion to these features or to the temperature, and the patient usually looks fairly well. The heart does not suffer, either temporarily or subsequently. Eruptions are practically unknown.

General course.—The membrane may persist for many days, unlike that of diphtheria. As it separates the fever tends to fall, the fauces become more comfortable, and convalescence is often rapid. In some cases, however, pyrexia, about 100°, may persist for several weeks. This is sometimes due to recurrences which are not infrequent, but rarely attain the severity of the original attack. The special complications which occur in diphtheria are unknown. Diphtheritic antiserum has no effect. A few fatalities have resulted from broncho-pneumonia and general sepsis, but apart from these, recovery has been complete and there are no permanent ill-effects.

FEBRILE TYPE

There is a fairly characteristic course for this type in adults, although many variations occur. In children the course and sequence of the manifestations are less constant and rarely so severe. Three stages may be recognised:—

Stage of invasion.—The onset is usually sudden with headache, malaise, and a temperature of 102° to 103°. There may be one or two rigors. Less often the onset is insidious and vague. Sore-throat is rarely complained of in adults, though the fauces may be reddened. Headache is frontal and often occipital and may be so severe as to suggest meningitis. The face is flushed and the skin moist. Photophobia and conjunctivitis are common. There is no enlargement of glands or spleen at this stage. Gastro-intestinal symptoms are absent. There is no regular course for the temperature. The pulse is not specially rapid and when the temperature is high the rate may be disproportionately slow.

The stage lasts until the appearance of the eruption, and thus has a duration commonly of three to seven days, but it may be as long as ten days.

Stage of eruption.—The rash appears usually between the fourth and seventh days, most commonly on the fourth or fifth. It may be delayed as long as the tenth day. The most common type consists of macules or papules, and may be described as a maculothe demonstration of the existence of this antigen and of its immunological significance.

Four strains, representing the two extreme types described in the previous paper (Felix and Pitt[2]), were selected for the preparation of vaccines and were used for the immunisation of mice, since Grinnell[3] and Perry, Findlay, and Bensted[4] had shown that the mouse is a very suitable experimental animal for virulence and protection tests with *B. typhosus*. The vaccines were saline suspensions of 24 hour agar cultures, standardised by opacity and killed by heating for 1½ hours at 58° C. Mice weighing between 26 and 28 g. were inoculated subcutaneously at three days' interval, the first dose containing 200 × 10⁶, the second 400 × 10⁶ organisms. Twenty-four days later the test dose was inoculated, intraperitoneally, consisting of 2 M.L.D. (= 200 × 10⁶ organisms) of our most virulent inagglutinable strain Ty 2. The technical details observed in this and the subsequent infection experiments have been described in the previous paper.[2]

It is seen (Table I.) that the two vaccines prepared from inagglutinable and highly virulent strains conferred a very high degree of protection, whereas those made from the two agglutinable strains of low virulence were devoid of protective action. The clear-cut result of this experiment permitted one interpretation only—i.e., that the factor responsible for inagglutinability and virulence is an antigen and that the corresponding antibody is a powerful protecting agent. Attempts were therefore made to demonstrate this antibody by in-vitro tests.

TABLE I.—*Active Immunisation*

Vaccines used for the immunisation of mice.		Number of mice tested by intraperitoneal inoculation of strain Ty 2 (200 ×10⁶ organisms).	
Strain.	Type.	Tested.	Survived.
Ty 2	Inagglutinable smooth. Virulence high.	20	18
Gigliotti.		19	17
Ty 8	Agglutinable smooth. Virulence low.	22	1
Rawlings.		20	1
Controls with normal mice—			
Full test-dose (200 ×10⁶ organisms)		20	0
Half test-dose (100 ×10⁶ organisms)		16	0

Demonstration of the Virulence Antigen (Vi)

Previous experiments with inagglutinable and agglutinable smooth strains had failed to reveal any antigenic difference between the two types. Suspensions of the inagglutinable or resistant strains, when used in the living state in agglutination and absorption tests, were unable to react with the O antibody. However, when killed by heat or by treatment with various chemicals these suspensions were agglutinated by O immune serum to titre limit and quantitative absorption tests with standardised suspensions showed that sensitive and non-sensitive strains did not differ in their content of the smooth O antigen. Furthermore, in rabbit immune sera prepared by inoculation of inagglutinable strains, killed by heating at 60° C., no residual agglutinin for the homologous strain was demonstrable when the O agglutinin had been removed by absorption with an agglutinable strain. These results seemed to justify the statement made in the previous paper[2] that the two types of strain did not differ in their antigenic composition.

Although the protection experiment recorded in Table I. clearly indicated the presence in the inagglutinable strains of a separate antigen which withstood heating to 58° C., it was thought possible that this treatment might impair its agglutinogenic value and thus preclude the demonstration of the corresponding antibody by agglutination methods. Rabbits were therefore immunised with suspensions of living organisms of the two types of *B. typhosus* and control rabbits were inoculated with suspensions heated at various temperatures. The strain "Mrs. S." which had been used in earlier experiments by Ledingham[5] and Arkwright[6] was also included in the series; this strain is of the type of intermediate agglutinability and virulence and represents the most common type of *B. typhosus*.

Four intravenous inoculations were given at intervals of two days. The suspensions of living organisms and those killed by heating at 58° C. were each time freshly prepared from 24 hour agar cultures, while those heated at 70° C. and 100° C. were prepared in bulk and stored in the cold. The total number of organisms inoculated is stated in the Table. One week after the last inoculation blood was drawn from the jugular and tested against fresh saline suspensions of living organisms of the inagglutinable and agglutinable types. The technique of the agglutination tests was the same as described in the previous paper.[2]

It is seen from Table II. that the immunisation with living organisms of the three inagglutinable strains and of the intermediate strain "Mrs. S." led to the production of an antibody which was absent from the sera of the rabbits inoculated with living agglutinable organisms and also from those immunised with heated suspensions of the two most virulent and inagglutinable strains Ty 2 and Gigliotti. The symbol "Vi" is used for this antibody, since it is proposed to designate the new antigen as the "Virulence antigen" and to refer to it as the "Vi" antigen.

TABLE II.—*Agglutination Test*

Rabbits immunised with strains of *B. typhosus*.				Titres of the antibodies present in the sera.		
Rabbit.	Type of strain.	Strain.	Dose in million of organisms.	H	O	Vi
	Inaggl. Virulence high.	Ty 2—				
62		Live	800	10,000	5,000	400
63		Heated 1½ hrs. at 58°	800	20,000	20,000	0
64		„ 1 hr. „ 70°	800	1,000	5,000	0
65		„ 1 „ „ 100°	800	200	20,000	0
		Gigliotti—				
67		Live	800	5,000	5,000	100
68		Heated 1½ hrs. at 58°	800	10,000	20,000	0
69		„ 1 hr. „ 70°	800	2,000	20,000	0
70		„ 1 „ „ 100°	800	0	20,000	0
74		Watson. Live ..	800	5,000	2,000	200
75	Intermediate.	"Mrs. S." Live ..	800	20,000	10,000	50
71	Aggl. Virulence low.	Ty 8. Live	1600	20,000	5,000	0
72		Ty 901. Live	1600	20,000	10,000	0
73		Rawlings. Live ..	1600	5,000	20,000	0

Titre 0 = a negative result in a dilution of 1 in 20.
Aggl. = agglutinable.

The Vi antibody is capable of clumping the inagglutinable strains, whereas the O antibody is unable to produce this effect. The macroscopic appearance of the Vi agglutination is very similar to that of O agglutination: small granules of uniform size are formed, which settle slowly and leave the supernatant fluid perfectly clear. The titre of this described as urticaria, erythema nodosum, or morbilliform. These are usually transient. Rolleston saw a case diagnosed as typhus. Goldman observed absolute lymphocytosis in a case diagnosed as chicken-pox. Herpes labialis has been recorded many times. I have never seen it in the ordinary glandular type.

Complications

Sepsis.—Suppuration of the glands is no part of glandular fever. Secondary infections must naturally sometimes occur, but are very rare. In infants retropharyngeal abscess may develop ending in suppuration of the glands. Glanzmann had only one case of suppuration amongst many hundreds of cases in infants and children. Personally I have never seen the glands suppurate.

The rarity of suppuration is especially striking in the anginose type; although suppuration often appears imminent, it rarely develops. Nevertheless many of the recorded cases have been in this type. In the febrile type there is no record of the occurrence of suppuration. The rarity of sepsis applies also to such complications as otitis media, mastoiditis, and antritis. When they occur the course is usually benign.

Epistaxis is not uncommon. It may occur at any time in the course. It may be so severe as to cause anæmia. In the febrile form it may be severe before the glands enlarge.

Hæmaturia was mentioned by Heubner in speaking on Pfeiffer's original communication. In 1921 Morley and I collected the statistics of 270 cases of glandular fever, which gave an incidence of 6 per cent. for hæmaturia. It may be the first symptom for which a doctor is consulted. It is uncertain whether it should be regarded as "acute hæmorrhagic nephritis," or as a simple bleeding. In any case it appears to be a harmless manifestation. I have watched several cases over a course of years and I have never known nephritis to develop. Hæmaturia may occur in any type, and is not commoner in the anginose type or with severe sore-throats. Large epidemics have been recorded without any example.

Purpura and skin hæmorrhages are extremely rare. Altogether I can only find five recorded cases (Downey and McKinlay, Königsberger, Lewin, Minot, and Williams). These were severe but complete recovery occurred in all. In Minot's case the thrombocytes were reduced, but there is no record in the others. Other hæmorrhages are very rare, but I have once seen rectal hæmorrhage with bright blood in a child.

Conjunctivitis is by no means uncommon. I have seen it several times in the glandular type. In the febrile type it is more common. It appears as a dry catarrhal conjunctivitis.

Jaundice is rare, and all recorded cases have been in adults, except one child aged ten years (Glanzmann). It commonly develops after the glandular enlargement, but may precede it in the febrile type. *These cases may be otherwise normal.* The jaundice may be due to pressure of glands in the hilum or to hepatitis. Chevallier and Schmidheiny, during epidemics, saw cases with jaundice and lymphocytosis, but without any swelling of peripheral glands.

Meningeal symptoms.—Pain and spasm of the neck muscles and headache may be sufficiently severe to suggest meningitis. A case of Epstein and Dameshek's is evidence that the meninges may be involved. The cerebral symptoms were marked, and there was a typical lymphocytosis. On lumbar puncture the fluid was under high pressure, and contained numerous lymphocytes. A similar case has been published by Johansen. Both cases recovered.

Wassermann reaction.—In the 1930 epidemic the reaction was found to be positive in about half the cases tested. It usually became positive in the second week and persisted for some weeks, and then became negative. It was rarely very strongly positive. Sprunt suggests that this transient reaction is connected with the presence of heterophile antibodies.

Respiratory organs.—A slight cough is not uncommon, and may be attributed to the condition of the fauces. Bronchitis and broncho-pneumonia or pneumonia have been recorded many times. Recovery is usual but fatal terminations have occurred, and this must be regarded as a serious complication.

(To be concluded)

A NEW ANTIGEN OF B. TYPHOSUS

ITS RELATION TO VIRULENCE AND TO ACTIVE AND PASSIVE IMMUNISATION

By A. Felix, D.Sc. Vienna

MEMBER OF SCIENTIFIC STAFF, LISTER INSTITUTE; AND

R. Margaret Pitt, B.A. Camb.

(From the Bacteriological Department, Lister Institute, London)

The newer knowledge of antigenic structure and antigenic variation of bacteria, accumulated during the last fifteen years, has altered very considerably the older conception of the mechanisms concerned in specific antibacterial immunity. It is now generally recognised that separate and distinct antigenic components of the bacterial cell play quite different rôles in immunity and immunity reactions.

In the case of the flagellated bacilli the important factors are the O antigens and the corresponding antibodies, while the flagellar H antigens and the antibodies that react with them are of no protective value in active and passive immunisation. Smooth-rough variation, which does not affect the flagella but is associated with partial or complete deterioration of the specific smooth O antigen, concurrently reduces and eventually annuls the immunogenic value of bacteria undergoing this type of variation. The smooth O antigen, or more particularly the so-called type-specific polysaccharide, which is its most important constituent, is also held responsible for the high virulence of smooth bacteria as contrasted with the low virulence of rough variants (for references see Topley[1]).

In a recent paper (Felix and Pitt[2]) we have shown that in the special case of *B. typhosus* virulence is intimately associated with resistance to the action of the O antibody. Inagglutinable strains are highly virulent, whereas agglutinable strains are of low virulence. Both types of strain showed the general characters of smoothness and did not differ in their content of smooth O antigen. The conclusion therefore appeared inevitable that in the case of *B. typhosus* the mere presence of smooth O antigen does not of itself determine high virulence, and that some unknown factor is required to render this antigen resistant to the action of the O antibody.

The nature of this factor at first appeared entirely obscure. Further experiments, however, revealed the surprising fact that it is itself an antigen, separate and distinct from the long-established O and H antigens of *B. typhosus*. The subject of the present paper is the demonstration of the existence of this antigen and of its immunological significance.

Four strains, representing the two extreme types described in the previous paper (Felix and Pitt[2]), were selected for the preparation of vaccines and were used for the immunisation of mice, since Grinnell[3] and Perry, Findlay, and Bensted[4] had shown that the mouse is a very suitable experimental animal for virulence and protection tests with *B. typhosus.* The vaccines were saline suspensions of 24 hour agar cultures, standardised by opacity and killed by heating for 1½ hours at 58° C. Mice weighing between 26 and 28 g. were inoculated subcutaneously at three days' interval, the first dose containing 200 × 10^6, the second 400 × 10^6 organisms. Twenty-four days later the test dose was inoculated, intraperitoneally, consisting of 2 M.L.D. (= 200 × 10^6 organisms) of our most virulent inagglutinable strain Ty 2. The technical details observed in this and the subsequent infection experiments have been described in the previous paper.[2]

It is seen (Table I.) that the two vaccines prepared from inagglutinable and highly virulent strains conferred a very high degree of protection, whereas those made from the two agglutinable strains of low virulence were devoid of protective action. The clear-cut result of this experiment permitted one interpretation only—i.e., that the factor responsible for inagglutinability and virulence is an antigen and that the corresponding antibody is a powerful protecting agent. Attempts were therefore made to demonstrate this antibody by in-vitro tests.

TABLE I.—*Active Immunisation*

Vaccines used for the immunisation of mice.		Number of mice tested by intra-peritoneal inoculation of strain Ty 2 (200 ×10^6 organisms).	
Strain.	Type.	Tested.	Survived.
Ty 2 Giglioli.	Inagglutinable smooth. Virulence high.	20 19	15 17
Ty 8 Rawlings.	Agglutinable smooth. Virulence low.	22 20	1 1
Controls with normal mice—			
Full test-dose (200 ×10^6 organisms)		20	0
Half test-dose (100 ×10^6 organisms)		16	0

Demonstration of the Virulence Antigen (Vi)

Previous experiments with inagglutinable and agglutinable smooth strains had failed to reveal any antigenic difference between the two types. Suspensions of the inagglutinable or resistant strains, when used in the living state in agglutination and absorption tests, were unable to react with the O antibody. However, when killed by heat or by treatment with various chemicals these suspensions were agglutinated by O immune serum to titre limit and quantitative absorption tests with standardised suspensions showed that sensitive and non-sensitive strains did not differ in their content of the smooth O antigen. Furthermore, in rabbit immune sera prepared by inoculation of inagglutinable strains, killed by heating at 60° C., no residual agglutinin for the homologous strain was demonstrable when the O agglutinin had been removed by absorption with an agglutinable strain. These results seemed to justify the statement made in the previous paper[2] that the two types of strain did not differ in their antigenic composition.

Although the protection experiment recorded in Table I. clearly indicated the presence in the inagglutinable strains of a separate antigen which withstood heating to 58° C., it was thought possible that this treatment might impair its agglutinogenic value and thus preclude the demonstration of the corresponding antibody by agglutination methods. Rabbits were therefore immunised with suspensions of living organisms of the two types of *B. typhosus* and control rabbits were inoculated with suspensions heated at various temperatures. The strain "Mrs. S." which had been used in earlier experiments by Ledingham[5] and Arkwright[6] was also included in the series; this strain is of the type of intermediate agglutinability and virulence and represents the most common type of *B. typhosus.*

Four intravenous inoculations were given at intervals of two days. The suspensions of living organisms and those killed by heating at 58° C. were each time freshly prepared from 24 hour agar cultures, while those heated at 70° C. and 100° C. were prepared in bulk and stored in the cold. The total number of organisms inoculated is stated in the Table. One week after the last inoculation blood was drawn from the jugular and tested against fresh saline suspensions of living organisms of the inagglutinable and agglutinable types. The technique of the agglutination tests was the same as described in the previous paper.[2]

It is seen from Table II. that the immunisation with living organisms of the three inagglutinable strains and of the intermediate strain "Mrs. S." led to the production of an antibody which was absent from the sera of the rabbits inoculated with living agglutinable organisms and also from those immunised with heated suspensions of the two most virulent and inagglutinable strains Ty 2 and Giglioli. The symbol "Vi" is used for this antibody, since it is proposed to designate the new antigen as the "Virulence antigen" and to refer to it as the "Vi" antigen.

TABLE II.—*Agglutination Test*

Rabbits immunised with strains of *B. typhosus.*				Titres of the antibodies present in the sera.		
Rabbit.	Type of strain.	Strain.	Dose in million of organisms.	H	O	Vi
	Inaggl. Virulence high.	Ty 2—				
62		Live	800	10,000	5,000	400
63		Heated 1½ hrs. at 58°	8000	20,000	20,000	0
64		„ 1 hr. „ 70°	8000	1,000	50,000	0
65		„ 1 „ „ 100°	8000	200	20,000	0
		Giglioli—				
67		Live	800	5,000	5,000	100
68		Heated 1½ hrs. at 58°	8000	10,000	20,000	0
69		„ 1 hr. „ 70°	8000	2,000	20,000	0
70		„ 1 „ „ 100°	8000	0	20,000	0
74		Watson. Live ..	800	5,000	2,000	200
75	Inter-mediate.	"Mrs. S." Live ..	800	20,000	10,000	50
71	Aggl. Virulence low.	Ty 8. Live	1600	20,000	5,000	0
72		Ty 901. Live	1600	20,000	10,000	0
73		Rawlings. Live ..	1600	5,000	20,000	0

Titre 0 = a negative result in a dilution of 1 in 20.
Aggl. = agglutinable.

The Vi antibody is capable of clumping the inagglutinable strains, whereas the O antibody is unable to produce this effect. The macroscopic appearance of the Vi agglutination is very similar to that of O agglutination; small granules of uniform size are formed, which settle slowly and leave the supernatant fluid perfectly clear. The titre of this antibody is very much lower than those of O and H antibodies, the highest Vi titre observed in the present series not exceeding a dilution 1 in 400.

All the virulent strains reacted with all the sera containing the Vi antibody, thus indicating uniformity of the antigen concerned. The intensity of the reaction showed a definite relationship to the degree of virulence. The Watson strain was most readily clumped by the Vi antibody, next followed the strain Giglioli, and then Ty 2. This is the inverse order of their relative virulence.[2] The Vi titres recorded in Table II. represent those observed with the strain Watson as test strain.

The independence of the Vi antibody of the accompanying O and H agglutinins was readily demonstrated by absorption tests. Table III. illustrates in much abridged form the results obtained in numerous experiments.

TABLE III.—*Agglutinin Absorption Test*

Type of antibody.	Titre of agglutination.						
	Rabbit serum 62 II. (versus strain Ty 2, live). 1·5 c.cm. of dilution 1 in 20 absorbed with suspensions of living organisms of strains.						Control serum unabsorbed.
	Giglioli. 40,000 mill.	Watson 40,000 mill.	Mrs. S. 80,000 mill.	Ty 1. 160,000 mill.	Ty 901. 240,000 mill.	Rawlings. 240,000 mill.	
H	1000	500	1000	0	0	0	10,000
O	2000	2000	1000	500	0	0	5,000
Vi	0	0	0	0	400	400	400
Type of strain	Inagglutinable.		Intermediate.		Agglutinable.		

Titre 0 = a negative result in a dilution of 1 in 100.

It will be observed that the titre of the Vi antibody remained entirely unaltered after the O and H agglutinins had been removed from the serum by absorption with living organisms of the highly agglutinable type of *B. typhosus*. These strains were unable to reduce the Vi titre although the serum was treated with enormous numbers of organisms. On the other hand all the inagglutinable and intermediate strains tested removed the Vi antibody readily, irrespective of whether the O and H agglutinins were simultaneously removed or reduced.

In certain experiments especially designed to decide whether there was any summation effect in the agglutinating action of the Vi and O antibodies it was found definitely that neither of them was capable of enhancing the action of the other.

It is at present a matter for speculation what exactly the mechanism is by means of which the Vi antigen renders the smooth O antigen in the living organisms resistant to the action of the O antibody. The supporters of the surface theory of antigen-antibody action undoubtedly will welcome the phenomenon as additional evidence of the correctness and general validity of the theory.

For the purposes of the present investigation the main results of the in-vitro tests are: (1) the demonstration of the existence of the Vi antigen and (2) the evidence of its presence in strains of intermediate agglutinability and virulence, which represent the most common type of *B. typhosus*.

ITS PROTECTIVE ACTION IN PASSIVE IMMUNISATION

The rabbit sera described in the previous section and other sera obtained from subsequent bleedings of the immunised rabbits were next tested for protective action against infection with the most virulent strain Ty 2. The sera were kept without the addition of any disinfectant and the sterility of each sample was ascertained prior to its being used for intramuscular inoculation into mice. One to two days after the serum injections the test dose was inoculated intraperitoneally. Table IV. gives a sample experiment.

TABLE IV.—*Passive Immunisation*

Rabbit sera injected into mice intramuscularly two days prior to test dose.					Number of mice tested by intraperitoneal inoculation of strain Ty 2 (150×10^6 organisms).	
Serum No.	Titre of antibodies present in the serum.			Dose of serum in c.cm.		
	H	O	Vi		Tested.	Survived.
62 II.	10,000	5,000	400	0·5	4	4
				0·25	4	4
				0·1	4	3
74 II.	5,000	2,000	200	1·0	4	4
				0·5	4	0
64 II.	1,000	50,000	0	1·0	4	0
72 II.	20,000	10,000	0	1·0	4	0
73 II.	5,000	20,000	0	1·0	4	0
Controls with normal mice—						
Full test dose (150×10^6 organisms)					4	0
Half the test dose (75×10^6 organisms)					4	0

The results reproduced in this Table do not call for much comment. The two sera containing Vi antibody exert a powerful protective action, whereas the three sera devoid of Vi antibody are of no protective value whatsoever. The serum No. 62 II. with the higher content of Vi antibody (titre 1 in 400) has a much higher protective power than the serum No. 74 II. with the lower content of this antibody (titre 1 in 200).

The potency of the Vi antibody in protective action appears particularly striking in view of the comparatively low titres of its in-vitro action, which are in contrast to the high titres of the O antibody. The H titres, although for the sake of completeness recorded in Table IV., need not be considered in this connexion, since it is well known that H antibodies are negligible as protective agents. The O antibody, however, whose important rôle in antibacterial immunity is firmly established, makes a curiously poor performance in this experiment, when an in-vitro titre of 1 in 50,000 finds no expression in the in-vivo action.

The Vi antibody was also tested for protective action in the absence of the O and of both the O and H antibodies. The serum No. 62 II. was by repeated and massive absorption freed from these latter antibodies, until none were demonstrable in a dilution of 1 in 20. The Vi titre remained unaltered and the absorbed sera were found as potent in protective action as was the unabsorbed serum.

Differing Rôles of the Vi and O Antibodies

The protection experiments described in previous sections were all planned with a view to testing the efficacy of active or passive immunisation by subsequent infection with a strain of extreme inagglutinability and highest virulence. To obtain a more complete picture an experiment was conducted in a different way.

Two batches of mice, each numbering fifty, were immunised by subcutaneous inoculation of vaccines prepared from strains of the two extreme types. The vaccine from the virulent strain Ty 2 was given in the same dose as in the experiment described in Table I.—i.e., 200 and 400 million organisms at two days interval; the vaccine from the avirulent strain Ty 901 was used in twice that amount, since previous experience with vaccines from this type of strain (Table I.) had shown that the smaller doses had no protective effect. Each batch of the immunised mice was then divided into four groups and these were tested, along with groups of control animals, by intraperitoneal inoculation of 2 M.L.D. of the two strains which had been used for the protective inoculations and also of two strains of intermediate agglutinability and virulence.

The result of this experiment (Table V.) appeared difficult to interpret. If the figures for the two intermediate strains are first disregarded and only those for the two extreme types Ty 2 and Ty 901 are considered, it will be seen that each vaccine protected only against infection with the homologous strain, and that in the case of the strain Ty 901 the degree of protection was not very high. The inefficiency of the vaccine from Ty 901 in protection against Ty 2 is in accord with the results shown in Table I. and is readily explained by the absence from this vaccine of Vi antigen. The failure of the vaccine from Ty 2 to protect against the strain Ty 901 is obviously due to the insufficient quantity of O antigen administered by the protective inoculations, since this vaccine has been used in half the dose of that of strain Ty 901.

TABLE V.—*Active Immunisation. Protection against Infection with different types of* B. typhosus

Test dose inoculated intraperitoneally.				Mice immunised with vaccines from strain.				Controls. Normal mice tested with			
Days after second dose of vaccine.	Strain.	Type.	Dose in million of organisms.	Ty 2. (Dose 600×10^6.)		Ty 901. (Dose 1200×10^6.)		Full test dose.		Half test dose.	
				T.	S.	T.	S.	T.	S.	T.	S.
17	Ty 2	Inagg. Virulence high.	200	12	12	12	0	12	0	10	0
20	"Mrs. S."	Intermediate	600	11	6	11	0	12	0	10	1
19	Ty 1		800	12	5	12	1	12	0	10	0
18	Ty 901	Agg. Virulence low.	1600	13	1	14	7	14	0	10	2

T. = tested ; S. = survived.

The results obtained with the animals immunised with the vaccine from Ty 901 and infected with the two intermediate strains "Mrs. S." and Ty 1 are also readily interpreted. It has been shown in Tables II. and III. that both these strains possess Vi antigen, which renders them resistant to the action of O antibodies. But the low degree of protection against the two intermediate strains displayed by the mice which had been immunised with the vaccine from strain Ty 2 was rather puzzling. It seemed paradoxical that mice from the same batch of immunised animals should be better protected against the most virulent strain Ty 2 than against the less virulent strains "Mrs. S." and Ty 1. Heterogeneity of the Vi antigen could not be suspected, since the in-vitro tests described in a previous section clearly indicated that this antigen was uniform in all the strains tested.

It will be observed that the number of organisms inoculated as the test dose varied very considerably with the four strains recorded in Table V. To keep the test dose of each strain at the constant level of 2 M.L.D. this procedure was unavoidable. However in the case of Ty 901, the strain of the lowest virulence, the test dose of 1600 million organisms very closely approached that number of bacilli which in previous experiments [2] had been found to produce lethal effects when administered as dead vaccine to mice. It seemed therefore most likely that the unsatisfactory protection against strains of lower virulence was due to the toxic effect of the large inoculum used. This hypothesis was tested in the following experiment (Table VI.).

TABLE VI.—*Neutralisation of Endotoxin*

Rabbit sera: 1 c.cm. of each serum injected into mice intramuscularly two days prior to test dose.				Mice tested by intraperitoneal inoculation of dead vaccine from strain Giglioli. ($10,000 \times 10^6$ organisms.)	
Serum No.	Titre of antibodies present in the serum.				
	H	O	Vi	Tested.	Survived.
62 III.	10,000	2,000	400	4	0
74 III.	2,000	2,000	200	4	1
67 II.	5,000	5,000	100	4	3
67 III.	5,000	2,000	100	4	1
64 II.	1,000	50,000	0	4	4
69 II.	2,000	20,000	0	4	4
72 II.	20,000	10,000	0	4	3
73 III.	5,000	10,000	0	4	2
Controls with normal mice— Full test dose ($10,000 \times 10^6$ organisms)				10	1

The rabbit sera previously used in passive protection experiments were tested for their capacity of neutralising the toxic effect of killed vaccines. The mice received 1 c.cm. of the immune sera intramuscularly and two days later the test dose of killed bacilli was inoculated intraperitoneally. Although it had been shown in the previous paper [2] that the most virulent strains are not more toxic than those of lowest virulence, it was, nevertheless, thought advisable to prepare the test vaccine from a virulent strain in order to obtain a suspension containing both the O and Vi antigens. After preliminary tests for toxicity the dose of 10,000 million organisms of the strain Giglioli, killed by heating for 2 hours at 58° C., was selected as test dose.

It is seen from Table VI. that the four immune sera which contained no demonstrable Vi antibody but had a high content of O antibody possessed a high neutralising power against the toxic effect of the vaccine. Of 16 mice given this type of serum 13 survived. In the corresponding group of 16 mice which had received immune sera rich in Vi antibody but comparatively poor in O antibody only 5 survived. The neutralising effect of the high-titre O sera was also strikingly demonstrated by the different clinical picture observed in the survivors in the two groups. The 5 survivors in the latter group all showed definite symptoms of illness during the first day following the inoculation of the test dose. On the other hand, in the group of mice protected with the high-titre O sera the great majority of the animals which survived showed no symptoms of illness whatsoever.

The result of this experiment clearly indicates that the O antibody has a definite neutralising effect on the so-called endotoxin of *B. typhosus*, whereas the Vi antibody is incapable of this action. This is in accord with the fact that virulence and toxigenicity of *B. typhosus* are independent of each other.[2] Just as the Vi antigen present in virulent strains does not cause any increase in toxicity, so the Vi antibody does not contribute towards the endotoxin-neutralising power of the serum. It is not claimed that the O antigen is the sole factor associated with the toxic action of killed bacilli; other constituents of the bacterial cell may also play a part. But it is the O antibody alone amongst the three different antibodies demonstrable in antityphoid sera that shows a definite relationship to the content of endotoxin-neutralising bodies in the serum.

The O antibody, which is known to exert bactericidal (Felix and Olitzki [15]) and opsonising effects (Braun and Nodake [16]), quite apart from the neutralising action now described, appears to be the sole antibody required in protection against the type of strain of low virulence exemplified in Table V. by the strain Ty 901. The Vi antibody per se is entirely without effect on organisms of this type, since they are devoid of Vi antigen.

Clinical Bearing

The results of the experiments presented in this paper obviously have a direct bearing on the theory and practice of antityphoid inoculation and of serum therapy of typhoid fever. Doubts will possibly be voiced as to whether the facts established in experiments with mice are also valid with regard to the disease in man. Such a view, however, does not seem to carry weight. The basic element in the pathogenesis of typhoid fever is the bacteriæmia. And there is no reason for the belief that the antibacterial defence mechanisms evolved in one animal species are not at work when another species is invaded. In this connexion the fact may well be recalled that in the case of the O and H antibodies it was clinical observation and the analysis of the serum reactions of typhoid patients that first led to the recognition of the different immunological significance of the two types of antibody (Felix [7]). This conclusion was subsequently corroborated by experiments with guinea-pigs (Arkwright [6]) and mice (Topley,[8] Schütze [9]). The Vi antigen and antibody are approached by the opposite route and the relative importance of their effect on the course of the disease in man will be assessed by the clinical pathologist. Two procedures suggest themselves: (1) investigation into the correlation between the severity of the disease and the inagglutinability (i.e., virulence) of the culture of *B. typhosus* isolated from the patient's blood; (2) investigation into the relationship between the clinical course and the appearance of Vi antibodies in the patients' blood-serum.

ANTITYPHOID INOCULATION

With regard to prophylactic inoculation the relevant result is that the Vi antigen must be taken into consideration. The importance of perfect smoothness of the cultures used for making typhoid vaccines, first established by Arkwright [6] and more recently emphasised by Grinnell [3] and Perry, Findlay, and Bensted,[4] will not be diminished as a result of the present investigation. The smooth O antigen remains an essential element in virulence and in immunogenic value. This has been clearly indicated in both the preceding [2] and the present paper. It is evident, however, that in virulence as well as in protective action the smooth O antigen of *B. typhosus* is not the sole factor concerned. It shares its place with the Vi antigen.

It cannot yet be stated exactly in what way this newer knowledge will affect the accepted methods for making typhoid vaccine. The essential properties of the Vi antigen—i.e., resistance to heat, to various chemicals, and to storage—must first be studied adequately. It is obvious, however, that to ensure maximum efficacy of the vaccine the strain or strains selected must have the highest possible content of Vi antigen, in addition to the normal quota of O antigen. In this connexion it is necessary again to emphasise the two facts—namely, that the degree of agglutinability, which reflects the absence or presence of Vi antigen, is a remarkably constant property of different strains of *B. typhosus*; and that the Rawlings strain, which is so widely being used for the preparation of typhoid vaccine, belongs to the sensitive type which is devoid of Vi antigen (Felix [10]). By some curious coincidence it happened that two of the three strains used by Arkwright [6] in his protection experiments, the strains Ty 901 and Rawlings, were of the latter type, while no strain of the inagglutinable and highly virulent type was included in his series.

The possession or lack of Vi antigen, though remarkably constant in strains of *B. typhosus* when maintained under standard conditions, are by no means properties incapable of variation. Perry, Findlay, and Bensted [11] recently accomplished the transformation of the avirulent Rawlings strain into one of high virulence by passage through the mouse, and the present writers observed variations in agglutinability and virulence under varying conditions of growth. The consistent search by Perry, Findlay, and Bensted [12] for a method of increasing the protective value of typhoid vaccine by increasing the virulence of the strain used is undoubtedly an attempt in the right direction. The theoretical basis of this procedure is the high protective value of Vi antigen, demonstrated in the present communication.

It has not yet been investigated whether the facts established in experiments with *B. typhosus* are applicable also to *B. paratyphosus* A and B and more generally to other bacteria which also do not produce the typical exotoxin. Reference should, however, be made to a paper recently published by Day [13] who described "species immunity to virulent streptococci," due to a special antigen which is related to virulence and is common to both hæmolytic and non-hæmolytic streptococci.

SERUM THERAPY OF TYPHOID FEVER

The value of antityphoid sera in the treatment of typhoid fever has been and still is a matter of controversy (see Petrie [14]). The view was even held that through their lytic action on the bacteria such sera might be harmful to the patient, since the endotoxin is suddenly liberated without being neutralised.

The potency of the Vi antibody in protective action against infection with the highly virulent type of *B. typhosus* (Table IV.) and the definite neutralising effect of the O antibody on the so-called endotoxin (Table VI.) seem to justify the expectation that a serum containing both these antibodies will prove to be of value in the treatment of typhoid patients. It has been shown in this paper that the reactions between the two kinds of antigen and antibody take their course independently of each other and that there is no summation of the effect of the two reactions. The therapeutic serum should, therefore, contain effective amounts of each of the two antibodies, which are amenable to quantitative estimation by both in-vivo and in-vitro methods.

Horses are now being immunised at the serum department of the Lister Institute and it is hoped that a supply of the serum will shortly be available for experimental and clinical trial.

Summary

The factor present in virulent strains of *B. typhosus* and responsible for their virulence and inagglutinability is an antigen.

This antigen is separate and distinct from the O and H antigens of *B. typhosus* and renders the O antigen resistant to the action of the O antibody.

The symbol Vi (referring to virulence) is suggested for this antigen and the corresponding antibody.

The Vi antibody is demonstrable by agglutination and absorption tests; its in-vitro titre is comparatively low.

Active and passive immunisation disclose the powerful protective action of the Vi antibody.

The O antibody, which is known to exert bactericidal and opsonising effects, also neutralises the endotoxin of *B. typhosus*, whereas the Vi and H antibodies are incapable of this action.

The bearing of these facts on the theory and practice of antityphoid inoculation and of the serum therapy of typhoid fever is discussed.

THE ADMINISTRATION OF PARALDEHYDE BY THE RECTUM

AS A PRELIMINARY TO GENERAL ANÆSTHESIA

BY J. R. M. WHIGHAM, M.C., M.S. Lond., F.R.C.S. Eng.

SURGEON, ST. ANDREW'S HOSPITAL (LONDON COUNTY COUNCIL)

So widespread is the dread of anæsthesia induced by what are still the ordinary methods that it is almost a commonplace to hear a patient protest before operation that it is not the actual operation that he or she fears but the anæsthetic. Latterly, through the more general use of basal narcotics, much has been done all over the world to eliminate this dread, and the purpose of this paper is to record briefly the results of an extended trial of one such narcotic at St. Andrew's Hospital.

Out of the many drugs at our disposal we looked for one which was easy to administer, was comparatively non-toxic and, at the same time, constant in *its action*; paraldehyde seemed to fulfil these conditions best. Paraldehyde $(CH_3CHO)_3$, an ethane[1] derivative, is a product of the polymerisation of acetaldehyde (CH_3CHO), and it is classed with avertin (tri-brom. ethyl alcohol CBr_3CH_2OH) and chloral $(CCl_3CH(OH)_2)$ as an hypnotic. It is a *colourless* liquid, soluble in water to the extent of 1 in 10, more soluble in ether, and said to have an unpleasant ethereal odour, though this latter property has not proved a disadvantage in practice, either to the patient or his attendants. Though it acts by depressing the cerebral cortex, there appears to be a safe margin between hypnosis and medullary depression. It is excreted mainly by the lungs and kidneys. Death is caused by respiratory failure. A case is recorded where as much as two ounces were given by the mouth and only prolonged sleep resulted. It was recommended by Cervello as long ago as 1883. Its pharmacological antidotes[2] are picrotoxin, coriamyrtine, and camphor—stimulants to the cerebral cortex.

Our procedure is as follows:—

The patient is prepared for operation in the ordinary way. When considered unnecessary the enema is omitted. (In our early cases it was thought that there was a tendency on the part of the patient to return the paraldehyde solution when an enema had been given previously. This may have been due to the solution itself, which has since been modified slightly.) Rectal irritation, when present, may be allayed by a chloretone suppository (grs. 10), though only in exceptional cases is one required. Our rule is to give one drachm per stone of the patient's body-weight in twelve ounces of saline. It appears, however, that patients with blood pressures on the low side require proportionately lower dosages. To overcome the burning sensation complained of in some cases gum acacia has been added to prevent the tendency of the drug to come out of solution and irritate the mucous membrane of the rectum. Four grains of the powdered gum acacia are added for every ounce of saline used.

The solution, at body temperature, is given by the rectum 1½ to 2 hours before operation, very slowly by funnel and catheter, with the patient lying on the left side and the buttocks slightly raised. During the administration, which occupies 30 to 40 minutes, the ward is kept as quiet as possible. The patient comes under the influence of the drug in about 25 to 45 minutes, sleeping quietly and quite unconscious of his surroundings. In this condition he is transported to the theatre. Induction is accompanied by very little excitement, except for occasional talkativeness. The rate of induction and depth of narcosis resulting from a given dose of the drug vary slightly in different patients, and so it is as well to begin inducing early to be on the safe side. If anything, the condition of the patient is all the better for his being kept a short time in the ward before proceeding to the theatre. During this time he should be kept under observation, though no respiratory or other difficulties are to be expected; he lies quietly on his left side, the limb reflexes are lost and the corneal reflex depressed; the cough reflex is still present; the pupils are contracted. Several patients can be treated together by the ward staff, ready to proceed in their turn to the operating theatre. An injection of atropine is usually given half an hour before operation.

The blood pressure taken before the administration of the drug and again in the theatre showed an average fall of systolic pressure of 22 mm. (varying from 0–50 mm.) and an average fall of pulse pressure of 9 mm. (varying from 0–20 mm.). The pulse-rate is not perceptibly altered. It has been our practice to continue anæsthesia with gas-and-oxygen and, if necessary, a minimal amount of ether in addition. This latter may be required for the skin incision, the peritoneal incision, or during dragging on the mesentery for any reason, though a surprisingly small amount is required for full surgical anæsthesia. It is at these moments that the coöperation of the anæsthetist is so important to ensure success. When relaxation has been obtained ether can usually be discontinued. De-etherisation can be brought about at the end of the operation by the use of 5 or 10 per cent. carbon dioxide oxygen inhalations. The absence of bronchial secretion makes the response to inhalation methods all the more delicate, and the breathing is devoid of that mucous rattle which is frequently heard when inhalation methods alone (especially ether) are employed. The colour of the patient is sometimes sallow after the paraldehyde has been given, but quickly improves when gas-and-oxygen is administered, and then usually remains good throughout the operation. On return to the ward the patient recovers consciousness in one-half to two hours, depending on the amount of additional anæsthetic used at operation, though drowsiness may continue for 6 to 14 hours.

[2] Meyer, H. H., and Gottlieb, R.: Experimental Pharmacology, translated from the German by V. E. Henderson. Philadelphia, London, and Montreal, 1926.

During unconsciousness the relaxed jaw and tongue require watching, and Hewitt's airway or swabbing of the pharynx is useful in cases likely to suffer respiratory difficulty, but no more than ordinary care is demanded in most cases. The patient, once roused, can be put in Fowler's position or on the left side, and is then allowed to go off to sleep again—which he generally does. A rectal washout on return from the theatre is not necessary. *Post-operative morphia may be dispensed with in* some cases. Post-anæsthetic vomiting is slight or absent. *Hiccough sometimes occurs, but is well controlled by the* inhalation of 5 or 10 per cent. carbon dioxide, and is of no serious consequence.

To avoid any tendency to atelectasis it has been our practice to give 5 per cent. carbon dioxide in oxygen as an inhalation for a short while every four hours for the first day. On the day after the operation there is diminished sensibility to pain and less restlessness, factors which *favour post-operative healing.*

It is our opinion that post-operative pulmonary complications — e.g., bronchitis and bronchopneumonia—are more frequently absent and, when they occur, less severe than when ordinary inhalation methods are used, although it is not easy to obtain figures to substantiate this. It might be argued that the shallow breathing would predispose to these difficulties, but even without the excessive use of carbon dioxide inhalation this has not, in our experience, proved to be the case.

In all, 200 *consecutive* surgical cases have been anæsthetised by this method. In this series there were nine deaths, but these could in no way be attributed to the anæsthetic. The advantages of the method are obvious. The excitement of an operation and the mental strain of the events which lead up to it *are removed ; the patient goes to sleep in bed, not* realising in many cases that the operation has taken place and the ordeal is over, and convalescence is in consequence easier and less disturbed. From the nursing point of view, the time lost before operation is more than compensated by a quicker convalescence. There is also a definite saving of time in the anæsthetic room between operations. *The drug itself is consistent* in its action and requires no complicated technique for its administration. *It has no depressing effect* on the heart. Children take proportionate doses well, the aged and very toxic patients not so well; in the latter there is *a tendency* for the paraldehyde solution not to be well tolerated. In cases of colitis and ulceration of the rectum the drug is definitely contraindicated. Its use is obviously less practical in surgical emergencies. In cases where, for some reason or other, it was possible to give only a small dose, no harm was done and anæsthesia was *induced by* the ordinary methods. In one case of severe jaundice, with marked hepatic insufficiency, the drug was given with no harmful effect. In operations about the head and neck freer surgical access is possible, and *in gynæcological operations (especially for perineal* repairs) healing is favoured by the post-operative calm.

I have been fortunate, in my endeavour to give this method a trial, to be associated with Mr. J. M. Milloy, Dr. Joyce Morgan, and Dr. Catherine Lendrum, who have afforded me every assistance. To our two surgical sisters, Sister Jane Lynn and Sister Jessie McGregor, without whose coöperation success could not be attained, I am greatly indebted for the painstaking care with which they have tended the patients in the wards. *In this short series we have all (patients, medical and nursing staff alike) been much impressed with the advantages of the use of this drug, so much* so that it seems likely to establish itself as a routine method of induction for all ordinary surgical cases in the hospital.

INTESTINAL OBSTRUCTION CAUSED BY IMPACTED GALL-STONE

DIAGNOSIS BEFORE OPERATION

By Eugene Rosenthal, M.D.

LECTURER IN THE ROYAL UNIVERSITY, BUDAPEST, HUNGARY

Intestinal obstruction caused by gall-stones is rare. Adams and Cassidy[1] found it in 6 cases only out of 500 operated on for intestinal obstruction in St. Thomas's Hospital during a period of twenty years. Because the condition is so rare and because the symptoms *require urgent surgical intervention,* the patient is usually operated on before the cause of *the ileus is diagnosed. This may account for the* fact that gall-stone obstruction is usually only diagnosed at operation. In a recent case under my care it was possible to make an exact diagnosis beforehand.

A woman, aged 45, was seized with severe colicky pains in the middle of the lower abdomen, which lasted for about an hour. On the next evening the pain reappeared and was more violent, and she vomited. The *pain was so bad that she was given a hypodermic injection* by her family doctor. As he had found diabetes eight weeks previously he also gave her a dose of insulin. On the next day she had a good deal of meteorism but passed very little gas, and repeated enemas only yielded a small quantity of brownish fluid. The third and fourth days of her illness were chiefly characterised by bilious vomiting. The temperature throughout was normal.

I saw her on the fourth day. She did not give the impression of being seriously ill; her colour was fresh, her tongue moist, and she gave a calm and comprehensive account of herself. No abnormality of the chest organs was found except an elevated but freely moving diaphragm. The abdomen was markedly distended and the umbilicus retracted. There was no abnormal dullness in the lower *parts of the abdomen and the liver dullness was normal.* Nor was there any tenderness or muscular contraction. Nevertheless the pulse-rate was about 120 with a normal temperature, so that the diagnosis of small intestine obstruction was hardly in doubt. Suspicion of gall-stones arose on account of the diabetes, and after repeated inquiries the patient admitted that she had had gastric trouble four years previously for which a cholecystography *had been performed by the intravenous method* but the gall-bladder had not been seen.

A radiogram showed dilated intestinal loops (Fig. 1) which located the obstruction in the small intestine. A

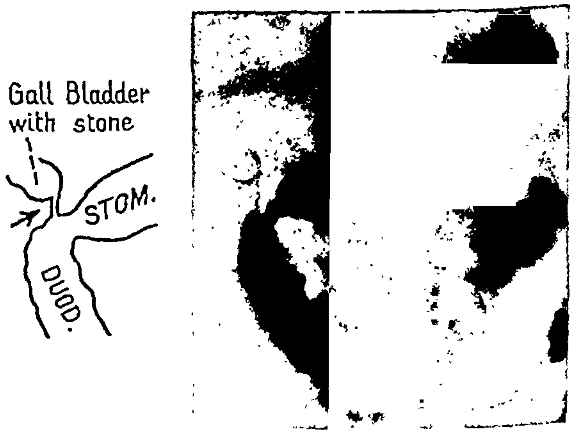

FIG. 2.—Radiogram showing the communication between gall-bladder and duodenum.

---

[1] Adams, T. E., and Cassidy, M. A.: Acute Abdominal Diseases, London. 1913, p. 146.

arium meal was then ad- ninistered and was shown to ass through a canal, 3 cm. ong and only a few milli- netres wide, running upwards nd outwards from the upper art of the duodenal bulb and nding in a somewhat larger rgan (Fig. 2) which seemed o be the gall-bladder. The arium also showed the di- ated intestinal loops. This bnormal passage appeared o be the canal through which he stone had passed and, lespite the absence of gastric nd gall-bladder pain, the liagnosis of perforation of a all-stone into the duodenum vas confidently made. The violent pains in the first days of the illness had been caused by impaction of the stone in the lower loops of the ileum (Fig. 3). Dr. D. Klimkò operated and found a gall-stone the size of a walnut (5 by 3 cm.) in the lower part of the ileum. The intestine was dilated above it and collapsed below it. There was peritonitis from which the patient died two days later. At autopsy a second stone was found in the gall-bladder and, buried in adhesions, the canal through which the first stone had passed into the duodenum.

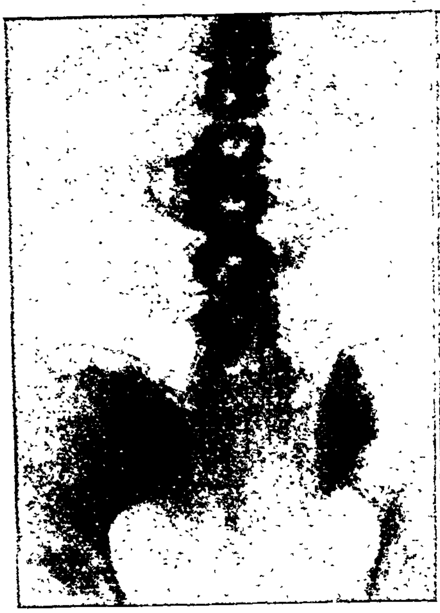

FIG. 1.—Dilating loops of the small intestine.

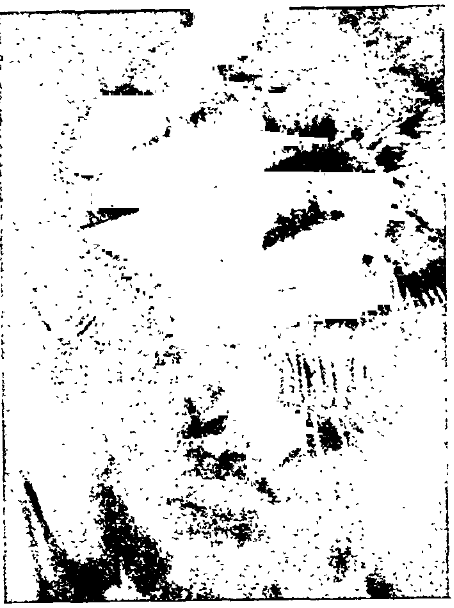

FIG. 3.—Showing the stoppage at the lower loops of the ileum.

The two facts which emerge from this case are: (1) a comparatively large stone may penetrate into the duodenum without causing pain; (2) pre-operative examination revealed the exact diagnosis and demonstrated the importance of carrying out the plan of examination suggested by me some years ago.²

STONE IN THE LOWER URINARY TRACT IN INDIA

EXAMPLES OF MULTIPLE CALCULI

By Rufus C. Thomas, F.R.C.S. Edin.

CHIEF MEDICAL OFFICER TO HIS LATE HIGHNESS THE MAHARAJAH JAMSAHEB OF NAWANAGAR

India may be looked upon as the home of urinary calculi. Stone is one of the commonest conditions with which a surgeon is called upon to deal. The following notes are prompted by an experience over a period of six years in a part of India where stone was very prevalent. The number dealt with in that time was about 250.

By far the greater number occurred in males above the age of 8 years. It was, however, quite a common thing to operate on much younger children. The youngest child I operated upon was 6 months old and had a stone the size of a hazel-nut. It must have taken several months to reach that size. I believe children of much smaller age have been dealt with by others. The proportion of females was small, and those operated upon were chiefly below the age of puberty. The reason for this is obviously the ease with which small stones can be passed through the female urethra. Two or three cases of stone in the prolapsed bladder in subjects of procidentia occurred, the stones being removed through the anterior vaginal wall. In one old lady a large stone was removed per urethram, after dilatation with Hegar's dilators. A good many stones impacted in the male urethra were dealt with, the greater number being held up at the commencement of the penile urethra. A small number of prostatic stones were met.

The commonest stone was the hard, smooth, oval urate, of which two were often found, and sometimes three. Next came the phosphatic. Both these types were often very large. The mulberry calculus was always small, on account of the pain and vesical irritability it caused, so that the patient early sought advice. Hæmaturia and pain at the end of micturition was the usual complaint in mulberry calculus. The other patients complained more of frequency, sudden cessation of the urinary flow, and a feeling of heaviness in the bladder or perineum. Pain only became a predominant symptom when cystitis was present, or a stone became impacted in the prostatic urethra.

A very striking thing about most of the cases was the long time over which symptoms were endured before advice was sought. Some of the adults, judging by the size of their stones, must have been suffering for years. This is also borne out by the multiplicity of stones in some cases. Several cases of long standing had to have a bladder drainage on account of the pronounced degree of cystitis. In one instance, the bladder was found to be so sloughy that it was impossible to stitch it up, each stitch cutting out as soon as inserted.

This was a Hindu about 30 years of age. He had three very large stones, and was in great pain on admission. He was running a high temperature, and was so ill that I was for a day or two doubtful whether he would stand an anæsthetic, and gave him morphia for two days to give him some sleep. I removed the stones on the third day, leaving a suprapubic tube in to drain the bladder. In spite of this he died about eight days later of septicæmia. This was the only fatality out of the total number of cases, and was not to be wondered at, in view of his bad condition.

TREATMENT

I removed every stone by the suprapubic route except those in the prolapsed bladder and the impacted

---

[2] Rosenthal, E.: Monats. Ungar. Med., 1930, iv., 59.

urethral stones. Many of the stones were very large, and therefore not suitable for lithotrity. Many patients had two and even three stones, and lithotrity would have been a very long operation. Cystitis was quite common. Lastly, and no doubt this reason weighed very largely with me, the removal of a stone or stones by the suprapubic route never took more than 20 minutes, and was often completed in ten minutes, thus saving valuable time. And there appeared to be no more risk. It had the added advantage of permitting direct inspection of the bladder wall. The average time spent by the patient in hospital was about 15 days. Most of the patients were cultivators, who came in in the slack season when there was very little work to be done in the fields, and a fortnight meant nothing to them. Time is of very little account in India. All cases were put on to a mixture of hexamine and acid sodium phosphate, grs. 10 each, for three days, and their stones removed on the fourth day.

The operative technique consisted of the usual subumbilical incision and separation of the recti and pyramidalis, which were retracted by an assistant. The peritoneum was then wiped upwards off the bladder, which was opened below it. After removal of the calculus the bladder was swabbed dry, then closed by a running suture of No. 0 catgut from above downwards, taking mucous membrane and muscle together. This suture, after knotting below, was brought up again as an invaginating suture and tied with the original end. Fascia was closed with No. 1 catgut in children and No. 2 catgut in adults. The skin was closed with Michel's clips. A catheter was passed and strapped in in the usual way and retained for nine to ten days. A few cases developed a leak through the incision, due, I am sure, to removal of the catheter a day or so too early. This cleared up in a short time after replacing the catheter.

The following cases are quoted, as they all have some points of interest, and serve to show the length of time during which the Indian patient will put up with much discomfort before seeking advice.

CASE 1.—This must be, I think, something of a record. An old man was admitted with some pain on micturition and slight pain in the lower abdomen. Palpation revealed a mass in the subumbilical region, tender on pressure. A sound could only be passed into the bladder with difficulty. Radioscopy showed a hazy, ill-defined shadow. On opening the bladder it was found to be absolutely full of small stones, the largest not being bigger than a small nut, and the greater number being the size of a small pea or less. The opening in the bladder was enlarged and the stones removed by the aid of a spoon. There were found to be 635 stones of all sizes. The bladder was entirely filled with them, and there could have been very little room for urine. How many years the old man had taken to accumulate such a vast quantity can only be left to the imagination. The bladder was closed in the usual way, and recovery was uneventful.

CASE 2.—A Hindu, complaining of great pain and difficulty in passing urine, showed marked priapism, and a sound could not be passed, being held up in the prostatic urethra. Radioscopy showed five large stones all lumped together. On opening the bladder two large stones were removed. The prostate was found to be very much enlarged, and on pushing the finger into the prostatic urethra a mass of stones was found to be impacted in it. All efforts to dislodge one of them with the finger failed, so an incision was made forward through the prostatic tissue, and three very large stones evacuated. They must have been present for many years. The cavity left in the prostate after their removal was big enough to put a small orange into. Why the man should have delayed so long before seeking advice is a mystery.

CASE 3.—A Hindu came complaining of frequency of micturition. The passage of a sound revealed a stone in the bladder. I had made it a rule to radiograph the whole urinary tract in all cases of stone, and this patient was found to have a stone in the right ureter, about four inches above the bladder. This stone appeared to be about the size of a small hazel-nut. The stone in the bladder was removed first and the bladder closed in the usual way. The peritoneum was then pushed off the right pelvic wall and the ureter exposed. In its course was found an indurated mass the size of a walnut at the level of the pelvic brim. The mass was not fixed, but could be raised slightly by the fingers. It was incised and a pear-shaped stone removed. The opening in the ureter was stitched over, a small tube placed in position through a stab-wound in the loin, and the abdominal incision closed. The tube was left in for 48 hours, but there was no drainage from it, and on its removal the wound closed without any trouble. The patient left hospital three weeks later quite well. This patient gave no history of renal or ureteric pain, nor was there in his history anything to lead one to suspect ureteric calculus. Had it not been for the routine radiography of the upper urinary tract the stone would have been missed altogether.

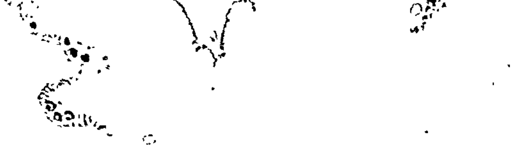
The above cases will serve to show that stone in the bladder may not be quite so simple as it sounds, and that a radiogram of the upper urinary tract is worth making in all cases. The temptation to be satisfied with the discovery of a bladder stone by the aid of a sound is very great, and one is apt to forget that further trouble may be lurking, unsuspected, in the higher regions.

ENTEROGENOUS CYST OF THE ILEUM IN AN INFANT

By A. L. D'ABREU, M.B. Birm., F.R.C.S. Eng.

ASSISTANT IN THE SURGICAL UNIT OF THE WELSH NATIONAL SCHOOL OF MEDICINE, THE ROYAL INFIRMARY, CARDIFF

CYSTS lined by intestinal epithelium wherever found in the abdomen must be derived from gut (Evans[1]). They are now described as developmental enterogenous cysts. Their congenital origin is indicated by the valuable work of Lewis and Thyng,[2] who found that diverticula of the small intestine of the pig embryo occurred with remarkable constancy and arose from the canalisation of solid bud-like outgrowths from the bowel. Most of these completely disappear. Rarely they persist as congenital diverticula or become



The epithelial-lined cyst encircled by smooth muscle and not in communication with the bowel lumen. The intraluminary projection of the mass is covered by normal mucous membrane.

---

[1] Evans, A.: Brit. Jour. Surg., 1929, xvii., 37.

[2] Lewis, F. T., and Thyng, F. W.: Amer. Jour. Anat. 1907, vii., 505.

sequestrated from the bowel lumen to form cysts which may be submucous, intermuscular, subperitoneal, intramesenteric, or omental in position. These two observers noted the same process occurring in the rabbit and in the human embryo: with the exception of cæcal enterocystomata this developmental curiosity is not met with in the large bowel.

A male child of 3½ months was admitted to the Cardiff Royal Infirmary on Jan. 11th, 1934. On the previous day vomiting had occurred and there had been no action of the bowels. On the day of admission the child constantly cried out in pain and passed blood and slime from the rectum. A history of constipation since birth was elicited. On examination the child was feeble, pale, and wasted. Temperature 98·4° F., and pulse 132. A hard oval lump could be felt in the right iliac fossa; blood and mucus were present in the rectum on digital examination. With such findings a diagnosis of intussusception was made.

Under general anæsthesia, through a right paramedian incision, a tumour was felt projecting into the lumen of the ileum three inches from the ileocæcal valve, and quite occluding the gut; proximal to this the small intestine was distended. By a longitudinal incision into the bowel a circular tumour covered by mucous membrane was excised together with a portion of the gut from which it arose; the incisions were closed in two layers. After progressing satisfactorily for two days the child collapsed and died. At the post-mortem no obvious cause of death was found; apart from hypertrophy of the bowel above the area where the tumour had been, no other abnormality was found in the abdomen.

The accompanying Figure represents the tumour after section. In the centre of whorls of smooth muscle lay a cyst containing yellow glairy fluid and seen on microscopical examination to be lined in places by typical intestinal epithelium. Part of the wall was denuded of epithelium, due perhaps to atrophy caused by intracystic pressure.

The case is one of intermuscular enterogenous cyst causing intestinal obstruction in an infant and simulating very closely intussusception.

I am grateful to Prof. A. W. Sheen, director of the surgical unit of the Welsh National School of Medicine, for permission to publish this record.

REVIEWS AND NOTICES OF BOOKS

Diseases of the Chest

And the Principles of Physical Diagnosis. Fifth edition. By GEORGE WILLIAM NORRIS, A.B., M.D., formerly Professor of Clinical Medicine in the University of Pennsylvania; and HENRY R. M. LANDIS, A.B., M.D., Sc.D., Professor of Clinical Medicine in the University. With a chapter on the Transmission of Sounds through the Chest, by CHARLES M. MONTGOMERY, M.D., formerly Physician to the Phipps Institute, Philadelphia; and a chapter on the Electrocardiograph in Heart Disease, by EDWARD B. KRUMBHAAR, Ph.D., M.D., Professor of Pathology, University of Pennsylvania, School of Medicine. London and Philadelphia: W. B. Saunders Company, Ltd. Pp. 997. 50*s*.

THIS exhaustive treatise on the physical diagnosis of the heart and lungs in health and disease holds a high place in the esteem of student and practitioner. Though intended primarily for the American student, the work requires no introduction anywhere among English-speaking peoples. The fifth edition reproduces the essential features of former ones, but many sections have been revised and new material has been added; for example, an account of the use of the bronchoscope in the diagnosis of disease of the bronchi and lungs.

The authors rightly insist that the facilities now available for specialised and laboratory methods of diagnosis should not be made an excuse for neglecting well-established physical methods. But radiology, a science unknown when the classical methods of physical examination were devised, has shown their limitations and provided for many types of disease a far more accurate means of determining the condition of structures within the thorax. It is a mistake to lead the student to expect to obtain more information from the results of auscultation and percussion than these somewhat crude expedients can provide. For example, it is difficult to believe that the most skilful percussion would indicate the shape of the heart as it is revealed by radiological examination in the various conditions of valvular disease (p. 242). The over-elaboration of percussion leads to waste of time, disappointment, and consequent depression, and withdraws attention from a more valuable general consideration of the patient's condition.

The number and excellence of the illustrations is praiseworthy. The photographs of diseased organs in situ are especially good. The lights and shades are so well reproduced that by merely looking at a plate through a roll of paper an almost stereoscopic view of the parts is obtained, and the practitioner who lacks time to study the text could learn much from a careful examination of the illustrations alone.

Atlas of External Diseases of the Eye

By HUMPHREY NEAME, F.R.C.S., Hon. Ophthalmic Surgeon, Royal London Ophthalmic Hospital. London: J. and A. Churchill. 1934. Pp. 110. 15*s*.

THESE 51 coloured plates are all well drawn and give excellent pictures of the conditions depicted. Several are from the author's own patients and have been previously published in the "Handbook" which he wrote in conjunction with Mr. Williamson-Noble. They represent typical examples of common conditions with a few uncommon ones—e.g., a remarkable case of congenital cavernous angioma of the sclerotic. All the drawings were made in the drawing department of Messrs. Theodore Hamblin. Each is accompanied by a short summary of the disease illustrated with the usual treatment.

Introduction to Study of the Nervous System

Second edition. By E. E. HEWER, D.Sc., and G. M. SANDES, F.R.C.S., M.B. London: William Heinemann, Ltd. Pp. 147. 21*s*.

THIS book, whose first edition was favourably reviewed in these columns, serves as an introduction, for the purposes of the student, to nervous anatomy and physiology. The former is treated by descriptive methods bearing chiefly on nerve-cells and tracts, and is illustrated by a large number of unusually simple and clear diagrams, most of them coloured. A few pages are also assigned to the experimental pathology of the neurone, and to the normal histology of neural and interstitial tissue. The neurophysiology is mainly of the applied order, though not exclusively; the normal paths of motion and sensation, and of the special senses, are concisely described, and the results of functional interference briefly set forth. Reflex action, conditioned reflexes, motor coördination, and the functions of the autonomic system form the subjects of other chapters. As is remarked at the outset, the authors have sought to avoid unconfirmed and controversial statements, with consequent gain to the student. The value of the work is enhanced by a series of tables giving, for instance, the constitution of the cranial nerves, the afferent and efferent sympathetic supply of different organs and tissues, the contrasted effects of upper and lower motor neurone lesions. The least satisfying part of the book comes at the end, with the heading of Notes on Certain Pathological Conditions. For some reason not immediately apparent the choice has fallen on the curious medley of hemisection of the cord, complete section of the cord, aphasia, and nystagmus. To the last of these eight lines only are allotted.

A Text-book of Gynæcology

For Students and Practitioners. Third edition. By JAMES YOUNG, D.S.O., M.D., F.R.C.S.E., F.C.O.G., Gynæcologist, Royal Infirmary; Physician, Royal Maternity and Simpson Memorial Hospital, Edinburgh. London: A. and C. Black, Ltd. Pp. 411. 16*s.*

THIS book is primarily intended for the student, and will be found to cover the ground adequately. Dr. Young has not wasted space on detailed descriptions of the technique of operations, such as hysterectomy, but gives sufficient detail to enable the student to understand what is being done. The work has been thoroughly revised, and new chapters have been introduced describing the recent advances in our knowledge of the hormones of the ovary and the anterior pituitary gland, and giving an excellent account of the functions of the hormones as at present understood. The chapters on dysmenorrhœa, amenorrhœa, and uterine hæmorrhage have also been rewritten. A new chapter of special interest is that on pain in gynæcology. It will be of great use to the practitioner in the diagnosis of the origin of pelvic pain. A slight error has crept into the section on vaginitis, where 2½ per cent. picric acid in water is recommended for treatment. Picric acid is soluble in water to the extent of only 1 part in 90.

The book gives throughout a well-balanced account of pathology, diagnosis, and treatment, and is illustrated by a number of clear drawings and photographs.

A Handbook of Filterable Viruses

By R. W. FAIRBROTHER, M.D., M.R.C.P., Lecturer in Bacteriology and Assistant Director of the Public Health Laboratory, Manchester University. London: William Heinemann, Ltd. 1934. Pp. 204. 7*s.* 6*d.*

Dr. Fairbrother's small volume is welcome, for the need of a reliable introduction to this important subject has been felt. It is clearly written, free from all unnecessary detail, and the many points of controversy are presented in an unbiased manner. The first half of the book is devoted to questions of a general nature, cultivation and microscopy, epidemiology, immunity, and the nature of filterable viruses. Then comes the description of the individual viruses causing disease in man grouped as accepted, probable, and possible virus diseases. No other classification is attempted; a wise precaution. In view of Mervyn Gordon's work one might ask why it is that lymphadenoma is not mentioned along with the other "possibles"; and lymphogranulomatosis inguinale is surely worthy of inclusion. One or two statements are open to question. The assertion, for instance, that there is every indication that the viruses are a very heterogeneous group is hardly warranted, and the same applied to the statement that the inoculation of a single large dose in a susceptible animal is the severest test for the presence of living virus. However, these are minor points which do not seriously detract from a book which we commend to the notice of students of medicine, both undergraduate and postgraduate.

An Introduction to Practical Bacteriology

A Guide to Bacteriological Laboratory Work. Fourth edition. By T. J. MACKIE, M.D., D.P.H., Professor of Bacteriology, University of Edinburgh; and J. E. MCCARTNEY, M.D., D.Sc., Director of Research and Pathological Services, London County Council. Edinburgh: E. and S. Livingstone. 1934. Pp. 504. 12*s.* 6*d.*

THIS excellent little book has been enlarged and amplified but has not yet reached clumsy proportions. As an introduction to practical bacteriology it has few rivals. The technical methods described are of the best and the accounts of them are extremely clear. The description of various organisms, including protozoa and filtrable viruses, though highly compressed, are excellent and will fulfil all the needs of the elementary student if he has pursued his practical work seriously. We trust that the authors will not be tempted to make any further additions, since a book of this sort can easily be spoilt if it grows too big.

Spinal Anæsthesia

By GEORGE RUDOLPH VEHRS, M.D. London: Henry Kimpton. 1934. Pp. 269. 21*s.*

IN this book the author attempts to present a comprehensive account of spinal anæsthesia with novocain. In the early chapters we find descriptions of the anatomy and physiology of the subarachnoid system of spaces and circulation, and consideration of the chemistry and pharmacology of anæsthetic agents in addition to the description of ordinary anæsthetic technique. A number of experiments have been made on dogs, novocain being injected into the cisterna magna; and the conclusion arrived at was that the apparent immunity of the great bulbar centres when not too large a dose is thus administered is due to dilution of the anæsthetic drug by the large volume of cerebro-spinal fluid in this situation. Dr. Vehrs is an enthusiastic advocate of spinal anæsthesia and sometimes is not very judicious in his statements; for example: "it is agreed that spinal analgesia is, in proper hands, safer than other types of anæsthesia" . . . "a discussion of an over lowering mortality-rate is not of material value except to recommend the procedure." He offers interesting hints on technique, among which are the advocacy of lateral spinal puncture and the maintenance of the spinal canal exactly horizontal by keeping the patient on his side for some minutes after injection to fix the novocain in the nervous tissue. Spread of the drug in the canal is held to be due to gravity diffusion alone, no other factors being considered at all. Dr. Vehrs believes it is possible to produce sensory nerve-block at will without any motor paralysis, and he describes a technique designed to this end; the insistence on the need for personal skill and experience of the operator is too great to be altogether convincing. The technique of a simple technical procedure of this sort should be easy to acquire, and its success should be assured.

BRITISH MEDICAL ASSOCIATION

MEETING IN BOURNEMOUTH

PROCEEDINGS OF THE REPRESENTATIVE BODY

THE first business with which the Representative Meeting of the British Medical Association is concerned year by year is a formal motion from the chair "that the return of election of representatives of constituencies . . . be received." This year murmurs of "agreed" were interrupted by excited cries of "No, no," while Dr. St. G. B. DELISLE GRAY (Brighton), leaping to the platform, drew attention to the sad case of Dr. R. A. Wilson of Guernsey. It appeared that Dr. Wilson, the hon. secretary of the local division, had for many years represented Guernsey, but that since the amalgamation last year into one division of Guernsey, Alderney, and Jersey, the other two Channel Islands had a voice in the election. The voice of Jersey had been raised in protest against Dr. Wilson, but no other nomination had been made in his stead, and Dr. Wilson stood, a Peri at the gate, awaiting a ruling. It took the best part of an hour to sort out the issues raised by this embarrassing contretemps, for while the sympathy of the meeting was clearly with Dr. Wilson, after his long journey to be with them, it was equally clear that representatives must be elected by the whole of a constituency and not at the discretion of the meeting. An amendment authorising Dr. Wilson to be present without the right to speak or vote was carried, and in the course of the day he was restored to full potency by a telegram from Jersey, in response to a final appeal, accepting him as a "temporary" representative.

Another point of procedure was involved in a motion by Brighton, supported by Kensington and Cambridge, and carried by a substantial majority, that spontaneous motions by divisions and branches which did not arise out of the Council's report should be taken early on the morning of the last day of the meeting, instead of being left to the end and hurriedly disposed of.

The chairman, Dr. E. K. LE FLEMING, whose appeal for support in expediting business had so far met with a poor response, then managed to get through a useful batch of motions with little delay. Dr. S. WATSON SMITH, hon. physician to the Royal Victoria and West Hants Hospital, was elected president of the Association for 1934–35—Mr. F. W. RAMSAY having been unable to serve by reason of ill-health——and Sir RICHARD STAWELL of Melbourne for 1935–36.

Research Scholarships and Grants

In connexion with the finance of the Association, Sir EWEN MACLEAN proposed and Sir CRISP ENGLISH seconded a motion that the Council should consider the desirability of increasing the amount allocated to research scholarships and grants. The criticism that the Association was concerned mainly with the cash basis of the profession was known by all present to be without foundation, but though much was spent indirectly not more than £1000 was directly allocated to research, and a more generous policy in this respect would be desirable. Mr. BISHOP HARMAN, as hon. treasurer, pointed out the enormous indirect contribution to medical science made by the Association, notably in B.M.A. lectures, in reports of ad hoc committees (such as that on arthritis), in the library, in the two special scientific journals, published at a loss, and, most of all, in the *British Medical Journal*. The motion was lost, but Sir Ewen remained unconvinced.

Medical Education

In presenting the report of the committee on medical education for general approval, Sir HENRY BRACKENBURY pointed out that an interim report which was now amplified had been before the meeting last year and no objections had then been made to its main propositions. It had since received a considerable measure of general endorsement, with only one dissentient. No stereotyped system of medical education was contemplated; provided a minimum was fixed there was ample room for differences of method and variety as between different schools. It was sought to raise somewhat the scientific status and general educational equipment of entrants to the profession; to design a coördinated course rather than separate blocks of study; to direct attention to health, its preservation, perfection, or restoration, and not to disease, so that a patient would be regarded as a person to be restored to the normal, if possible, and not as "an uninteresting vehicle containing some fascinating disease processes." The time of registration should be at the point where the study of human anatomy and physiology is systematically begun, and the student should previously have passed an examination such as the higher school certificate examination of the universities, taking subjects of general educational value as well as chemistry, physics, and biology. Normally the age of registration would not be below 18, but exceptional students, who had passed the necessary examinations, would be allowed to register at 17. A feature of the scheme was the insistence on a period of from six to nine months after the main part of the final examination had been passed before full licence to practise independently was granted. This period could be spent in a resident appointment or as a clinical assistant in a hospital, as a pupil assistant to a general practitioner or a medical officer of health, or in regular attendance at hospital practice at a medical school. The final examination would then be completed by a clinical and oral test which could be taken 57 months after registration, so that the length of the present curriculum need not be exceeded.

On getting the assurance of Sir Henry Brackenbury that a covering letter would be sent with the report intimating that only general and not necessarily detailed approval had been given by the various branches and divisions, Sir ROBERT BOLAM (for Newcastle) withdrew a cautious amendment to the motion recommending the approval and distribution of the report. Mr. ERNEST WARD (for Torquay) felt doubtful of the merits of a "decree nisi" which had to wait six months for confirmation (for example, could its holder become a locum?); but was informed that study of Sections 43 to 46 of the report (*Brit. Med. Jour.* Suppl. of April 21st, p. 193) would convince his division of the latitude of responsible work contemplated for the practitioner delivered into the world but still unregistered, and withdrew an amendment that this clause should be referred back to Council. The same fate, by permission, befell an amendment by Dr. HELEN LUKIS (for Kingston), which drew attention to the danger of allowing a student to qualify after administering only ten anæsthetics. In these days of varied drugs and methods and mechanisation of apparatus she felt that this number was quite inadequate, but readily consented to regard this as one of the small rocks which should not wreck the ship.

Sir Henry then proceeded, with the skill of an experienced pilot, to steer it to port through more formidable barriers sighted by Dr. Hawthorne, Dr. M. Manson, Mr. McAdam Eccles, and Dr. A. Gregory. Dr. MANSON regretted, among other omissions, the absence of provision for a one portal entry to the profession and of intelligence-quotient tests for students. Dr. GREGORY thought that the proposed additions to the curriculum, notably instruction in genetics, growth, minor operations, and the psychoneuroses, and additional clinical experience would more than cancel the relief offered from dissecting every part of the body or preparing histological sections. Ways in which the students' burden could be lightened were the removal of compulsory attendance at formal lectures, the diminution of time spent on major surgery, and the addition of two or three weeks to each term. Mr. MCADAM ECCLES feared that the curriculum would be increased in length, but he was convicted of an error in arithmetic, though it was admitted that part of the vacations might have to be used in work by students in the later stages of their course. Manchester had instructed Dr. Gregory to move an amendment asking the Council to urge the raising of the age of registration forthwith to 18, with the triple object of preventing the admission of immature students, of raising their standard of general education to correspond with the higher general standard among the public, and of restricting the entry to a profession which was becoming overcrowded. According to Dr. Gregory, the number of doctors on the register had risen by 19,000 between 1902 and 1932, while the population had not increased in anything like the same proportion. The effect of raising the age *forthwith* as proposed (registration not being compulsory at the present time) would, it was pointed out, defeat its own object, and even in the future Sir Henry Brackenbury was not prepared to penalise the exceptionally intelligent student by causing him to mark time between school and registration. The obvious desire of all who offered criticism of the report from various angles not to delay its circulation was a notable tribute to the wisdom of its provisions, which were duly adopted.

Ethics of Medical Consultations

The rules upon the ethics of medical consultations in private practice as redrafted were submitted for the consideration of the Representative Body by Dr. HAWTHORNE, for the Council. An amendment (for Torquay) by Mr. ERNEST WARD substituted the milder expression of "regulations" for "rules" and was lost. The first ten of the 11 rules, which were accepted and passed without comment, contain an interesting new clause—including among the circumstances under which it is especially desirable that the attending practitioner should endeavour to secure consultation "when continued administration of any drug scheduled under the Dangerous Drugs Acts is deemed desirable in the case of a person who does not need it otherwise than for the relief of symptoms of addiction." The last clause in the following proposed rule (No. 11) gave rise to keen discussion.

> The practitioner consulted shall not supersede the attending practitioner during the illness with which the consultation was concerned, nor shall he act as attending practitioner to the patient in any subsequent illness, except after an explanation given to his former colleague, unless circumstances should make this latter course impracticable.

Dr. J. T. D'EWART (for Manchester) proposed the deletion of the last eight words as giving a loophole for evasion. Dr. HAWTHORNE, as chairman of the Ethical Committee, deprecated such rigidity as the rule would then demand; the former practitioner might be retired, travelling, or even dead. The amendment was lost, as was also one by Dr. H. M. BIRD (West Suffolk) to substitute "impossible" for "impracticable," and the proposed new rules were accepted without alteration.

The following set of four rules under the heading

Other Intra-professional Obligations in Private Practice

are new in the sense that no corresponding paragraphs appear in the existing rules.

1. When a practitioner in whatever form of practice believes that a patient who requests him to give advice or treatment is not under the care of another practitioner he is at liberty to do so, unless he has previously seen the patient in consultation with a colleague or when acting as deputy for a colleague. In either of these events, while dealing with any emergency that may exist, he should forthwith explain the position to his colleague.
2. A medical practitioner, before superseding another in the care of a patient, must satisfy himself that the other practitioner has been duly informed by those responsible for the patient that his services are no longer required.
3. When a practitioner in whatever form of practice is asked for advice or treatment by a patient and has reason to believe that the patient is already under medical care, and that the request is made without the knowledge of the attending practitioner, it is the duty of the practitioner so approached to urge the patient to permit him to communicate with the attending practitioner. Should the patient refuse this proposal the practitioner is at liberty to examine the patient and to tell the patient his findings and conclusions, but he shall not accept the patient for treatment.
4. When a practitioner in whatever form of practice is requested by a patient or the patient's representatives to visit him for the purpose of giving advice or treatment, and has reason to believe that another practitioner is in attendance, it is his duty to inform the patient that he cannot attend without the presence or consent of the practitioner actually in charge of the case. If the attending practitioner, after being duly informed, declines to meet the practitioner who has been invited, and the patient or his representatives persist in the request in full knowledge of this fact, or if the attending practitioner retires from the case, it is open to the other practitioner to provide the medical care required.

In introducing them, Dr. HAWTHORNE outlined the principles which they embody. While a practitioner is within his moral and legal rights in accepting any patient, this charter of liberty is qualified by considerations in the interests of the patient. Thus, if he knows that the patient is under the care of a colleague he must beg that this colleague be informed, or must refuse to accept the patient, except of course in emergency. The patient also may seek advice where he will; he may consult several doctors on the same issue, and may desire or demand a second opinion by, or even against, the advice, or with or even without the knowledge, of his attending doctor. But the claims of courtesy between colleagues remain. Alternative policies would be (*a*) no rules at all, in the conviction that the great majority of the profession play cricket according to recognised though unwritten rules, or (*b*) the division of the profession into two groups, one with experience and cultivated skill, to give second opinions, and the other with the wide horizon of the general practitioner. Such an arbitrary division would be condemned by public opinion, resisted by patients, and ignored by some doctors; moreover, any attempt to impose on a group an obligation not to give a second opinion would be resisted. It would be possible to stand by either of these policies (*a*) or (*b*), but not to combine them.

Many amendments were tabled. Dr. W. E. HEATH, for Rochester, Chatham, and Gillingham, desired (in vain) the remodelling of rule 2, or the reference back of the whole batch. Dr. H. GUY DAIN (Birmingham) claimed that the profession was already divided into two compartments and that a specialist must forgo certain privileges and opportunities that the general practitioner could enjoy. This amendment recognised the two groups as separate, and while forbidding those engaged in consultant or specialist practice to give advice or treatment to a patient at the latter's request, would allow the general practitioner to do so if he believes that the patient is not under the care of another practitioner. Sir ROBERT BOLAM pointed out the existence of an intermediate class for which Dr. Dain's resolution proposed no course of conduct—e.g., general practitioners doing valuable work as consultants in districts where no recognised consultants exist. Dr. HAWTHORNE said that though it might be in the interests of practitioners to confine themselves to one form of practice they could not be forced to do so. Birmingham's amendment was lost; one by Dr. A. K. GIBSON for Kensington to substitute (for the sake of uniformity) "has reason to believe" for "believe" in rule 1 was accepted by Dr. Hawthorne, as was also Dr. E. R. C. WALKER's proposal to clear up ambiguity in rule 1 by the substitution of the words "to accede to the request" for "to do so." Dr. PETER MACDONALD's amendment (for York) to refer rule 3 back to the council or, better, to the consultant group of the Association, was moved on the grounds of the difficulty which might confront the consultant whose patient refused to allow him to communicate with his doctor. "Under medical care" was an ambiguous phrase. For example, a patient under treatment by an ophthalmologist for tobacco amblyopia might be under his family doctor for a sprained ankle. The supreme instance where this rule would break down would be the case of venereal disease. The amendment was lost.

Buxton (Dr. L. S. POTTER) wished to legislate separately for treatment of a nature which could not reasonably be carried out under the direction of the usual medical attendant (e.g., spa treatment). Lewisham (sponsored by Dr. S. D. BHABHA in the absence of Dr. L. W. Bain) and North Northumberland (Dr. R. A. WELSH) were prepared to demand unconditional refusal on the part of the doctor even to examine a patient who will not allow communication with his own attendant, Dr. Welsh maintaining that it is better to lose a patient than a friendly neighbour; at any rate, the patient should be off with the old love before being on with the new. Manchester, with Dr. D'EWART as spokesman, supported by Holland (Dr. A. S. WILSON), would have "urge" strengthened to "insist" in line 6 of rule 3, and the last sentence of the rule deleted. Dr. F. A. ROPER, for Exeter, pointed out the fundamental difference that may exist between the lay view as to a patient's rights and that of an association of doctors—exemplified by the out-patient controversy. The Association held that no out-patient should be treated without a letter from his doctor, but King Edward's Hospital Fund thought otherwise. Dr. HAWTHORNE, for the ethical committee, felt that "insist" was a dangerous term to use to a patient, who might in his turn insist on the doctor ringing the bell in order that he might be shown out of the house. Sir HENRY BRACKENBURY took exception to an amendment moved by Dr. D. D. STENHOUSE STEWART, for East Yorkshire, to insert after the words "medical case" in rule 3, "in respect of the condition upon which his opinion is sought"; he quoted the truism that doctors do not treat diseases but a patient, and the meeting agreed; nor did Dr. DAIN, speaking for Birmingham Central, convince the Representative Body that to delete the words "in whatever form of practice" in the first line of rule 4, and to add the word "general" before practitioner in the same line would be a desirable alteration.

The rules were then accepted in their original form except for the minor corrections in rule 1 noted above. At this point the proceedings were interrupted for the announcement that Mr. H. S. Souttar had been elected chairman and Dr. Dain deputy-chairman of the Representative Body, 1934–1935.

Ethical Rules for Medical Inspectors

Considerable argument centred round the question whether a medical inspector (other than a school medical inspector) should himself be charged with the duty of informing the attending practitioner of the date, time, and purpose of his visit to a patient, or whether he could delegate this responsibility; the problem was solved by the inspiration of Dr. J. W. BONE to use the words "himself or through an agent" in the relevant clause.

Schools of Chiropody and Foot Hospitals

Dr. R. L. LANGDON-DOWN, acting for the chairman of the ethical committee, who in this instance dissented from the majority of his colleagues, proposed—

> That the medical profession should accord a measure of recognition to approved chiropodists who accept the following definition of their work:—
>
> > Chiropody means the treatment of abnormal nails, and all superficial excrescences occurring on the feet, such as corns, warts, callosities, bunions,
>
> and undertake:
>
> (a) to confine their practice to the field set out above;
>
> (b) not, even within the above field, to operate for (1) any congenital or acquired deformity; (2) any condition requiring either a general anæsthetic or a local anæsthetic given by injection; (3) any condition involving any structure below the level of the true skin;
>
> (c) not to treat any patient who is at the time under the care of a medical practitioner without his knowledge and consent.

Dr. Langdon-Down described chiropodists as an ancient confraternity, giving a service accepted (if silently) and even utilised by the medical profession and appreciated by the public. The field in which these specialists worked was restricted and was not cultivated by medical practitioners. The service was rendered without detriment to the public and without giving rise to any serious complaint. Of recent years the public had tended more and more to resort to chiropodists, whose methods of work and arrangements for receiving clients had developed correspondingly, and institutions such as foot clinics and foot hospitals were being widely established. Associated with this activity was the extension of courses of training. For many years members of the medical profession had assisted in this training by giving lectures and conducting examinations, and now the chiropodists aspired to a register for their members, with standards of instruction and conduct for those inscribed thereon. The ethical committee had invited doctors intimately acquainted with the aims and work of chiropodists to send relevant documents and to discuss their status. The committee had been impressed with the evidence of the good faith of the applicants for recognition, with the value of their work, and with the need for its medical recognition. The time had come when doctors must either recognise or oppose organised chiropody. One of the minor issues was the acceptance or rejection in the *British Medical Journal* of advertisements for practitioners to help them in their organisation. There were many groups of chiropodists, but the *Incorporated Society of Chiropodists* was *apparently* the most important and was the one which had sought the coöperation of the Association. The two main issues were (1) what is to be the sphere of chiropody; what limitations should be placed on the activities, practice, and behaviour of its practitioners; (2) in what relation were these to stand to the medical profession if the latter should grant them some sort of recognition. The applicants had been surprisingly ready to accept suggestions for limitation of their sphere implicit in the proposed definition. The difference between this specialty and others which had been granted recognition was that practitioners of these others undertook not to treat any patient except under the direction and control of a registered medical practitioner. Serious practitioners of chiropody could hardly be asked to submit to this condition, because the public would assuredly not accept the position and would be driven into the hands of unrecognised chiropodists who were under no such obligation. The clause was appropriate to such specialties as massage or electrical treatment, because the doctor was in a position to direct and supervise them, but the patient long accustomed to employ a chiropodist could hardly be asked to enlist the supervision of his doctor every time he went to have his corns cut. Insistence on a rule that must become a dead letter would be highly inadvisable. Chiropody was a limited and fairly easily defined sphere of work, and men properly trained in the art would be all the more competent to distinguish cases which should be referred to a doctor. Long continued treatment like that needed for corns was in a different category from occasional treatment such as massage. It remained to be considered, if recognition was granted, what form it should take. Coöperation would doubtless be sought in respect of courses of training and assistance in lecturing; doctors would be asked to send patients to chiropodists for treatment when this seemed desirable; the columns of the *British Medical Journal* would be open to advertisements ; and transgressors among approved chiropodists against the code of conduct laid down would be reported. Here was an opportunity, concluded Dr. Langdon-Down, which should be seized. If the medical profession stood aloof it would lose the power of directing and limiting the development of the specialty, or would force the public into the hands of those who might have an entirely inadequate training.

An amendment was moved by Dr. Hawthorne, for Marylebone, and seconded by Sir Robert Bolam, for Newcastle-on-Tune.

That the work of chiropodists in dealing with corns and callosities being already known and utilised, the Representative Body does not approve of giving an official collective recognition to approved chiropodists in a more extended field.

Dr. Hawthorne said that chiropody was either (1) an æsthetic enterprise, or (2) a therapeutic measure. If it was the former, the medical profession had no more concern with it than with manicure or hairdressing: if the latter, diagnosis must precede treatment, and the minimum training for diagnosis was the medical curriculum. It was to the public interest to distinguish between those who offered treatment after having been trained under this curriculum and those who had not, and the medical profession must not help to confuse the issues between these two groups. The maintenance of these principles need not imply the expression of animosity, nor that the medical profession was anxious to put down unqualified practice; it did not imply restriction *on any one member of the public from giving advice* to another, even for a fee, or the prevention of any person from taking such advice. It implied only that responsibility for taking such advice rested on the patient himself. One at least of the foot hospitals had in a shop window cushions for heel and arches for feet and a diagram showing that 25 per cent. of the ills that affect mankind are respiratory; but a footnote added that a predisposing cause was the flattening of the arch of the foot or a similar misfortune. If the arch of the foot had to sustain such a pathological burden, said Dr. Hawthorne, no wonder it collapsed under the strain. Sir Robert Bolam, in seconding, said that to legislate for a subsidiary profession and help map out their course of training would be a heavy burden of responsibility which it was not the medical profession's business to shoulder. The proposal was to legalise invasion of the ranks of certain specialist surgeons and also of general practitioners. Not all general practitioners refused to treat corns. It was, moreover, dangerous to allow persons who had not had a medical training to treat warts wherever these should occur. In regard to nails—surely abnormalities were mainly due to nutritional causes or to infection. Neither of these should be treated by a chiropodist. There was no desire to interfere with chiropodists, but also no desire to accord to any persons recognition for work in a medical field.

Dr. Eliz. Casson (Bristol) said there was no doubt that the care of corns was generally inefficient. The chiropodist started off with a knife in his hand, which was a surgeon's prerogative. From her large experience of looking after the feet of patients at a mental hospital she had come to the conclusion that most patients needed not so much the cutting of their corns but treatment of a fungus infection. Dr. J. H. Thompson dwelt on the difficulty of controlling such a service, and then Sir Henry Brackenbury set out the present position.

They were not, he said, concerned with definition of the field to which the chiropodists could properly be allocated, but with whether recognition in *any* field should be granted. He asked the meeting to dilute strict logic with a little common sense. There was a practical situation to be dealt with. The chiropodists were rapidly and increasingly extending their activities beyond the field in which they should properly work and the council had been approached, with a view of regulating the position, by orthopædic surgeons and dermatologists. At least one hospital in London, and several in the country, had a chiropodist's department, employing chiropodists. There was a *foot* clinic and school of chiropody in Edinburgh, with which nine eminent members of the medical profession were associated, and on terms of mutual cordiality. The council of the Royal College of Surgeons of England held that some form of recognition should be given, and the meeting must bear in mind the possibility that recognition might be awarded by other bodies in the medical profession. The purpose of the council was to establish the propriety of a doctor sending a patient with a corn to a chiropodist if he so desired. Dr. Hawthorne's emphasis was on the need for diagnosis, but surely a layman knew when he had a corn. There was now an opportunity to keep chiropody in a certain field, binding the main body of that profession to accept defined limitations. Mr. F. C. Pybus, for the amendment, remarked that, generally speaking, pathological foot conditions were the result of deformities which were the concern of the doctor, and that a person without medical training might fail to distinguish melanotic sarcoma from a simple wart. Dr. Noel Waterfield was for accepting and controlling the situation. Dr. J. S. Manson agreed with Dr. Hawthorne, that the evidence of the spread of chiropody should make us suspicious and critical. Practitioners of the art were now being installed in drapers' shops as a lure. At one school a syllabus of over 700 lectures on anatomy, physiology, bacteriology and so forth was included in a course extending over four months, for which 30 guineas was paid, and in others the course lasted two years and cost 70 guineas. Dr. De. Lisle Gray said that the very fact that these schools were going ahead meant that unless action was taken their position would be consolidated. He was impressed by the willingness of chiropodists to enlist the support of doctors, and to follow our ethical ruling. There was no reason why the responsibility for guidance should be shirked. Dentists had been helped in this way and patients now went straight to dentists as a matter of course. In view of the fact that chiropody had been recognised by orthopædic surgeons the motion ought to be supported. Dr. Helen Lukis also spoke against the amendment. Most doctors, she said, had no desire to acquire a reputation as corn cutters, or to give ten minutes of an evening surgery to soaking corns. Dr. E. R. C. Walker remarked that conservatism was not always synonymous with wisdom. In an atmosphere of friendly coöperation the chiropodist was much less likely to exceed his duty.

Dr. M. J. Fenton supposed that the Incorporated Society of Chiropodists wanted recognition in order to deal with small, unofficial organisations which gave an unsatisfactory training; but Dr. L. Cohen wondered what guarantee there was against a split in the ranks of chiropodists, of which one group, not accepting the agreed limitations of practice, might advertise themselves as "recognised by the B.M.A.," and get patients; while the others could say "*not* recognised by the B.M.A." and get still more patients. If the proposal for recognition was accepted the patient would tend to go to the chiropodist for all foot complaints. He suggested that this was the thin end of yet another wedge to whittle down the practice of doctors—a metaphor none the less effective for being mixed. Having started with the feet, might we not soon reach the head and have to deal with sight-testing opticians? Mr. Souttar opposed the amendment. This was a larger question than that of corns. It was desirable to recognise ancillary services as they sprung up—for example, midwifery, massage and radiography. Should the chiropodists be allowed to develop independently of doctors, or were they to be controlled? Many of them were highly trained specialists, organised by medical men, and taught by orthopædic surgeons. Should not support be given to a body of men who want to be helped to do better work? Dr. Langdon-Down said that surely it was not statesmanlike to shut down the whole question rather than to discuss freely the mode of recognition and conditions which might bring the specialty under proper control. Dr. Hawthorne, in his final appeal for the amendment, said that chiropodists were apparently not to be asked never to treat a patient, as were members of recognised auxiliary services, except "under the direction and control of" a medical man. This was the crucial point.

The amendment was carried by 102—65.

Agency for Introduction of Patients

Dr. Hawthorne differed from the ethical committee on another important question, and yet again an amendment sponsored by him was accepted contrary to the advice of the council. He proposed as an amendment:—

> That the Annual Representative Meeting regrets that the practice of the British Medical Bureau in relation to advertisements in the lay press and to the payment by practitioners to the Bureau of a proportion of fees received from patients remains without modification.

He explained that the British Medical Bureau was an agency for the sale of practices. The association took a share in its management and a substantial dividend from its profits. Among its activities was the maintenance of a list of practitioners who were prepared to take resident patients, and paid a guinea for the first year and 5s. for each subsequent year for a box number. Whatever fee the practitioner received from a patient was subject to a deduction by the Bureau. The first complaint was that this fee was payable as long as the patient remained in his house—that is, it amounted to a commission, and the second was that the list was advertised in the lay press with the object of attracting patients to one of the group of practitioners on the list. Supposing, said Dr. Hawthorne, a number of doctors, practising, say, deep X ray therapy, formed a bureau and employed an advertising agency, would that be considered ethical? Again, the fact that fees were subject to deduction was not specifically explained to clients and thus became a sort of secret commission. Dr. Casson said that a large number of practitioners took resident patients, and some were penalised because the British Medical Bureau recommended only those who were prepared to pay them a 10 per cent. commission. It was understood that the association had taken over the Bureau, which was formerly called the Scholastic, Clerical and Medical Association, Ltd., in order to have an agency adopting its code of medical ethics, but the result seemed to have been otherwise. Prof. J. W. Bigger was jealous for the honour of the association. The practice described was essentially a form of dichotomy, a secret commission divided not into two but into thousands of parts. He would doubtless be told that the Bureau was a profitable investment, but ethical considerations came first. Dr. J. W. Bone put up a stout resistance to these attacks, drawing attention to the professional and personal eminence of the directors of the Bureau, which had been conducted on much the same lines for over 40 years. He gave a brief history of what he described as a vendetta by a small group of representatives against its activities. When, in 1926, the Association had bought shares in the Bureau it gave an undertaking not to interfere with the work of the agency as a business concern or with its policy unless this conflicted with that of the Association. The attacks had been carefully considered by the directors, who reported to the ethical committee that (1) the register complained of had been published for more than 41 years, and had been advertised in lay as well as in medical papers; (2) practically all the applications came from advertisements in the lay press; (3) they did not regard the advertisements as unethical but as necessary for the business of the agency; and (4) it seemed clear the cost must be met by beneficiaries, and a continuous commission seemed to be the best method yet devised of arranging this. On this report the council had resolved by 44 votes to 3 that the practice of the Bureau did not conflict with ethical principles. Dr. E. H. Snell drew attention to the wide implications of this apparently simple amendment; if the procedure condemned were wrong so would be the acceptance of advertisements in the *British Medical Journal* for institutions for sick people, and of some at least of the money received by the vendor when selling a practice. Dr. DE LISLE GRAY said that surely it was insulting the intelligence of those who used the agency to assume they did not realise that a commission was paid. Sir ROBERT BOLAM pointed out that these advertisements had appeared in the same lay papers—the *Times*, the *Morning Post*, and the *Law Times*—for many years before the Association had any interest in the Bureau. He challenged the suggestion that such a commission as was paid was unethical; it was always understood that agencies charged a commission, either as a lump sum or piecemeal, and there was nothing wrong in this. If the meeting was not satisfied it must say so, when the directors of the Bureau would have to consider the question of resignation.

Somewhat surprisingly to most of those who observed the battle it did say so, passing the amendment by 94 votes to 76.

(*To be concluded*)

AMERICAN MEDICAL ASSOCIATION

EIGHTY-FIFTH ANNUAL MEETING

THIS year's meeting in Cleveland was characterised by large attendance (6293), excellent scientific and technical exhibits, and a growing recognition in its business sessions of the coming crisis in medical economics. The presidential address was largely concerned with the over-supply of doctors—not at all with the crying need of large sections of the population for more adequate medical care. In an age and a nation where it is reasonable to plough under cotton and wheat crops, it may not be surprising to hear the same type of remedy suggested for the excess of physicians, viz., a limitation of production.

The probability that health insurance, among other kinds of social insurance, may be discussed in the next session of Congress was foreseen. The time-honoured opposition of the Association to "any system whereby the State would in any way enter into the practice of medicine" was re-affirmed, but in so far as health insurance goes somewhat more temperately than in the past and not without evidence of a division of opinion among the rank and file. Indeed, the Michigan State Medical Society introduced a resolution in which it was stated that its commission sent to investigate health insurance in England had furnished a report which "raises certain grave questions concerning the policy of the officials of the American Medical Association toward health insurance and the effects of this policy on the practising membership . . ." This resolution was considered in executive session of the house of delegates, which means that all non-members of the house of delegates were excluded. A motion to have the resolution considered by the house as a committee of the whole was lost and a motion carried referring the matter to a special committee. This special committee succeeded in bringing in a report acceptable to the house. This report exonerates the officials of the Association, reviews the history of the opposition of the Association to compulsory health insurance, and concludes with ten principles laid down by the board of trustees as the essential bases for experiment in sickness insurance in the United States. As there is nothing in these ten principles inconsistent with a scheme for compulsory health insurance, their inclusion in the committee's resolution may perhaps be intended to offset to some extent their recital of opposition to insurance. Dr. J. D. Brook of Michigan suggested that a standing committee of seven members of the house of delegates be appointed to continue a study of this question, but his resolution was tabled.

The committee on medical economics gave some hint of the future policy of the Association in a report which states: "All said and done, sickness insurance was the product of the brain of the German chancellor, Bismarck, just half a century ago. Why? Not that adequate medical care should be provided for all, but because industry required the standardisation of expense to make more certain the exact cost of production, the better to meet keen world competition." This should be read in relation to a resolution from Indiana delegates, which points out that in European experience labour unions have never led a demand for sickness insurance, and requests the board of trustees to appoint a committee to contact, at the proper time, the leaders of organised labour.

A resolution roundly condemning the Nazi régime for expelling medical scientists "without justice or reason other than that they differed in racial origin or religion from that of their colleagues" was presented from New York. The committee on legislation and public relations, however, did not endorse this resolution, considering that the matter was covered by the more general terms of a resolution passed last year condemning the persecution of any individual on account of race or religion by any State, or under any flag. A California resolution complained that one of the departments of the Association had been recommending the pasteurisation of certified raw milk. This matter was referred to the committee on foods. The radio stations were thanked for their coöperation in matters of public education, but at the same time the board of trustees was asked to attempt some method of controlling the evil of the broadcasting of "unestablished remedies." A strongly worded resolution in condemnation of this practice was also addressed to the Federal Radio Commission.

For president-elect of the Association two names were placed in nomination: Dr. James S. McLester of Birmingham, Alabama, and Dr. Hugh S. Cumming, surgeon-general of the U.S. Public Health Service. The former was elected by 85 votes to 71. Dr. McLester is a native of Alabama, a graduate in arts of the University of Alabama and in medicine of the University of Virginia. He has studied medicine abroad at Göttingen, Freiburg, Berlin and Munich, and has had a distinguished career as teacher and practitioner in his native State. The meeting next year is to be held in Atlantic City.

LEASOWE OPEN-AIR HOSPITAL FOR CHILDREN.—This Liverpool hospital, near Leasowe, in Cheshire, with the beginning of the present year, has introduced a method of closer coöperation of the honorary medical staff and the resident medical officer. Under the new system all cases are admitted direct into beds allotted to honorary medical and surgical officers who will be responsible for their treatment. The report of the resident medical officer states that of the 572 patients treated 219 were cases of tuberculous bone and joint disease; of the non-tuberculous cases 199 were orthopædic. The average stay of the discharged surgical tuberculosis patients was 671 days; of the 67 discharged 88 per cent. were discharged with the disease quiescent; 4 cases were discharged unimproved. All tuberculous adenitis and tuberculous peritonitis cases were discharged in excellent condition with the disease quiescent after an average stay of 104 days.

THE LANCET

LONDON: SATURDAY, JULY 28, 1934

TYPHOID VACCINE: POTENCY AND VIRULENCE

RECENT years have witnessed an exuberant growth in our knowledge of the antigenic structure of bacterial cells. The resulting literature offers a formidable meal even to the professed immunologist, who must perforce attempt its digestion. But those whose interest lies on the practical rather than on the theoretical side, noting that exuberance has in this case justified its literal significance of fruitfulness, will desire to master those elements of the newer knowledge that have an immediate bearing on the practical problems of immunisation. In our present issue Dr. FELIX and Miss PITT record their latest observations on the factors involved in the virulence of the typhoid bacillus as tested in mice. In earlier studies they showed that strains of high virulence have, in the living state, the curious property of being relatively inagglutinable by sera that contain a high titre of antibodies acting on the "O" somatic antigen, which is one of the most characteristic components of "smooth" strains. In their present paper they show that this inagglutinability is associated with the possession of an additional antigenic constituent, that can be clearly differentiated from the ordinary "O" antigen by selective absorption of the corresponding antibodies. Mice immunised with a vaccine containing this additional antigen in an active form are rendered resistant to the injection of highly virulent bacilli. Mice immunised with a vaccine from which this antigen is absent remain susceptible to virulent strains. Antisera prepared by immunising rabbits with living virulent bacilli protect mice against infection with these strains; antisera prepared by immunising rabbits with killed virulent bacilli, or with avirulent smooth bacilli, have no such protective action. It would seem that heat-killed virulent bacilli have suffered an impairment of the antigenic potency of the particular component associated with high virulence sufficient to inhibit its capacity for inducing efficient antibody-formation in the rabbit, but insufficient to prevent the induction of active immunity in the mouse. If a relatively avirulent strain is used for testing—in which case the lethal dose of living organisms does not fall far below the lethal dose of killed bacteria, so that death must be regarded as resulting from toxæmia rather than from bacterial invasion of the tissues—it is found that the ordinary antisera, containing the "O" antibody, are at least as protective as the sera obtained by immunisation with living virulent bacilli. The new antigen and its corresponding antibody would thus seem to be concerned particularly with the reactions that inhibit tissue invasion.

Dr. FELIX has clearly added another observation of great practical importance to those that already stand to his credit in this field. Whether the sharp distinction that he draws between this new antigen, as determining virulence, and the ordinary smooth somatic antigen, as being mainly concerned in toxicity, is fully justified, and whether the facts that he has demonstrated in the case of the typhoid bacillus have analogies in other bacterial species, only the future can show. The essential significance of his findings lies in the demonstration that it is not enough to prepare our vaccines from smooth strains, as we had already learned to do, but that one smooth strain differs from another in its antigenic structure, and that we must select smooth strains possessing the right kind of antigen if we wish to protect against attack by strains of high virulence.

These observations of FELIX and PITT offer an explanation of the interesting results recorded by PERRY, FINDLAY, and BENSTED in a series of reports from the pathological department of the Royal Army Medical College. These workers had already been led, on the basis of a considerable series of experiments, to the conclusion that virulence for mice, rather than mere smoothness in the usually accepted sense, offers the best criterion of immunising power. In their latest paper[1] they offer additional and more detailed evidence in support of this view, showing that none of the commonly accepted tests for smoothness—colonial appearance, stability in saline, a negative Millon reaction, or the agglutinability of killed cultures by an "O" antiserum—can be relied upon as a proof of immunising value. They note, in agreement with the findings of FELIX and PITT, that their virulent and highly immunising strains are, in the living state, relatively inagglutinable with an ordinary "O" antiserum, though one at least of their agglutinable strains has shown a quite definite immunising capacity. Those who have a liking for tradition will learn with pleasure that the famous "Rawlings" strain of typhoid bacillus, which has played so honourable a part in the history of antityphoid inoculation, has, after a temporary lapse into senility and ineffectiveness, been successfully rejuvenated, and is now the most potent of the tested strains.

RE-EXAMINATION OF MENTAL DEFECTIVES

SOME characteristically outspoken remarks by the Recorder of London have drawn attention to the long intervals which the law interposes between the official occasions for reconsidering the detention of mental defectives in institutions. Sir ERNEST WILD's comments were uttered in the course of criminal proceedings against GEORGE HENRY NEWTON, charged with an offence against a young woman who is under treatment at the Manor Certified Institution at Epsom. NEWTON was stated to be a married man, aged 31, living apart from his wife. The patient had been received at Epsom in January, 1931, under the usual order which is valid for 12 months and is subject to continuance under certain statutory conditions. She had been allowed out for the day on leave of absence from time to time; NEWTON, it was said, took her to his room for a week. He pleaded guilty to the charge. The young woman's alertness and intelligence in giving evidence obviously impressed the Recorder. She said she was 24 and had been at Epsom for 4 years. "Are you happy there?" asked the Recorder. "Well, not too bad," she answered. "Do you want to stay there?" "Well, I should like to get out as soon as I can." The Recorder observed that it was wicked that "these wretched creatures" could be detained for five years without any recent certification. "I think it is an interference with the liberty of the subject that there should not be an examination for five years." He desired a special examination to be made by one or two independent doctors to see if the young woman was a proper person to be detained any longer. The legal effect of the proposed examination is doubtful, but some of the learned Recorder's observations had suggested that he was unaware that the authorities in the case before him had followed the exact procedure prescribed by Parliament in the interests of the patients. In any event, the Old Bailey is hardly equipped to act as a court of appeal from the Board of Control. The judicial duty before Sir ERNEST WILD was the sentencing of NEWTON for a criminal offence upon a mental defective; he awarded a sentence of 12 months' imprisonment in the second division, telling him that he deserved no mercy. Had the issue been the duration of the patient's detention, it would have been material to know the full facts and medical opinions relative thereto. Judges and magistrates, of course, are sometimes moved to travel outside the judicial province and to denounce the law which it is their business to administer. There are famous instances where the ironic comments of the bench have led to the reform of obsolete or inconvenient legislation.

---

[1] Jour. Roy. Army Med. Corps, 1934, lxiii., 1.

Under sub-s. (1) of Section 11 of the Mental Deficiency Act of 1913 an order sending a defective to an institution will expire a year later unless continued in the manner prescribed by the Act. Sub-s. (2) enacts that the order will remain in force for a year after the date when under sub-s. (1) it would have expired, and thereafter for successive periods of five years, if at that date and at the end of such period of one and five years respectively the Board of Control considers that the continuation of the order is required and makes an order for that purpose. The Board, before deciding upon continuance, is obliged by the Act to consider certain special reports. It must first consider a special report by the visitors (made within a month after having seen the patient) as to his or her mental condition and the means of care and supervision which would be available if he or she were discharged. The visitors must state whether they think the patient is "still a proper person to be detained in his own interest in an institution." Secondly, the Board must consider a special report by the medical officer of the institution as to the patient's mental and bodily condition. The latter report must be accompanied by a certificate that the defective is still a proper person to be detained. Thirdly, the Board must consider the report of any duly qualified practitioner who, at the request of the patient or his or her parent or guardian, has made a medical examination of the defective and the means of care and supervision available on discharge. It is worth while to remember the statutory insistence upon the "care and supervision" available on discharge when one recalls the hospitality which NEWTON offered. No other statutory provision for reconsidering the patient's detention exists except that, when the patient enters an institution while under 21, the visitors must reconsider the case within three months of his or her 21st birthday.

These being the requirements prescribed by Act of Parliament, it is hard to see any legal significance in the examination "by one or two independent doctors," which the Recorder has asked for. He can express a personal opinion that the law is wrong: but it would be unfortunate if his remarks gave the impression that the authorities in charge of the institution at Epsom have taken a fiendish delight in confining for five years without medical examination a patient who is perfectly sane. This would tend to foster the prejudice which sometimes inspires the award of vindictive damages against doctors in cases of lunacy certification. If the Mental Deficiency Act is a bad one, let it be repealed or amended. Meanwhile let us have fair play for the authorities who endeavour scrupulously to obey it in the interests of the patients themselves.

THE PATHOGENESIS OF ŒDEMA

OPINION about the cause of œdema in nephritis, having forsaken the kidney for the plasma proteins, has lately shown signs of going back to the kidney, and now hovers uncertainly between the two. The renal hypotheses, which were discussed in these columns not long ago by Prof. SHAW DUNN[1] and Dr. ROBERT PLATT,[2] are somewhat involved. The theory that œdema is due to lowering of the concentration of the plasma proteins is, on the other hand, comparatively simple; it arises from a belated application of the principle, established by STARLING, that the secretion of fluid into the interstitial spaces—excess of which produces clinical œdema—is governed by the hydrostatic pressure within the blood capillaries, offset by the colloidal osmotic pressure of the plasma proteins. Pending a final explanation of œdema in nephritis—and it seems likely to incriminate both factors—it may be instructive to turn aside and consider how far lowering of the plasma proteins can be held responsible for various non-nephritic kinds of œdema, and particularly those associated with malnutrition.

Prof. W. T. LONGCOPE,[3] who has collected evidence bearing on this question, describes several cases in which œdema arising in the course of conditions like amœbic dysentery and malnutrition could be correlated with lowering of the level of the plasma protein, apparently from protein starvation, and corrected by promoting the normal absorption and digestion of protein. He also reminds us that the same factor can be at work in the forms of dropsy commonly found in famine areas, in prisons, and in patients suffering from severe anæmia or tuberculous enteritis with diarrhœa. He wisely points out, however, that other ætiological factors must not be ignored. The rapidity with which the plasma proteins are regenerated from the enormous reserves of the muscles is so great, and the amount of protein on which the body can contrive to maintain nitrogen equilibrium is so small, that the degree of protein starvation must be very high before œdema is likely to occur solely from this cause. In one of Longcope's cases, indeed, the protein reserves were so much depleted that during treatment the patient retained an average of 17 g. of nitrogen (that is, over 100 g. of protein) a day. It must also be remembered that Benedict and others have starved normal subjects of everything but water for as long as four weeks without causing visible œdema. Perhaps the most important subsidiary factor to be considered is the salt intake. Since œdema fluid always consists of salt and water in the proportions found in normal saline, dropsy cannot develop when the intake of salt is curtailed. It cannot occur, therefore, in absolute starvation. In the conditions described by Longcope, on the other hand, the salt intake is either normal or excessive, and œdema becomes manifest to a degree which can be varied, within limits, in either direction, by regulating the intake of sodium chloride. Nevertheless the temporary and inconstant response of nutritional œdema to low salt diets and diuretics shows that, in the production of œdema, the salt and water intake is of much less importance than the protein starvation. Other secondary factors which must not be lost sight of are mild degrees of heart failure, anæmia, and the influence of posture. In reviewing the causes of the œdema which sometimes follows operations, C. M. Jones, F. B. Eaton, and J. C. White [4] put most emphasis on protein starvation, loss of protein in serous and purulent discharges, and excessive use of rectal, subcutaneous, or intravenous saline.

[2] Ibid., 1934, i., 1257.
[3] New England Jour. Med., 1934, ccx., 1242.

Longcope also quotes evidence to suggest that the œdema observed in "acute yellow atrophy" and cirrhosis of the liver are likewise referable to lowering of the plasma protein. In cirrhosis the ascites can be reasonably explained on mechanical grounds, but the explanation of the œdema of the legs which is commonly seen has taxed the ingenuity of the theorist for years. It has variously been ascribed to nipping of the inferior vena cava by the contracting liver; to pressure of the ascitic fluid on the cava (but the œdema sometimes precedes the ascites); and—refuge of the pathogenetically destitute—to hypothetical damage of the capillary endothelium by still more hypothetical toxins. It is comforting to find a more reasonable explanation at last; but it remains, of course, to be ascertained why the plasma proteins should suffer depletion in diseases of the liver. It would be a mistake indeed to suppose that the problems of œdema, either general or special, are anything like solved. A low plasma protein is probably not responsible for the dropsy occurring in acute nephritis, in otherwise healthy adolescent girls, or during the treatment of pernicious anæmia with liver extract, of diabetic coma with insulin, and of hypothyroidism with thyroid preparations—to mention only a few examples. None the less, the recognition of the part played by protein starvation in the production of œdema in obscure nutritional disorders is of immediate practical importance in therapeutics.

THE WEEK AT BOURNEMOUTH

Assuming that for various reasons high summer is the most convenient season for a congress which involves prolonged indoor sessions, it would be hard to find a more delectable meeting-place than Bournemouth. The number of hotels of all grades from simple to luxurious, the proximity of spacious buildings to each other and to the sea, the amenities of the town and the beauty of the surrounding country are only some of its attractions. And when to these are added, as this year, weather which makes sea- and sun-bathing possible before 9 A.M. and after 6 P.M., it is small wonder that those attending the British Medical Association's annual meeting this year are enjoying themselves.

The agenda which faced the Representative Body when it assembled on July 20th at the Town Hall may well have alarmed the 97 new members, but the old hands were confident that Dr. E. K. le Fleming, now in his third and last year of office, as chairman, would lead them and, when necessary, drive them through it with his customary skill. And they were not disappointed, because they completed the work just in time to collect robes and walk in dignified procession to the official religious service, held at St. Peter's Church at 4.30 P.M. on July 24th. The four strenuous days had not been without their alleviations. Business was interrupted from time to time by such diversions as visits from the Mayor of Bournemouth and the president-elect of the Association, and by periodical announcements of results of elections and certain other figures—for example, 507 for 6—which bore no direct relation to the questions under discussion but caused intense interest. A pleasant interlude in connexion with the report on Overseas Branches was the appearance on the platform in succession of representatives of the divisions in places as remote as Trinidad, New Zealand, Malaya, India, Australia, Zanzibar, Mesopotamia, and Hong-Kong. All offered greetings, and some made an eager appeal for advance notice of the visit of any colleague from home, so that a gathering might be arranged to meet him and thus keep in touch with British work. Even those who greatly prefer to take their travels without thought of professional activities could hardly fail to be moved by this request.

The representatives' dinner was enlivened by the wit of Dr. J. B. Miller of Bishopbriggs, who sketched the individual characteristics of officers of the meeting with rich imagery. Later in the evening the representatives joined their ladies at a cabaret supper.

The meeting bids fair to rank as an outstandingly successful one.

ANNOTATIONS

DEATH FROM ELECTRIC SHOCK

THE risk of dying from passage of electric current through the body is numerically small; the Registrar General during the last few years records only 50 to 60 violent deaths a year from electricity (lightning excepted). It is a curious thing that in spite of the widespread use of electric current for lighting in the home and as a source of power outside, the number of fatal accidents from its use is not on the increase, a tribute no doubt chiefly to the efficacy of means taken to safeguard the current, but partly, one may hope, to increasing efficiency in dealing with accidents when they occur. One result of the fewness of such injuries and their wide distribution is that only rarely does the practitioner meet with a case of unconsciousness from electric shock. But although their number may be no more than one a week, each death is a tragedy, for the victims are mostly young men in the prime of life, and it is a fact on which too much emphasis cannot be laid that in these cases more than in any other kind of accident survival depends on prompt aid. More than twenty years ago Dr. Reginald Morton, then president of the electrotherapeutic section of the Royal Society of Medicine, wrote a letter to our columns,[1] in which he stated that with the prompt application of first aid practically every victim can be revived, and of these nearly all will make a complete and permanent recovery, provided they were previously in a normal state of health. A current of 1500 volts is not necessarily fatal; Dr. Macdonald Critchley tells the story[2] of a boy who climbed a pylon and touched a wire carrying 11,000 volts with no untoward result other than some superficial burns and transient loss of memory. More recently Dr. Blake Pritchard who enunciated[3] a new theory of lightning stroke, confirmed the observation that the survivors of electrocution rarely have any permanent damage of the nervous system. Dr. Morton affirmed two fundamental facts: the first that death from electric shock is at first only an apparent death; the second that whatever the conditions or severity of the accident there is a period varying from a few minutes upwards during which artificial respiration will resuscitate the victim. So important is it, he remarked, to commence artificial respiration quickly that it is the bystander's first duty to see to this before doing anything else; he must not even leave the victim to summon medical aid, for it might be too late to render effective help by the time the doctor arrives. Of course he should send for medical assistance if there is anyone to send. Artificial respiration may revive the victim of electric shock within a minute or two; on the other hand, it may not, and there may be a long period during which artificial respiration is continued without any apparent sign of life. A recent circular (Form 1705, November, 1933) from the Factory Department, Home Office, tells us what was actually done in 50 fatal accidents reported to the department. In 15 of these artificial respiration was carried on for an hour or longer, in some instances under medical supervision; in 10 cases for half an hour, in 8 for 15 minutes, in 2 for 10 minutes, and in 1 for 5 minutes. In 6 of the 15-minute cases it seems that the doctor who was called in pronounced life extinct at the end of that time. In 4 cases it is definitely recorded that no artificial respiration was tried. In 11 of the cases, indeed where a doctor was on the scene within a few minutes of the accident, practically no attempt was made to revive the patient. The circular is quite definite in asserting that if a doctor on his arrival finds artificial respiration being practised he should not, because the heartbeat cannot be detected, presume life to be extinct but should advocate perseverance in artificial respiration. Evidence in the hands of the department makes it all too clear that the importance of immediate application of artificial respiration in cases of apparent death from electric shock, and of persistance in applying it, although generally appreciated now by electrical engineers, is not adequately realised by factory occupiers or, the circular adds, by members of the medical profession. Both the Silvester and the Schafer methods of resuscitation are applicable, the important thing being to apply one or other of them without a moment's delay. Artificial respiration should be combined with the inhalation of oxygen carbon-dioxide mixture as in the first-aid treatment of persons overcome by gas.

THE OXFORD OPHTHALMOLOGICAL CONGRESS

THE twenty-fourth annual meeting of the Oxford Ophthalmological Congress, held on July 5th–7th under the mastership of Mr. Cyril Walker, was attended by 116 members, and was distinctly overshadowed by the death on the eve of the meeting of Mr. Bernard Cridland, who had been the ideal organiser and latterly the master of many past congresses. On the first day a discussion on the functional diseases of the eye was opened by Sir Farquhar Buzzard and Mr. F. A. Williamson-Noble, the latter dwelling on the need for liaison between ophthalmology and psychiatry, a need illustrated later by Dr. William Brown from the disturbances of vision in war neurosis and the ocular symptoms in miners' nystagmus, for even in organic eye trouble the functional disturbance was often exaggerated by the mental reaction of the patient to his disability. Many members took part in the discussion which followed. In the afternoon of the same day Dr. H. W. Barber made an elaborate classification of diseases of the eyelids, their ætiology and treatment, and Mr. Tudor Thomas showed a patient on whom he had successfully performed his corneal graft operation. Later there was a garden party at Oriel College, and at the annual dinner in the evening at Keble Hall a presentation was made to Prof. Arthur Thomson in acknowledgment of his kindness in allowing the congress to hold its meetings from the start in the department of human anatomy.

Certain aspects of myopia were introduced by Dr. Thomson Henderson and Mr. Arnold Sorsby. Dr. Henderson regards myopia as a constitutional weakness, the yielding of the sclera to normal intraocular pressure being analogous to the yielding of the bones in rickets. If the constitutional weakness can be successfully combated, he said, the eyes will take care of themselves. Mr. Sorsby regards myopia not as a disease but as a normal variation in one direction, just as hypermetropia is a normal variation in the other, the refraction of the eye being the resultant not only of length of the optic axis but of other factors. Neither speaker had a good word to say for the still prevalent view that excessive convergence of the eyes causes myopia. Dr. Henderson submitted the following simple refutation of this theory: while the slightest pressure on the eyeball is enough to cause visible pulsation of the veins on the disc no such pulsation can be detected during voluntary convergence.

[1] THE LANCET, 1912, ii., 1539.

[2] Ibid., 1934, i., 68.

[3] Ibid., 1934, i., 1163.

The Doyne memorial lecture was given by Prof. Joseph Meller of Vienna on tuberculosis in relation to spontaneous post-traumatic and sympathetic ophthalmia. He rejected the current idea that sympathetic ophthalmia is due to a poison introduced from without, and gave reasons for his belief that it is really a manifestation of tuberculosis. His paper will appear in the *Transactions* of the Ophthalmological Society at an early date.

Among the shorter communications was a note by Dr. Oliver Pratt on the influence of diet in ophthalmic practice. Dr. Pratt finds a connexion between migraine and faulty fat metabolism, and between some forms of conjunctivitis and excessive carbohydrate consumption aggravated by lack of vitamins. Hence the value of glucose in the form of barley-sugar tablets in the one case and of halibut oil in the other. Mr. Bernard Chavasse described thermoplasty of the extra-ocular muscles; Mr. J. J. Evans and Mr. P. J. Evans dealt with congestive glaucoma, Mr. F. Ridley with the action of lysozyme, and Mr. L. H. Savin with a case of uveoparotid fever. Mrs. Lythgoe related the results of her research on the production of rosettes in the mammalian retina.

PITUITARY BASOPHILISM AND THE SUPRARENAL GLAND

THE underlying cause of the disturbance conveniently called "basophilism" is still very obscure. In the female the clinical picture is pretty clear-cut: a rapidly acquired adiposity confined to the face and trunk, striæ atrophicæ in the skin hypertrichosis, amenorrhœa, and vascular hypertension, are the common manifestations of the condition; also there may be glycosuria and evidence of osteoporosis. Cushing has emphasised the association of this syndrome with a basophil adenoma of the pituitary gland, but Leyton, Turnbull, and Bratton have described a similar syndrome in the male in two cases in which carcinoma of the thymus was revealed at necropsy[1] and the pituitary, on serial section, appeared normal. At the Mayo Clinic seven cases of the syndrome have been collected and in a recent paper Kepler and his co-workers[2] present the results of their investigation. In two examples the pituitary gland is implicated. A basophil adenoma was found at necropsy in one, and in the other patient (who is still alive) there is radiographic evidence of enlargement of the sella turcica and erosion of the posterior clinoid processes. In a third example a thymoma was revealed at necropsy, while in the remaining four cases disease of the suprarenal bodies seems to have been the cause of the disturbance. In two of the latter class the responsibility of the suprarenal is clinically proved, because the surgical removal of a large cortical tumour has been followed by a rapid and dramatic reversion to a normal clinical state; and the photographs show that these claims are by no means overstated. In view of this and of the fact that a marked hyperplasia of the suprarenal cortex has also been observed in association both with basophil adenomas of the pituitary and with three recorded examples of the syndrome in carcinoma of the thymus, the question arises whether the clinical disturbance may not be related essentially to an excess of cortical secretion. Conceivably also, as Kepler tentatively suggests, an over-activity of the suprarenal cortex may stimulate the basophil elements of the pituitary gland and so lead to the formation of an adenoma of these cells. The problem cannot easily be resolved in this way, however, because the suprarenal bodies have been recorded as normal in several cases in which a basophil adenoma has been associated with the full clinical manifestations of the syndrome. It is obvious that we are still a long way from understanding the factors at work.

A practical point emerges, however, from the above considerations. As we are unable at present to tell which of the endocrine glands should be incriminated in the presence of the syndrome there is a strong case for surgical exploration of the suprarenal bodies. If this should prove unrewarding a second line of attack lies in directing X ray treatment to the pituitary gland.

ECONOMICAL BUYING BY HOSPITALS

AT the end of 1931 the Public Health Congress appointed a committee to inquire into the possibilities of standardising hospital equipment.[1] The information on which it bases the report just issued was obtained from a questionnaire sent to nineteen representative voluntary hospitals, but the committee believe that had similar inquiries been made of the local authorities, at any rate the smaller of them, the answers would have shown an almost identical state of affairs. In brief, what was found was that there are in use too many varieties of the same article, differing only in non-essentials, the prices varying widely; that there is little evidence of expert buying; and that all known methods of purchase are employed from "retail" to "direct from manufacturer." It is a natural impulse, especially on the part of small hospitals, to buy locally and in relatively small quantities, and, on the whole, the smaller the hospital the higher the price it pays for certain commodities. This is especially noticeable in surgical materials—one hospital will sometimes pay more than double the figure charged to another. Bedsteads vary from £2 2*s.* 6*d.* to £4 15*s.* 6*d.*, each equally suitable; bedside lockers range from £1 5*s.* to £6. At all but one of the hospitals consulted the average price of a dressing trolley is £6 10*s.*; at the other one of the models cost £20 and another £17 18s. There is no standardisation in sheets, which vary from 3*s.* 3*d.* to 10*s.* 6*d.* each; pillow cases range between 7*s.* and 28*s.* the dozen. Stainless steel knives cost anything from 7*s.* 6*d.* to £1 15*s.* per dozen. One hospital actually has knives of a different finish on a hierarchical plan, running down from doctors, through nurses, ordinary patients, and private patients to domestic staff! A comparison between a large and a small general hospital showed astonishing variations, all in favour of the greater institution which bought by sample and contract, whereas the small one purchased by local tender or from manufacturers' lists. The London and the Surrey county councils provide some illuminating figures showing the difference between central and instructed buying and purchases by individual committees.

The moral of these and other figures is unmistakable. The small buyer is always at a disadvantage, since the retail market only is open to him, whereas centralised buying saves the retailers' and often the wholesalers' profits, since the manufacturer can sometimes sell in large bulk for a lower price than he quotes to the wholesale firm. The proof of the pudding is in the eating. The London County Council buys in bulk some surgical instruments and medical and surgical sundries at less than half of the retail price, and in every instance makes a substantial saving. These economies are due to a reduction in the number of types, which means standardisation with consequent reduction in manufacturing costs, and purchases in large quantities. Not mere cheapness is desired, but the most suitable article of standard form. The committee refuses to admit that it is necessary for a hospital to purchase locally from firms which support it. It is laid down as the duty of the buyer to purchase as cheaply and efficiently as possible, and that if he does otherwise he is failing in that duty. That this will be the view of the general public, from which the voluntary hospitals derive most of their support, there can be no doubt whatever, and the committee believes that most of the hospitals favour the idea of simplification and standardisation, "but no one appears willing to shoulder the responsibility for the preliminary steps." The subject is admittedly delicate. Many medical men fear that standardisation might "stereotype professional practice and hamper or destroy individual initiative," or that a hospital authority might cut down expenses to a point that would stifle all growth and development. The committee have seen a real danger, but believe that the width of the field should enable it to be avoided. After all, no surgeon is likely to object to his bandages, provided they are of good quality, being bought by wholesale at half the old price.

---

[1] Dr. O. Leyton recalled these cases, with illustrations, in his Schorstein lecture on "multiglandular disease" lately published in THE LANCET (1934, i., 1221).

[2] Kepler, E. J., Kennedy, R. J. L., Davis, A.C., Walters, W., and Wilder, R. M.: Proc. Staff Meet., Mayo Clinic, 1934, ix., 169.

[1] The chairman was Prof. W. W. Jameson, dean of the London School of Hygiene; Dr. T. Carnwath represented the Ministry of Health, Dr. Charles Porter the Society of Medical Officers of Health, and Mr. R. H. P. Orde the British Hospitals Association, and to them were added two technical representatives of the London County Council, a body which has already accomplished great things in the way of the simplification and standardisation.

The establishment of one central buying organisation for all hospitals is considered to be out of the question at this stage by reason of the cost that would be incurred before the value of the scheme could be proved. Much, however, could be done gradually and without delay by the grouping of hospitals with a view to simplification and profitable coöperation in purchasing. Meanwhile it is recognised that there is need for "a central bureau where views could be exchanged, standard types exhibited, and advice given to hospital officials." These are, indeed, the objects aimed at by the medical section of British Industries House, opened last week by Lord Derby, which seeks to become "a national buying centre for hospitals and the medical profession." Much may, perhaps, depend upon the development of this enterprise.

THE CONJUNCTIVAL CIRCULATION

Mr. Basil Graves's slit-lamp study[1] of the minute anatomy of the conjunctival vessels is the fruit of laborious years. In many persons, he finds, distinct vessels can easily be seen running more or less radially and conveying blood centrifugally towards the limbus where they turn deep in an arched course and join the episcleral vessels at the base of the limbus net or even the loops of the net itself. Accompanying many of these conjunctival vessels in which the direction of the blood stream is towards the limbus, are vessels so minute that they can easily be overlooked, in which the blood flows in the other direction, away from the limbus, and these two vessels form a loop somewhere between the limbus and the fornix. Similarly looped pairs of vessels arise from the fornix and proceed towards the region midway between fornix and limbus, where there is a fine anastomosis. Other shorter ones are in the limbus plexus itself. In one type a single relatively large vessel along the corneal border of the plexus conveys blood in one direction concentric with the limbus. On each side of the vessel there may be loops, but in normal conditions they are empty of blood, filling up readily under any circumstances which increase the superficial vascularity of the eye. At first sight the appearance of the vascular plexus at the limbus is that it is venous. Mr. Graves suggests that the efferent components of these conjunctival loops, where the rate of flow is slow, have become specialised to facilitate oxygenation of the blood and that they function as capillaries. Drawings made from actual cases illustrate the complicated connexions of the vessels.

The clinical bearing of these minute observations is not immediately apparent, but they are obviously related to the nutrition of the cornea. The paper will be a firm basis for future workers on this subject.

"SPINAL ANALGESIA IN FACT AND FANCY"

Nobody conversant with the facts has any doubt of the great value of spinal injections for analgesia. This value, however, is often obscured by failures with the method, and still more perhaps by explanations of the failures. The fact is that most failures are not to be attributed to the method but to the way in which it is employed. The same is largely true of fatalities that occur from spinal injections, and Dr. W. W. Babcock,[1] whose experience is almost unrivalled, puts the matter correctly as well as tersely when he writes: "After a death from spinal anæsthesia the anæsthetist may often properly write his own name in the space on the certificate reserved for 'cause of death.'" Babcock's article, though chiefly one of destructive criticism, is a useful addition to what has been written about spinal analgesia. It shows plainly the faultiness of much which is often accepted as true principle on which to employ the method, and it shows also, what cannot be too firmly or too constantly grasped, that success and safety depend on attention to details of technique. There is no need for great elaboration or for much use of adjuvant drugs. The anæsthetist who applies the lessons of physiology and anatomy with care and with common sense can hope for success as little tinged with anxiety as that which follows the practice of Dr. Babcock himself.

CO-OPERATION IN MEDICAL EDUCATION

It is a fact of public importance that the Governing Bodies of St. Bartholomew's Hospital Medical College St. Thomas's Hospital Medical School and Guy's Hospital Medical School have decided to establish a closer co-operation for the advancement of medical education. We have received the following from the Deans of these three important medical schools.

"The medical schools of London have grown rapidly during the last century and a half. They originated in a system of apprenticeship, under which the students became attached to individual members of the staffs of the various hospitals. Later this system was terminated and organised schools were established. Early in the present century these schools became constituent colleges of the University of London.

The range of medical education has now become so wide and the subjects included in the training of a doctor so complex that the problems of the teachers are becoming more and more difficult. It is to meet this difficulty that the co-operation between the three schools mentioned has come about. The first steps must necessarily be slow. An Executive Council has been formed, consisting of the Dean and four other members of the teaching staff of each school. Meetings, at which subjects of educational importance will be discussed, will be held throughout the year. The decisions reached will be referred to each school for consideration and such action as may be agreed. In order that the co-operation may be as close as possible the Dean of each school will be invited to attend the Council Meetings of the other two schools, when subjects of general interest are being reviewed.

[1] Surg., Gyn., and Obst., July, 1934, p. 94.

A further step has been taken. Certain courses of study are being organised for which it is difficult to cater in an individual school, but which can be arranged without difficulty when the students of more than one school will benefit. Further, the students of each school will be permitted, under an arranged scheme, to avail themselves of the clinical facilities of the other schools. In order to allow the scheme to develop gradually, in some instances the arrangements for an interchange of clinical teaching will be restricted for an initial period to St. Bartholomew's and St. Thomas's. When, after some preliminary experience, the organisation has become stabilised, similar facilities will be extended to students of Guy's.

It is hoped that co-operation on these lines will be of great value to the cause of medical education, and it is felt that the wider outlook thus made possible for the students must be of real benefit to them.

BRITAIN AND DANGEROUS DRUGS

THE report for the year 1933 on opium and other dangerous drugs furnished to the League of Nations on behalf of His Majesty's Government is both interesting and reassuring. By new regulations and an order in Council under the Dangerous Drugs Acts (1920–1932), codeine and dionin are now brought under control as regards their manufacture and distribution in this country, as well as their import and export. The assurance is again repeated that "drug addiction is not prevalent in Great Britain," and no raw opium, coca leaves, or Indian hemp are produced in these islands. Five firms—three in London, one in Liverpool and one in Edinburgh—are licensed for the manufacture of medicinal opium, two are licensed to produce morphine and one to manufacture cocaine and its salts. The gross amount of morphine (alkaloid) made in 1933 was 30,757 oz., and of morphine salts 44,169 oz. Illicit traffic in narcotics, which has flourished in certain parts of the Continent, in the Levant and in the Far East, is said to be almost non-existent in Great Britain. No important seizures were made during 1933, "nor are there any indications of illicit traffic on any appreciable scale or of the organisation of illicit traffic in Great Britain." A Spanish subject, on arriving at Southampton from Havre, was found to be in possession of 140 lb. of opium, obtained apparently from a well-known trafficker in narcotics in Hamburg, who had fled thither when released on bail in America. He, according to the latest reports, was awaiting trial in Hamburg in connection with traffic in narcotics and other charges. The amount of codeine manufactured in Great Britain in 1933 was 35,890 oz. and 23,366 oz. were exported direct by the manufacturers. There were, during the year, 55 prosecutions under the Dangerous Drugs Acts, and in all but four cases fines from £5 to £100 were inflicted, and in 14 cases imprisonment of from one to 12 months was ordered. The total importation of raw opium in 1933 amounted to 129,635 lb., the bulk of it being of Turkish origin; of coca leaves 112,509 lb. were imported, mainly from the Netherland East Indies. The total exports of morphine and its salts were 16,156 oz. or 44 oz. less than in 1932.

KEITH LUCAS

GREATNESS is a quality difficult to define without the use of negatives. It is not synonymous with brilliance nor with a distinguished career; simplicity is its keynote, and simplicity as a positive attribute is given to few. The little collection of tributes to the memory of Keith Lucas, recently published,[1] reveals this as his outstanding characteristic. In such widely different spheres as home, school, scientific exploration, physiological research, aeronautical investigation, and military life we see it emerge unfailingly. Difficulties, mechanical, biological, and human, seem to dissolve at his touch, and the courage of his convictions is ever present. Although physiology cannot claim all the fruits of his labours, its debt to him is profound—not only for his characteristically fundamental contributions to its knowledge, but for his spirit and influence. If any proof of this were necessary, the very publication of this volume at the present time would be sufficient. The cynically minded might say that 18 years after his death is a most unpropitious moment for producing biographical notes of any man, but in this case they would be wrong The papers have been written by several persons, each of whom knew him for some period of his life, and their story is told with a simple unemotional directness whose object is not to make a hero, but to pass on to those whom the war deprived of Lucas's acquaintance something of his fearless insight and generous spirit. To the late Sir Walter Fletcher we owe the conception of this memoir, most of the material for which he himself had collected, and there can be little doubt that the completion of none of his unfinished tasks would have given him greater pleasure than this.

SULPHUR IN RHEUMATOID ARTHRITIS

SULPHUR metabolism in arthritis was the subject of two communications to the international congress on rheumatism, recently held at Aix-les-Bains (see THE LANCET, July 14th, p. 111). Prof. M. Loeper and his co-workers, who have estimated the sulphur content of synovial fluid, cartilage, and blood, reported a deficiency in the joint tissues, with an excess of total sulphur and of glutathione in the blood. Dr. A. R. Neligan described a study made with H. B. Salt at the Royal Brine Baths Clinic, Droitwich, of the essential sulphur-containing amino-acid cystine in the finger-nails in arthritis. M. X. Sullivan and W. C. Hess,[2] of Washington, have observed a decrease in arthritis in general, and the Droitwich workers, using the same methods but studying cases of rheumatoid arthritis only, found an even more marked difference. For normal persons the average was 12·12 per cent.; for rheumatoid arthritis it was 7·78 per cent., and 75 per cent. of the rheumatoid cases were below the average normal figure. They also examined cases of non-rheumatic chronic disease and found that the nail cystine was low in them too (average 8·91 per cent.). They suggest that if the physiological importance of an organ may be judged by its sulphur content, the cutaneous system ranks higher than all, and ask whether it acts merely as a reservoir or has a more active rôle. The importance of the skin in rheumatic conditions is recognised; but the decrease of nail cystine appears to be a concomitant of chronic illness in general, and not of arthritis in particular. Nevertheless, the closer study of sulphur metabolism in chronic disease may help to a better understanding of its ætiology and of why sulphur does good in some forms of rheumatism.

THE DECLINE OF THE FLEA

THE numbers of all animals are subject from time to time to wide fluctuations, due sometimes to causes that are well understood, sometimes to factors that are quite obscure. A few years ago certain German newspapers announced that the human flea was extinct; and although this claim was promptly negatived by the offer of large numbers of highly priced fleas to the curators of museums, there can be little doubt that in recent years the human flea population has fallen. Fleas are less in evidence to the ordinary observer; they are more difficult to obtain for zoological laboratories; and the managers of performing fleas, who ordinarily draw their supplies from the poorer sorts of lodging-houses, in spite of paying as much as half a crown a dozen for "good bold fleas," have been hard put to it to recruit their circuses. The reasons for this decrease are not altogether clear, but there seems to be no ground for the belief that it is the result of some epizoötic disease of the flea. Some German authors have credited the change to the altered habits of dress among women; notably the disappearance of heavy woollen clothing and stockings in which fleas were formerly wont to hide. The flea, of course, is far more readily discouraged by general domestic cleanliness than is its fellow the bug; and any improvement in this direction will be at once reflected in the flea population. Then the early stages of the flea are ill-adapted to withstand desiccation; it is well known that in many parts of the tropics and sub-tropics the disappearance of bubonic plague during the hot, dry season is brought about by the fall in the rat-flea population; and it is not inconceivable that the climate of the last two summers may have proved inimical to the human flea. Probably all these and other factors have been concerned. Certainly the flea population seems to be less than it was; and those who require the human flea in quantity can often obtain it most readily, sometimes indeed in enormous numbers, from pigsties. For, like many of his other parasites, man shares his flea with the domestic pig.

PHARMACOPŒIAS PRESENT AND TO COME

FOR the second year in succession Dr. C. H. Hampshire presided over the British Pharmaceutical Conference, which met at Leeds last week. He is the secretary of the Pharmacopœia Commission, and this may be partly the reason why so many of the contributions were closely concerned with progress in the science on which pharmacy rests. The theme of his own address was pharmacopœias—British and foreign, old and modern. Beginning with the first, issued in 1618, he showed how stage by stage changes were introduced until there emerged a work which has little or no resemblance to that produced by the Royal College of Physicians of London more than three hundred years ago. We now have a book of standards instead of a catalogue of drugs and a multitude of prescriptions. Little of Dr. Hampshire's address, however, was devoted to ancient history. Turning to our own times he recalled that since 1928 seven national pharmacopœias, besides our own, have been published, three of them (the Italian, Belgian and Spanish) before the British, and four (the Danish, Swiss, Yugoslavian and Hungarian) after it. The Spanish pharmacopœia, he said, is one of the most satisfying and instructive of the modern pharmacopœias and in close relation to medical advances; the Swiss book is of great value from the pharmaceutical point of view; the Yugoslavian official volume shows the same infusion of the modern spirit, as also does the Hungarian. The Italian pharmacopœia does not include physiological methods of assay, but like the Belgian and Spanish volumes, contains a much larger number of monographs than the British. The Danish book is distinctly a pharmaceutical pharmacopœia with a preference for formulas; organotherapeutic remedies and organic arsenical compounds are not included, the reason given for the omission being that the methods of preparation and standardisation of these drugs are rapidly developing and the requirements of the pharmacopœia are intended to apply over a number of years.

There is a pharmacopœia which many besides Dr. Hampshire would like to see—an international pharmacopœia. Such an undertaking has long been projected, but an impasse seems to have been reached. The desire is as keen as ever for the unification of the standards for drugs and of the strengths and formulas of preparations through a universal volume. Differences in national standards for widely used medicinal substances are a hindrance to the spread of medical knowledge and a bugbear to pharmacists who have to dispense prescriptions brought by travellers from various countries. An international pharmacopœia would remove those difficulties, and it is to be hoped that some day Dr. Hampshire will himself have the pleasure of presenting it to the British Pharmaceutical Conference as an accomplished fact.

THE ROYAL AUSTRALASIAN COLLEGE OF SURGEONS

THE new building of the Royal Australasian College of Surgeons will be opened in Melbourne by the President of the Royal College of Surgeons of England, Sir Holburt Waring, on Monday, March 4th, 1935, and it is anticipated that a number of distinguished surgeons from England and Canada will attend this meeting, amongst whom are included Dean Lewis, D. C. Balfour, Prof. C. F. Saint, Sir William I. de Courcy Wheeler. Sir D'Arcy Power, and Prof. Edward Archibald, of Montreal, are also expected to be present. It was originally intended to hold the annual general meeting of the College at the same time as the opening ceremony, coincidental with the British Medical Association meeting in Melbourne, but this arrangement unfortunately could not be effected.

On Wednesday of last week, at a graduation ceremonial held in the McEwan Hall, Edinburgh, the Cameron prize in practical therapeutics was presented to Sir Edward Sharpey Schafer.

Lord Woolavington has given £10,000 towards the cost of establishing pay-beds, for patients of moderate means, at the London Hospital. He is also the donor of the Woolavington wing for paying patients at the Middlesex Hospital, to which he has made many large gifts.

INDEX TO "THE LANCET," VOL. I., 1934.

THE Index and Title-page to Vol. I., 1934, which was completed with the issue of June 30th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

PROGNOSIS

A Series of Signed Articles contributed by invitation

XII.—PERFORATING INJURIES OF THE EYE *

A PERFORATING injury of the eye may be caused either by a sharp instrument penetrating the wall of the globe in some position, but without being retained, or by a smaller agent (foreign body—e.g., iron, steel, copper, glass fragment) which, passing with force through the wall, is retained in the eye or may indeed pass completely through the globe and come to lie behind it in the orbit. In considering prognosis it is better to take these two types of injury separately, although there are certainly two main factors which govern both. The first of these is the severity of the injury, for in either type this may be so severe that it is apparent to the least experienced observer that the eye is irretrievably damaged and should be either enucleated or perhaps eviscerated at once. When the injury is less severe and there is a reasonable prospect of the eye being saved, the second main factor is the occurrence of sepsis.

The severe injury necessitating immediate removal of the eye is relatively uncommon, certainly as compared with the occurrence of sepsis in the less severe cases, but these two causes together constitute the chief determining factors in the loss of a wounded eye. There do not appear to be any statistics available which show the proportion of eyes so lost, except in the cases where a foreign body has been retained in the globe. I have found that practically two out of every five eyes injured in this way require enucleation; the actual figures being 424 enucleations in 1117 cases of intra-ocular foreign body under different observers. It is more than likely that this estimate is applicable to both types of penetrating injury.

Sepsis.—When sepsis occurs early and is acute panophthalmitis develops and there is no question as to the fate of the eye—namely, enucleation—but when the sepsis is of a low grade type coming on late, a week or much longer after the injury, or even years after, from late infection of the scar, much anxiety may be felt as to whether it is safe to advise retention of such an eye. As a rule an eye which shows uveitis following the trauma goes steadily downhill with gradual loss of vision and atrophy of the globe, and the patient will be saved much suffering if enucleation is performed early. When this has been postponed for some time, say two or three months, in the hope that the eye may recover, there is often headache long after the eye has been removed. This should be borne in mind in cases under the Workmen's Compensation Act, where for months after the removal of the injured eye the patient may say he is unable to work on account of headache, the existence of which it is difficult to prove or disprove. Since, however, cases in which enucleation has been performed early are rarely followed by headache, the complaint is probably genuine and is attributable to ciliary neuritis.

Sympathetic ophthalmia.—The chief danger, however, in keeping such an infected eye lies in the possibility of the development of sympathetic ophthalmia, and this is in contradistinction to the cases of panophthalmitis where the occurrence of sympathetic trouble is very rare. The site of the wound in the eye and the age of the patient are both factors which must be taken into account, especially the former. For example, it has long been recognised that the most dangerous site for a wound is the ciliary region and its immediate neighbourhood; but, on the other hand, an eye wounded in any position must, if irido-cyclitis has set in, be regarded as suspect and may be followed by sympathetic trouble in the other eye. The force of this will be better recognised when it is remembered that sympathetic ophthalmitis may be the sequela of either a cataract extraction or a hypopyon ulcer of the cornea. The shortest recorded interval between the injury and the onset of sympathetic ophthalmia is ten days and the longest about 48 years, so that the patient with a suspect eye, though he may feel that its retention is a clever piece of conservative work, is actually exposed to the risk of trouble for the rest of his life. The age of the patient is of importance, for children and young people are more prone to develop sympathetic ophthalmia than adults.

Should sympathetic ophthalmitis set in, what is the outlook for the patient? A good idea of the answer to this question can be gathered from the general agreement that it is wiser, once sympathetic trouble has started, not to enucleate the exciting eye, since this may prove in the end to be the only one in which any sight is retained. Although there are records of cases in which useful sight has been restored by various methods of treatment, the prognosis is definitely bad; and the disaster is the more deplorable when it is realised that had enucleation of the exciting eye been performed sufficiently early—i.e., within two weeks of the accident—it would never have occurred.

To sum up the foregoing one may say that the outlook for an eye that has received a perforating injury, either with or without retention of a foreign body, but followed by uveitis, is bad for the eye itself; and it is moreover a source of danger to its fellow, especially if the wound is in the ciliary region and the patient is young.

THE OUTLOOK WHEN NO FOREIGN BODY IS PRESENT

In the absence of sepsis where no foreign body is present in the globe the future of the eye depends largely on the site of the wound, and, broadly speaking, when the injury is confined to the anterior portion of the eye and concerns only the structures which lie in front of the hyaloid membrane, the ultimate outlook for the eye, both as regards vision and retention, is better than if the vitreous has been damaged.

Taking the various structures which may be wounded separately we have:—

The cornea.—Here prognosis depends entirely on the site and size of the injury; a small perforation with little or no destruction of tissue heals rapidly, and if situated away from the centre of the cornea vision is not interfered with. If the wound is larger, the iris may adhere to the posterior lips of the wound or prolapse through it, a condition which if not dealt with will jeopardise the future of the eye. When there is much destruction of corneal tissue a staphylomatous condition of the cornea may follow, leading later to loss of the eye. Reduction of vision in corneal injuries depends upon the density of the scar and its position—i.e., if in the central part of the cornea.

The iris.—A wound of the iris, per se and without complications, is not a serious matter, vision not being materially affected, but, as just stated, there may be adherence of the iris to the corneal wound which is inevitably present or a prolapse of this structure through it, and if this is not dealt with the eye may remain irritable for a long time or late infection may occur leading to ultimate loss of the eye.

The lens.—A wound of the lens almost invariably means a traumatic cataract; occasionally the capsular opening will close over and beyond a small opacity in the immediate neighbourhood nothing further will happen, but as a rule complete opacification occurs. In a young person absorption of the lens matter takes place without complications, but in older people an increase of tension is liable to supervene, necessitating surgical assistance; but provided this is well carried out no detriment follows. The outlook for the aphakic eye itself is by no means bad, for with a suitable correcting lens good vision may result, but its owner will have lost binocular vision, and is in the position of a one-eyed man, with one important and favourable difference: he retains a potential eye to be brought into action should anything happen to the good uninjured eye; moreover, the aphakic eye is of some value in seeing objects on its own side, although even dimly.

---

* This article was received on June 27th, only two days before the author's untimely death.

In one of my cases it was thought worth while to extract a traumatic cataract in an eye injured many years previously; the patient was a stud-groom and expressed himself delighted with the result, for, he said, "I can now see my led horse," although the correcting lens was worn.

The sclera.—Wounds of this structure are so frequently associated with injury to the ciliary body or choroid, together with the retina and more or less loss of the vitreous, that all these structures may be taken together and grouped as forming the injuries of the posterior chamber of the eye.

It is here more than probable that loss or disturbance of vitreous is the chief factor in determining the future outlook for the eye; it has been estimated on good authority that *if one-fifth of the vitreous is lost no vision may be expected.* Even if little or no loss takes place there will be scarring of the vitreous, which tends to lead later to retinal detachment and corresponding destruction of vision. Further, it can be easily understood that if vitreous loss occurs the retina and choroid are wounded and tend to atrophy later, with corresponding loss of field vision.

Speaking generally, one may say that some deterioration of vision, either central or peripheral or both, is the inevitable sequela of any perforating injury of the posterior chamber of the eye, and that it is greater or less according to the severity of the injury.

THE OUTLOOK IN THE PRESENCE OF A FOREIGN BODY

When a foreign body has penetrated and remains in the eye, the *site* of the foreign body is the most important factor in the prognosis.

If it lies *in the anterior portion of the globe*—i.e., in any part anterior to the hyaloid membrane but excluding the ciliary body—extraction is a comparatively simple matter and good results follow, even though the iris may be injured. The lens may, of course, be concerned and a traumatic cataract may follow, but this, if dealt with satisfactorily, should only mean an aphakic eye. Speaking generally, the outlook for an eye in which a foreign body has come to rest in its anterior portion is distinctly good, provided appropriate surgical measures have been carried out.

It is otherwise, however, when a foreign body has penetrated deeper and lies *in the vitreous* or against or even impacted *in the posterior wall of the globe,* and it is unfortunate for the patient that this is the commonest site for the foreign body to take up.

I have found and noted in the Transactions of the Ophthalmological Society of the United Kingdom (liii., p. 438), that in 374 out of 656 cases recorded by observers in this and other countries the foreign body lay in the vitreous—i.e., 57·7 per cent., and, further, that the percentage of enucleations in vitreous cases was 45·9. This appears to suggest that when a foreign body lies in its most favourite site in the globe, nearly half the cases come to enucleation. What is the outlook for the remaining 54·1 per cent. of cases where the eye has been "saved"? In a number of them the results may seem to be very satisfactory at first, to the gratification of both patient and surgeon, but as time goes on this number diminishes, and the end-results seen years after the original injury are distinctly disappointing.

With a view to ultimate prognosis in cases of this kind—i.e., foreign bodies in the vitreous or impacted in the posterior wall of the globe—I collected last year from the literature of this and other countries in addition to those under my own observation 88 cases which had been re-examined more than five years after the original injury.

In all these cases the foreign body was iron or steel and therefore responsive in most instances to the giant magnet.

Considering the importance of the subject, at least in industrial districts, together with the wide range of literature examined, the number under review may seem small as a basis for definite conclusions. Records of late examinations are, however, scanty, and only those cases were included of which full and reliable information had been available. Of the 88 cases, many of which had been re-examined at periods considerably longer than 5 years, even up to 21 years, 19 were examples of retained foreign body impacted in the wall of the globe, whilst 69 were examples in which the foreign body had been successfully removed. The visual results were classified in three grades as follows: (1) useless eyes—i.e., eyes rendered blind or with vision not better than 3/60; (2) useful eyes—vision from 3/60 to 6/12; (3) good eyes—vision from 6/9 to 6/6 or better, with results as follows:—

Eyes.	Impacted cases (19).	Successful removals (69).
	Number and percentage.	
Useless	11 (58·5)	41 (59·4)
Useful	6 (31·5)	18 (26·0)
Good	2 (10·5)	10 (14·4)

From these figures it will be seen that the chances of an eye being blind in impacted cases where the foreign body is left in situ as compared with its removal are about equal; that there is a rather better chance of a useful eye being retained in impaction than if the foreign body is extracted; but that the chance of obtaining a good eye is nearly 3 to 2 if the foreign body is removed.

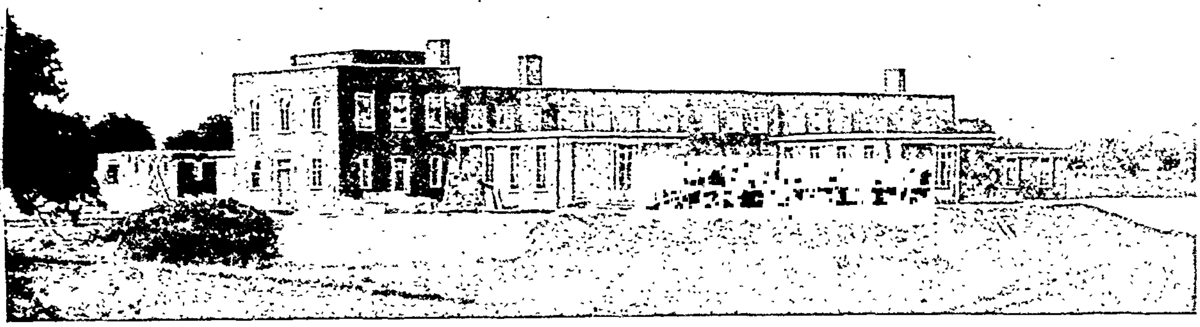
It must be remembered that *siderosis* may have to be reckoned with when the foreign body is retained and cannot be removed except at the cost of considerable damage to the eye; but siderosis, though causing grave disturbance in an eye, does not always mean its loss. An eye may show marked signs of this interesting condition and yet after removal of the foreign body may prove a useful organ and cause no further trouble. If the foreign body cannot be removed, but is small, it may become absorbed and the signs of siderosis gradually subside. The prognosis in cases where the retained foreign body is copper or brass is not good for the eye. It may be possible to extract from the anterior portion of the globe a fragment of this nature, but it is practically impossible to rescue it from the posterior chamber.

Cases are on record where copper has been retained in the globe for years, but usually owing to chemical changes taking place the condition known as *chalcosis* is set up, just as is siderosis in the case of iron fragments, and the eye comes to enucleation.

Fragments of glass or stone may be retained in the eye for many years without causing trouble, for chemical changes are not set up by their presence. The outlook, however, cannot be said to be favourable, especially when the site of retention is in the posterior chamber of the globe.

A. Bernard Cridland, F.R.C.S., D.O.,
Senior Hon. Surgeon, Wolverhampton and Midland Counties Eye Infirmary.

SPECIAL ARTICLES



THE NEW HOSPITAL AT WELWYN, JUST BEFORE COMPLETION

A LARGE COTTAGE HOSPITAL

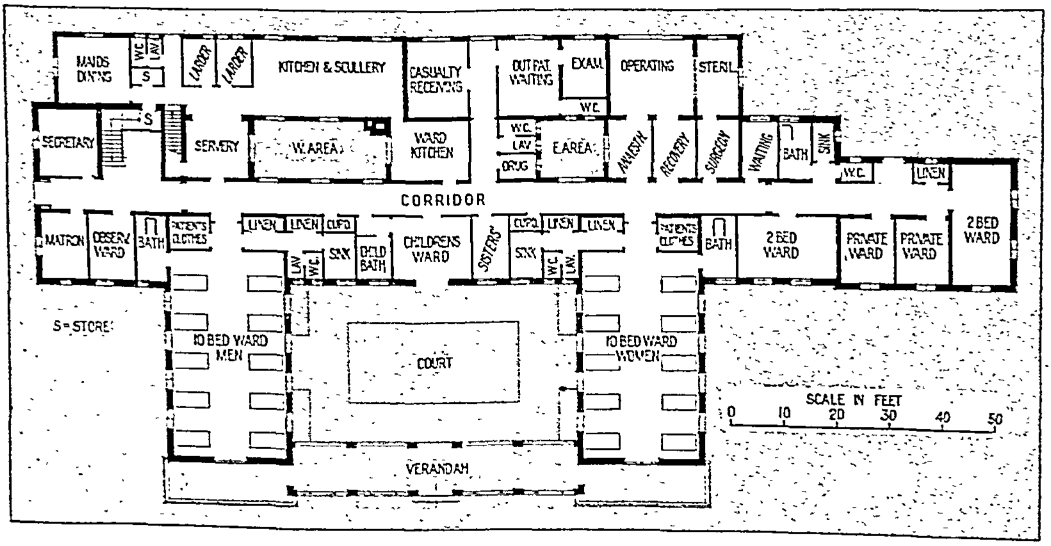
On July 24th the Duchess of York opened the new buildings of the Queen Victoria Memorial Hospital at Welwyn, Herts. The hospital was founded in 1902 with four beds and until the present time has been housed in the original building on the main Hitchin–Welwyn road, to which additions were made from time to time. The population of the district is increasing and it was being found that 12 beds were insufficient for its needs, when a bequest of £25,000 in the will of the late Sir Otto Beit enabled the committee to acquire a site of about five acres and erect a new hospital. The site is admirably adapted to its purpose, standing just outside Welwyn, high on a southern slope above a quiet lane and with wide views towards the west, east, and south. The design is by Mr. H. G. Cherry, F.R.I.B.A., working in close coöperation with Messrs. Adams, Holden and Pearson as consulting architects.

The building erected provides for 30 beds. The elevations are horizontal in character with a flat roof, and the windows, which are of metal in wood frames, have horizontal bars. It is faced in red bricks from Daneshill with dark purple quoins to window and door openings.

The main entrance, with hall and staircase to the first floor, is at the west end and is approached by a curved drive up from the road. The main corridor runs approximately east and west with a duct beneath it for pipe runs. On the northern side of the corridor are the kitchen and servants' quarters with a tradesmen's entrance in the rear the out-patients' and casualty department, and the operating suite, which is equipped with Messrs. James Slater's electric sterilisers and one gas-heated dressing steriliser. At the eastern end of the corridor a swing door leads through to the private patients' wing containing two single and two 2-bed wards. South of the corridor are two projecting 10-bed wards, one for men and one for women with a small ward for children in the centre. Large french windows at the end of each lead to the loggia for the use of patients which forms the southern boundary of the paved garden lying between the wards. The sluice-rooms and bathrooms are planned at the corridor end of the wards with direct access through a ventilated lobby.

On the first floor are a small flat for the use of the matron, the nurses' sitting-room, dining-room, and 12 nurses' bedrooms fitted with hot and cold water and so placed that they are not directly over the wards. Half-way down the corridor are a group of bathrooms and the servants' wing which is equipped with bathroom and lavatory; at the far end are quarters for night nurses, shut off by a door to ensure quiet.

The floors in the wards are of Rhodesian teak, and



PLAN OF THE GROUND FLOOR

those in the nurses' bedrooms and the sitting rooms are of jarrah. The furniture throughout the hospital is mostly of limed oak of pleasant design and colour. The tiled kitchen has a large double Esse cooker, a B.T.H. refrigerator, and a Hot-lock trolley for carrying food to wards. Wireless is laid on with headphones for each patient and also for the staff.

The ambulance garage is behind the hospital with the store rooms and a small, well-equipped laundry and drying room. In the north-western corner of the garden there is a small mortuary with a central door in front which leads into the mortuary chapel. At the side of the buildings are doors leading to the post-mortem and store room.

There is no X ray department in the hospital; an arrangement is being made with the Portable X-Rays Ltd., Chiswick, for regular service as well as emergency work.

The honorary medical staff of the hospital consists of eight local practitioners and six London specialists, also a dental surgeon and a masseuse.

INTERNATIONAL RADIOLOGY

THE fourth International Congress of Radiology, now in progress at Zurich and St. Moritz, has an interesting and comprehensive programme. The president is Prof. H. R. Schinz, and the delegates come from 30 nations. At the opening meeting on Wednesday of this week, Prof. Gösta Forssell speaks on Principles in the Fight against Cancer, and representatives of the various nations report on the organisation of the campaign in their own countries. Thereafter, every day, there are two "general reports" on special subjects, while six sections meet to discuss such different subjects as radiographic technique, the use of the cinematograph in rontgen diagnosis, radiotherapy at 700 kilovolts, and the action of ultra-short Hertzian waves.

Prof. Kienbock, of Vienna, opens the discussion on the diagnosis of tumours of bone, and Prof. Herrnheiser of Prague that on radiodiagnosis of pulmonary tuberculosis. Therapy is particularly well represented, the subjects for discussion being the radiation treatment of cancer of the uterus, and of malignant tumours of the mouth and pharynx. The openers are Dr. A. Lacassagne of Paris and Prof. F. Perussia of Milan, and among those taking part are such well-known men as Prof. Regaud, director of the Fondation Curie, and Dr. E. Berven, director of Radiumhemmet. A new subject to many members is "radiation genetics," a subject of experimental investigation by American and German observers: Mutation of genes and chromosome rearrangement can be produced by radiation, and these may result in hereditary diminution of fertility. Also stimulating in its outlook is the paper on mitogenetic radiation by Dr. S. Salkind of Leningrad, who believes that there is a definite relationship between the biological effects of this form of radiation and the production of cancer.

From a discussion of identical physical measurements of the dose in X ray and radium treatment, it is hoped that definite guidance will be given to those engaged in such therapy throughout the world. At the third congress held in Paris a special committee was appointed to investigate this problem and to report to this meeting, and all who realise its fundamental importance are awaiting the verdict of the distinguished workers led by Prof. Holthusen of Hamburg. Dr. R. Sievert of Stockholm speaks on hard gamma rays, cosmic radiation and earth radiation, and a paper in this discussion will be given by Prof. Piccard of Brussels, famous for his stratosphere ascent, who takes for his subject the method of investigating radiations at a great height. The last general paper is on short wave therapy, another comparatively new subject which has many points of interest.

Besides these special meetings the six sections meet daily, and over 400 members are reading papers. In addition there is an international exhibition of apparatus, one of books, and a demonstration of the application of radiology to the investigation of materials and paintings. The opportunity of seeing the latest apparatus of European and American firms will be very welcome.

MEDICINE AND THE LAW

Christian Science Treatment of Intestinal Obstruction

THERE is seldom anything fresh to record at inquests upon the death of persons who have undergone treatment by Christian Science practitioners. Anyone who has attained years of discretion is perfectly entitled to call in any kind of assistance when he is sick, or no assistance at all. Where the patient is too young to look after himself, Section 1 of the Children and Young Persons Act (replacing Section 12 of the Children Act of 1908) makes it possible to punish the neglect of parents or guardians who omit to obtain necessary medical or surgical treatment. Otherwise, there is no law which compels the calling in of a doctor. Where a Christian Scientist has met his death, the coroner can ascertain the fact that proper medical or surgical treatment would have averted death. The coroner may or may not advise the jury to send for trial practitioners whose treatment appears to have accelerated or assured a fatal result. If he knows that no jury at assizes would find such practitioners guilty of manslaughter there is no point in his encouraging a coroner's jury to pronounce the verdict which will commit the practitioners for trial. The coroner is concerned to ascertain the cause of death not the religious convictions of the deceased. If the dead man and his family, believing that more things are wrought by prayer than this world dreams of, have relied on that belief to the exclusion of human aid and of accumulated knowledge, then the coroner and his jury may deplore the result but can only record what they find.

At a Southport inquest last week a man was found to have died of heart failure due to chronic toxæmia, the result of chronic intestinal obstruction caused by stricture. He became ill at Whitsuntide and consulted four women Christian Science practitioners, two from Southport, one from Manchester, and one from Rochdale. One of these, questioned by the coroner, said that prayer might cure a man who fell off a ladder and smashed both his thighs; prayer, she said, could cure a stricture. Dr. W. E. Cooke, pathologist to Wigan Infirmary, definitely stated that the lack of medical skill resulted directly in the death of the deceased. He would probably have been cured up to within a week of his death if a doctor had been called in. Dr. Cooke commented on the fact that the Christian Science practitioner who had allowed the patient's condition to continue to its fatal conclusion had been trained as a qualified nurse. The coroner, Sir Samuel Brighouse, trusted that the inquiry would convey to the public the mistaken nature of the treatment. He was saddened to think that his fellow-men believed that if someone broke a leg at Ormskirk someone in Southport could pray for him and thereby cure him. The jury expressed disgust and censure at the treatment of the deceased. The coroner observed that he would have advised them to send the Christian Science practitioners for trial if he had thought there was the slightest chance of their being convicted.

IRELAND

(FROM OUR OWN CORRESPONDENT)

A CLEAN MILK BILL

THE long-expected Clean Milk Bill was introduced in the Dáil last week and has now been circulated. Without imposing any harsh restrictions on those engaged in the milk trade it appears to make provision for a fairly satisfactory control as far as the public health is concerned. The Minister is given power to prescribe by regulations the designations which may be used for milk sold or exposed for sale, and such prescribed designations shall be known as "special designations." Sale of milk under special designations will be limited to persons who have been granted licences for the purpose. Part III. of the Bill deals with the prevention of disease likely to be caused by infected milk, and the following such diseases are enumerated: tuberculosis, typhoid fever, paratyphoid fever, diphtheria, membranous croup, and scarlatina, together with such other diseases as the Minister may from time to time declare by order. Fresh powers are given to medical officers of health to aid them in investigating the source of disease which may be due to milk, and to prohibit the sale of milk from a particular dairy or of milk derived from a particular animal. The powers so conferred cover the examination not only of the dairy and the milk, but also of any person engaged in the service of the dairy, or resident in the dairy, or resident in any premises where any person employed in the dairy may reside. It is made an offence to sell milk which is infected with disease, if the dairyman knew or could by the exercise of ordinary care have ascertained that such milk was infected. It is also made an offence to sell milk to which an infected person has had access. Part IV. is concerned with the sale of milk from diseased cows. It is made an offence to sell milk from cows suffering from any of the following diseased conditions: tuberculosis of the bladder, any tuberculous condition of the uterus, any form of tuberculosis in which tubercle bacilli are excreted, any septic condition of the uterus, acute mastitis, chronic mastitis, actinomycosis of the udder, anthrax, foot-and-mouth disease, suppuration of the udder, retained placenta, and every other disease which may from time to time be declared by order. Various minor provisions in the Bill deal with the control of the conditions in which milk is produced and distributed.

HONORARY DEGREES AT THE NATIONAL UNIVERSITY OF IRELAND

Honorary degrees were conferred by the National University of Ireland last week on several members of the staff of the medical faculty of University College, Dublin, and on other distinguished graduates of the University, as follows:—

M.D.—Dr. E. P. McLoughlin, professor of anatomy and dean of the faculty of medicine, U.C.D.; Dr. J. N. Meenan, professor of systematic medicine, U.C.D.; Major W. R. O'Farrell, pathologist to the Mater Misericordiæ Hospital, Dublin; Dr. T. T. O'Farrell, professor of pathology and bacteriology, U.C.D.

M.Ch.—Mr. H. S. Meade, professor of systematic surgery, U.C.D.

M.A.O.—Dr. Robert P. Farnan, professor of midwifery and gynæcology, U.C.D.

The Chancellor of the University, Mr. Eamonn de Valera, presided, and tributes were paid to the work of each of the candidates by Dr. Denis J. Coffey, president of University College, Dublin.

PARIS

(FROM OUR OWN CORRESPONDENT)

THE VILLEJUIF CANCER INSTITUTE

THE new cancer institute which Prof. Roussy has brought into being at Villejuif in the suburbs of Paris has now been inaugurated by the President of the Republic. Roussy began this undertaking a dozen years ago on a modest and tentative scale, increasing the number of beds from 10 to 50 in the course of the first few years. Now there are some 150 beds, and the institution, which is attached to the Paris faculty of medicine, has become a model of its kind. One of Roussy's guiding principles has been the inclusion, in a single unit, of clinical services and research laboratories. On the clinical side, the 150 beds are more or less equally distributed between the three services of radium, X rays, and surgery. The medical staff on this side alone numbers about 25. On the laboratory side, there are as many as six different departments—for experimental medicine, pathological anatomy, serology and bacteriology, cytobiology (tissue culture), general chemistry, and physical chemistry. Here there is a staff of about 20.

CONTROL OF ARTIFICIAL MALARIA

The dangers of infection from patients inoculated with malaria for the treatment of general paralysis have led to the appointment of a commission which has recently presented its report to the Academy of Medicine. The gist of its recommendations is that inoculation with malaria should be permissible only in approved centres, and that these should preferably be in urban areas where skilled assistance is available. Elsewhere they should be provided with netting fine enough to keep out the anopheles. It is also recommended that psychiatrists collaborate with a biologist who will alone be responsible for the inoculation of patients and the control of the malaria thus induced. Further, no patient thus treated should be discharged or transferred to another institution until his recovery from malaria has been demonstrated by clinical, microscopic, and serological examinations. The Academy has adopted this report, whose immediate presentation to the Minister of Public Health has been urged by its authors. It may be remembered that, as early as 1929, the Academy adopted somewhat similar recommendations, and its return to the charge on the present occasion indicates the fate of its earlier proposals.

FIRST AID BY THE PARIS FIRE BRIGADE

The remarkable efficiency of the first-aid service rendered by the Paris fire brigade is largely due to the initiative and capacity of Lieut.-Colonel Cot, who, in 1926, outlined his ambitious programme in the *Archives de Médecine et de Pharmacie Militaires.* The following figures speak for themselves. In 1930 the fire brigade rendered first aid to about 100 persons. In 1931 this figure rose to 230; in 1932 to 480; and in 1933 to about 800. The rapid improvement in the proportion of cases in which first aid was successful after gas poisoning, submersion, and electrocution was still more impressive. In 1928 this proportion was 50 per cent. In 1930 it rose to 65 per cent., and in 1932 to 85 per cent. These results have been achieved by the mastery by the members of the fire brigade of the technique of first aid to the class of case they have to deal with, and by the machinery devised for bringing these experts to their field of operation as promptly as possible. There are now four mobile first-aid units attached to the fire brigade. There are also three stations where "carbogene" containers can be recharged. (Carbogene is a mixture now produced commercially consisting of 95 parts of oxygen to 5 parts of carbon dioxide.) As soon as the first-aid services of the brigade are required, someone runs to the nearest alarm box, breaks the glass, and telephones to the station of the district involved. A motor-car manned by eight men sets out promptly, its outfit including an apparatus for artificial respiration and a carbogene inhaler provided with two cylinders with a capacity of 300 litres of this mixture under a pressure of 150 kg. The first aid rendered varies, of course, with the cause of the accident (asphyxia, electrocution, &c.). The medical officer on duty promptly follows his team in another motor-car in which, in addition to the outfit already mentioned, there is a medicine chest provided with drugs, dressings, and splints. Arrived at his destination, he receives the report of the leader of his team, makes a rapid clinical examination of the patient, and sees that the treatment he receives is the best. It is the pace that saves.

MORE B C G STATISTICS

On June 5th Prof. Léon Bernard, on behalf of Dr. Guérin, presented to the Academy of Medicine statistics dealing with Mulhouse and 26 neighbouring communities in which, during 1933, 2036 infants were born. B C G was given to 1267 of them (62 per cent.). The deaths during the first year of life numbered 16 for the controls and 12 for the B C G babies, the respective death-rates being 2·15 and 0·94 per cent. In another conglomeration of 28 communities, over 80 per cent. of the 708 new-born infants—i.e., 527—were given B C G. In the first year of life there were 9 deaths among the non-vaccinated controls and 19 among the B C G babies, the death-rate for the former being 7·43 per cent. and for the latter only 3·35 per cent.

VIENNA

(FROM OUR OWN CORRESPONDENT)

JEWISH DOCTORS IN AUSTRIA

THE economic crisis, together with political unrest and the sad example set by Germany, has changed the situation of a large proportion of the medical profession in this country. Hitherto, out of about 7800 medical men and women, some 7100 have lived and worked in Vienna, with its population of 1,800,000. The peculiarity of the profession in Vienna has been that about half its members were of Jewish race or extraction, whereas in the provinces the proportion of Jewish doctors was not more than 5·8 per cent. This is explained by the fact that out of the 250,000 Jews in Austria 200,000 live in Vienna. As they have been almost debarred (not by law, but by custom) from appointments in the civil service, the municipalities, the post office and the railways—in fact, from public service—their intellectual members have had to turn to medicine, the Bar, journalism and commerce. Especially in Vienna the first two vocations have been followed chiefly by Jewish students—not to the detriment of the professions concerned. Now, since democracy has been done away with, and the racial or religious aspect has been given overwhelming importance in all affairs pertaining to economic problems—for we must clearly understand that all this political unrest is simply a matter of "give us our daily bread"—a silent, secret, but relentless battle is being waged by the circles at present ruling this country against what they call "not national people," the Jews. (Incidentally, Jews have been here in large numbers for at least 700 years.) As regards medicine, all Jews holding any appointments, even of a minor character, in the hospitals, asylums, school clinics and laboratories, are more or less gently eliminated; if their term of service expires, it is not renewed; no new appointment is given to a Jew. The same holds good in panel practice or the Krankenkassen: they are dismissed, with or without pension, as the case may be. A very serious matter is that the training of the would-be specialist, as well as of the ordinary practitioner who has not served his term, is completely at a standstill if he is a Jew. The existing regulations do not allow a doctor to settle down and practise as a recognised specialist, unless he has served at least four years in his intended branch of medicine, as "secundarius"—i.e., junior medical officer of a clinic. This is at present out of the question for Jewish doctors. Their chances of having the recognised training are simply cut off, for either they are quietly ousted from the clinics, or they are not accepted. For more than a year no Jewish doctor has obtained an appointment in the Vienna general hospitals, whilst others without any training at all—but "nationals"—have been appointed in charge of wards or as assistants. This was made manifest recently, when the famous chief of a children's hospital abruptly resigned his office. His (Jewish) assistants had been dismissed, and two others were appointed who had only passed their examinations quite recently and had no specialist knowledge at all. The professor declared himself unable to run the big children's clinic without adequate help. His protest had no effect; the responsible authorities were glad to get rid of him by these means, for he, too, was a Jew—on the verge of resignation, it is true, but still a famous man and fit for hard work. Such examples can be multiplied.

The fact is that about half the medical profession in Vienna are threatened with starvation. There will be no young specialists amongst the Jewish population. In the provinces all the Jewish doctors (they number about 200 all told) are in the same plight, and no one knows what is to be done if the present mentality of the ruling circles remains unchanged. At the same time all protests coming from the Jewish community are met with the official assertion that no antisemitism exists; it is simply that the authorities are at liberty to choose, for all sorts of work, such candidates as they think qualified best for it.

QUEEN'S INSTITUTE OF DISTRICT NURSING.—At a recent meeting of the council it was reported that 64,144 midwifery cases were attended by 1000 Queen's nurses and 2855 village nurse-midwives in England and Wales. The maternal death-rate was 2·26 per 1000, as compared with 2·1 per 1000 in 1932; the rate in outer areas was 2·3 per 1000—0·1 more than in rural districts. Statistics of the attendances of Queen's nurses on notifiable and other diseases in connexion with public health authorities showed 15,352 cases of pneumonia, 3553 of complication in relation to childbirth, and 553 of measles with pneumonia.

CORRESPONDENCE

VIRUSES IN RELATION TO THE ÆTIOLOGY OF TUMOURS

To the Editor of THE LANCET

SIR,—In writing of Dr. C. H. Andrewes's valuable contribution to this subject in the Oliver-Sharpey lectures concluded in your last issue, nothing but admiration can be expressed for his balanced and critical exposition, and particularly for the manner in which he has marshalled the salient *objections* to the virus hypothesis. On the other hand, certain observations invite obvious comment, and it is difficult for instance to grant any justification for the statement that "the size of the tumour agent is evidence in favour of its living nature."

It is natural that much significance should attach itself to the successful propagation of the Fujinami fowl myxosarcoma in adult ducks and to the transmission of the Rous sarcoma and other fowl tumours to the pheasant. While the duck may be regarded as "a species widely removed from fowls" and the pheasant as a "foreign host," it should be pointed out that transmission in these cases is nevertheless within the limits of blood relationship as judged by the quantitative precipitin reaction. In the accompanying Table data are quoted from Graham-Smith's classical researches on this subject (in Nuttall's "Blood Immunity and Blood Relationship," 1904) and it can be seen what extraordinary interest these figures possess and what light they throw on the present topic.

Quantitative Measurements with Antisera to Birds' Egg-albumin. (After Graham-Smith).

Egg-albumin tested.	Amount of precipitum.	Percentage.	
Fowl (old)	0·0159	100	Tests with anti-fowl-egg serum.
,, (fresh) ..	0·0140	88	
Silver pheasant ..	0·0075	47	
Pheasant	0·0075	47	
Duck	0·0037	23	
Duck	0·0384	100	Tests with anti-duck-egg serum.
Pheasant	0·0328	85	
Fowl	0·0234	61	
Silver pheasant ..	0·0140	36	

Furthermore, transplantability of fowl tumours to the pheasant is within the limits not only of blood-relationship but also of bastardisation. Poll's *Mischlingsstudien* included a phasianus ÷ gallus cross, and such hybrids have been used in experimental work by Taibell (Riv. biol., 1932, xiv., 55). Again, Trofimov and Tiniyakov have recently drawn attention to the close resemblance between the chromosome-complex of *Phasianus colchicus* and that of the domestic fowl (Biol. Zhur., 1933, ii., 33, English Summary).

All these facts indicate that transplantation between fowl, pheasant and duck should be regarded as within the physiological limits of relative tissue-compatibility. The successful demonstration of the transmission of a fowl tumour to pheasant or duck does not therefore make it less likely that the filtrable agent is a cell-derivative on the one hand or more likely that it is an independent parasitic virus on the other.

Dr. Andrewes has pointed out that "the neutralisation of the Rous virus with anti-fowl serum does indeed suggest most strongly that the virus is more intimately associated with fowl-protein than are other viruses with the proteins of their hosts." This and other features such as the strict specificity of the agents seem to me to indicate that the conception of the agent as an intrinsic cell-product may more than possibly prove correct. The source of the contrast in behaviour between avian and mammalian tumours may then be traced to some inherent cellular difference in the two classes, and already signs are not lacking that some such significant difference may indeed exist. White (Jour. Genetics, 1932, xxvi., 345) studied the somatic chromosomes in 40-hour embryo chicks, and drew attention to the great range in size of the individual elements in the somatic metaphase plates, the smallest ones in the centre being absolutely on the limit of resolving power of the microscope (about 0·2 μ in diameter). This range in size of the chromosomes he regarded as characteristic of birds in general and quite unparalleled elsewhere.

Obviously the data are not yet sufficiently complete to justify any permanent conclusion. We must be grateful for Dr. Andrewes's summary of the present position and await the accumulation of those facts which alone will clarify this fascinating though difficult problem.

I am, Sir, yours faithfully,

ALEXANDER HADDOW.

Department of Bacteriology, University New Buildings,
Edinburgh, July 23rd.

SCARLET FEVER EPIDEMICS

To the Editor of THE LANCET

SIR,—As many of us must, during the past year have had to cope with epidemics of scarlet fever, I have been wondering if there is any satisfactory method of controlling the spread of this disease in ordinary practice.

In 1928, with permission of the honorary staff at the Queen's Hospital for Children, Hackney, I made trial of scarlet fever antitoxin (Burroughs and Wellcome). As an example of this use: one child in a ward having been removed with typical scarlet fever, the remaining seven children were Dick-tested; three were positive and four negative. Scarlet fever antitoxin in graduated doses was given to those showing positive reactions. Three days later they were all negative. No further cases occurred. Following another case later in another ward, the same procedure was adopted, all those showing positive reactions receiving antitoxin; again there was no spread. The method is more applicable to institutions because infectious disease is there instantly discovered and prompt isolation and other precautionary measures are possible. In private practice, if immunisation is to be carried out, it seems inevitable that it must be indiscriminate, without recourse to Dick-testing. I have myself used this method in practice, but with varying results. It seems that we can only offer to contacts, usually parents and relatives, a means of prophylaxis which we must state definitely to be of doubtful value; that we may be justified in urging it for young children, debilitated persons or those with intercurrent disease; and that we can give expectation of probable prevention of the disease, or, if it is acquired, an illness less severe and with less likelihood of unpleasant sequelæ.

It would be very interesting to me, and I venture to think, other members of the profession, to know of experiences or opinions formed from the use of the scarlet fever antitoxin in the practice of general medicine.—I am, Sir, yours faithfully,

Bourne, July 21st.   W. B. R. MONTEITH.

DISPLACEMENT OF THE INTERNAL EPICONDYLE INTO THE ELBOW-JOINT

To the Editor of THE LANCET

SIR,—In your issue of July 14th is published a most interesting article on this subject by Mr. N. W. Roberts. In his first two cases Mr. Roberts proved that it is possible, if the skilled manipulation be done sufficiently early, to dislodge a detached internal epicondyle that has been caught between the humerus and the ulna, and to restore it to something near its normal position, and this without recourse to open operation. The manipulation has twice been carried out successfully by one of us (St. J. D. B.). On the first occasion, a procedure similar to that described in the article under discussion was performed. On the second occasion the inner aspect of the elbow-joint was exposed and then the manipulation was carried out, showing how the epicondyle will come out of the joint provided it is carried out within a few days of the injury. Whether the necessary manœuvre is entirely free from risk we rather doubt.

Mr. Roberts' third and fourth cases are of an entirely different type, and their inclusion seems rather to confuse the issue. The internal epicondyle in these cases was no more *in* the joint than other structures displaced by the partial dislocation. One might as well say that the tendon of the brachialis anticus was *in* the joint in every case of posterior dislocation of the ulna. Reduction of the subluxation and of the displacement of the epicondyle in these cases should not have presented any special difficulties, and the success achieved, in our view, is in no way comparable to that obtained by Mr. Roberts in his other cases. In the first two of these cases the epicondyle was caught and held between the humerus and ulna, and could only be dislodged by a very skilful manœuvre or by operation, whereas in the second two the epicondyle was only displaced by its connexion with the ulna, and was never caught between the bones, though in the last this might have resulted if the reduction had been in other hands.

There seems no doubt but that separation of the epicondyle is usually the result of violent abduction of the forearm, what we like to refer to as "attempted dislocation." As a rule the gaping joint closes again leaving the epicondyle more or less displaced. Very rarely it is sucked into the inner side of the joint and prevents the humerus and ulna from coming together again. The ulnar nerve may or may not be damaged. If outward dislocation occurs the epicondyle follows the ulna and will be pushed inwards on reduction, with little chance of being caught between the bones. Again, when posterior dislocation occurs the internal lateral ligament may be torn or the epicondyle avulsed. In the latter case the epicondyle is naturally forced into the empty sigmoid notch by atmospheric pressure. On reduction the epicondyle may not slip out of the way, and then it is caught between the bones. We have films of two cases showing this sequence of events. In 1924[1] one of us (H. A. T. F.) referred very briefly to four cases of nipping of the epicondyle between the bones. Twenty-one others have since been seen by one or other of us, making a total of 25. Unfortunately none of these were seen before the dislocation, when present, had been reduced. It was difficult, and sometimes impossible, to get any clear details of the exact condition after the accident, but there appears to have been a clear dislocation, which was then reduced, in 16, and definitely no dislocation in 3. The ulnar nerve suffered damage in 12, two being cases without dislocation. Only three cases were dealt with less than seven days after the accident, and in many the interval was very much longer. With one exception every case was treated by open operation.

In the first place may we suggest that it will simplify matters if the above title be applied only to those cases in which the detached fragment is lying actually between the humerus and ulna? Secondly, the decision has to be made whether the patient benefits by manipulative treatment in place of open operation in cases of displacement of the internal epicondyle into the elbow-joint: (*a*) when no ulnar nerve paralysis is present, and (*b*) in the presence of ulnar nerve paralysis.

(*a*) It is fair to assume that manipulative treatment is likely to be successful in displacing the fragment and probably aligning it into a position compatible with a first-class result. Experience is too small to express an opinion as to whether ulnar nerve paralysis will follow such a manipulation in any of the cases. (*b*) In the presence of ulnar nerve paralysis, the manipulation appears to be a procedure not without danger. Should the reduction be successful, the patient may be faced with an operation for transposition of the ulnar nerve. Operative experience shows that open replacement of the fragment, combined with anterior transposition of the nerve in those cases in which the surgeon thinks this wise, is an eminently satisfactory method of treatment, although recovery may be slow. It is urged, therefore, that the general principle of a nerve injury complicating a fracture indicating operation, should be adhered to in cases of ulnar paralysis complicating displacement of the internal epicondyle into the elbow-joint.

We are, Sir, yours faithfully,

H. A. T. FAIRBANK.

PERINEO-ABDOMINAL EXCISION OF THE RECTUM

To the Editor of THE LANCET

SIR,—I have read with great interest and pleasure Mr. Gabriel's article in your issue of July 14th, and my appreciation is heightened by the fact that I have enjoyed the privilege of seeing him perform this operation at St. Mark's. I am sure that he will agree with me that surgery is indebted to Prof. Grey Turner, of Newcastle, for having introduced operators to this order of events in "combined operations" for cancer of the rectum. I was first introduced to the operation by watching it in Newcastle in 1919, and the method was published in the *British Medical Journal* (1920, ii., 734) by the originator.

For those who dislike terminological hybridity, the name "perineo-abdominal" may not be the best from an etymological point of view: I plead guilty to having introduced the term myself a few years ago, and although "I have the Greek," as we say in the Far North, I have, alas! been responsible for perpetuating a heterogeneous combination, to which we were first introduced by the great proctologists who perform the operation in the reverse direction. The description "sacro-abdominal" is a better literary combination, but is hardly so accurate a description of the modern operation which Mr. Gabriel has so well described.

I am, Sir, yours faithfully,

Harley-street, W., July 18th. G. GORDON-TAYLOR.

PANEL AND CONTRACT PRACTICE

Medical Cards

THE last report of the organising medical secretary the London Panel Committee tells of various ways which the doctor's time is used up in explaining ocedure to insured persons.

THE MISLAID CARD

If for some reason an insured person cannot find is medical card he has to fill up a postcard form Med. 50), on which he gives particulars of his insurnce status. This is posted to the insurance committee hich, after verifying the particulars given, send him blank new card. He is instructed to take this card o the doctor of his choice who, if willing to accept im as an insured person, fills in Part A of the new ard agreeing. The doctor then posts the card to the ommittee which returns it to the patient. Several ostages are involved in this cumbrous procedure. lthough, in fact, an insured person can obtain form Med. 50 from a local post office, he generally obtains it rom the doctor he is consulting. If, therefore, it ontained the necessary form of words for his acceptance, the whole business of joining a doctor's list could be effected on a single form.

CHANGE OF DOCTOR.

This is not always a simple matter in view of the fact that some insured persons vary widely in educational attainments. Some can hardly read at all, others often cannot read English. The instructions are couched in language that is not easy for the unlearned to follow. Take for instance the following :

> "It is regretted that it is necessary to return the enclosed communication, but as the individual signatures of the applicants to transfer are not endorsed thereon it is not possible at the moment to grant the authority you require. As soon, however, as the attached letter is duly signed by all the persons concerned or, alternatively, separate applications are received, the necessary consent to transfer will be given."

This could surely be expressed more simply. Under present regulations it frequently happens that an insured person misses, it may be by a day or two, his right to transfer at the beginning of a quarter. If, for instance, he sends in a Notice on March 3rd, he will be at least two days late for transfer on April 1st, and will not be allowed to change doctor until July 1st. If during that period treatment becomes necessary he is, of course, still entitled to it from his present doctor ; but as he wants to change he is not likely to consult him, and he pays for treatment elsewhere. Why should he not be allowed a few days grace ?

IRREGULAR TRANSFERS

The doctor is supplied only with the name of the insured person who has transferred, not with his address. This makes it difficult for him either to spot an irregular transfer or to communicate with the insured person about it. A further difficulty arises when a patient living near the border of one county committee moves—it may be only across the street —into another committee's area. Such a patient is sent a new medical card with no doctor's name on it, from which he concludes he has been removed from his old doctor's list (as of course he has been), and that he must, therefore, choose a new doctor; whereas, provided his old doctor is on the insurance list of the new committee—and most medical men living near the borders of committee areas generally join both or more committees in that area—the patient is at liberty and likely to wish to remain under the care of his old doctor. It should not be difficult to convey this by a suitable slip to these border transfers.

The primary difficulty in all these medical card matters is to put in, or on, or with, the card information which will catch the eye and be readily understood by an insured person who reads it. At the present time there is so much printed on the card, the type used is so small, that it is not to be wondered at if the great majority of insured persons have never read the rules, and often not even the slips attached to the card. Ample evidence of this is afforded by the number of insured persons with unsigned medical cards, who think they need only take them to a doctor for signature when they are ill.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Rear-Admiral G. L. Buckeridge to be Deputy Director-General of the Medical Department of the Navy vice Surg. Capt. C. V. Griffiths.

T. F. Davies to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS

R. H. Foster to be Lt. (on prob.). (From R.A.M.C., T.A., Supern. for serv. with O.T.C.)

The undermentioned Lts. (on prob.) are restd. to the estabt. : A. G. D. Whyte, R. A. Stephen, and M. J. Horgan.

ARMY DENTAL CORPS

Lt. A. N. Moon to be Capt.

RESERVE OF OFFICERS

Lt.-Col. C. W. Bowle, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

SUPPLEMENTARY RESERVE OF OFFICERS

Lt. J. N. Heales, from Somerset L.I. Supp. Res. of Off., to be Lt.

MILITIA

Maj. S. W. Hoyland retires on attaining the age limit, and retains the rank of Maj.

TERRITORIAL ARMY

Lt. T. T. P. Murphy to be Capt.

C. F. Critchley (late Offr. Cadet S. S., Univ. of Lond. Contgt., Sen. Div., O.T.C.) to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS

Capt. R. E. Davie, from Active List, to be Capt.

Lt. I. Mackintosh, from Active List, to be Lt.

Lt. E. L. Hancock to be Capt.

ROYAL AIR FORCE

Flight Lt. L. C. Palmer-Jones is promoted to the rank of Squadron Leader.

RESERVE OF AIR FORCE OFFICERS

Flight Lt. E. P. Carroll relinquishes his commn. on completion of service.

INDIAN MEDICAL SERVICE

Lt. R. I. Reid to be Capt.

BOGNOR WAR MEMORIAL HOSPITAL.—The annual report states that, in consequence of pressure upon the beds, extensions will probably be needed in the near future. There were 392 in-patients, whose daily cost was reduced from 9*s*. 10*d*. to 8*s*. 1*d*., the lowest figure since the hospital was opened in 1919. In the private wards no bed was vacant for more than a week. Income increased from £1465 to £3087, accounted for mainly by a larger volume of patients' payments.

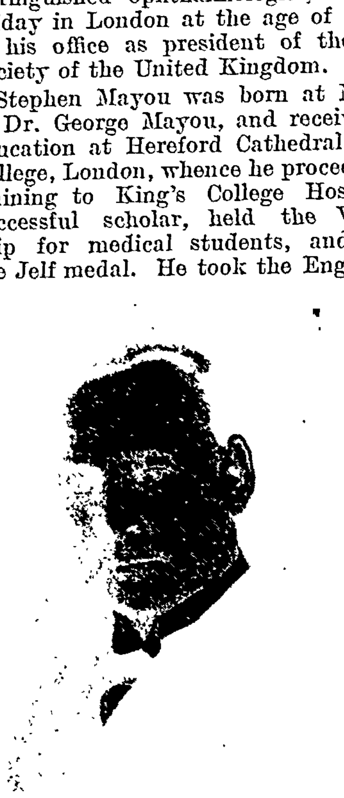
OBITUARY

MARMADUKE STEPHEN MAYOU, F.R.C.S.

PRESIDENT OF THE OPHTHALMOLOGICAL SOCIETY

We deeply regret to announce the death of this distinguished ophthalmologist, which occurred last Friday in London at the age of 58 and in the year of his office as president of the Ophthalmological Society of the United Kingdom.

Stephen Mayou was born at Monmouth, the son of Dr. George Mayou, and received his preliminary education at Hereford Cathedral School and King's College, London, whence he proceeded for professional training to King's College Hospital. He was a successful scholar, held the Warneford Scholarship for medical students, and gained, in 1896, the Jelf medal. He took the English double diploma in 1897, and in 1901 proceeded to the F.R.C.S. Eng. He served as house surgeon at King's College Hospital, and became assistant radiographer to the hospital and demonstrator of anatomy in the medical school. He then decided upon the specialty which he later followed with such fine results and in such a variety of public positions. He was appointed clinical ophthalmologist to his hospital as well as surgical registrar, and held also a clinical post in the ophthalmological department of the London Hospital. He became assistant surgeon to the Royal Eye Hospital at Southwark, and held the same post at the Seamen's Hospital at Greenwich. He was for a time at Moorfields, being chief clinical assistant at the Royal London Ophthalmic Hospital, and was also ophthalmological surgeon for different periods at the Children's Hospital, Paddington Green, and at the Hospital for Paralysis in Maida Vale. But the institution with which his name is principally associated was the Central London Ophthalmic Hospital, where he served over a long period as assistant surgeon, pathologist, and full surgeon, being the senior member of the staff at the time of his death.



MR. MAYOU

[*Photograph by Elliott & Fry*

In 1903 Mayou gained the Jacksonian prize at the College of Surgeons for an essay on the pathology and treatment of conjunctivitis in its protean forms, and in 1905 was a Hunterian professor at the College, while his contributions to the proceedings of the Ophthalmological Society now became regular, and of marked value. He was, indeed, one of the most frequent interveners in the discussions of the Society for the last 30 years, and his opinions were always listened to with interest, especially when those pathological questions were in debate where his experience was so wide and so varied. He was on the council of the Society for many years, served as secretary from 1916 to 1919 and as vice-president in 1932, and last year was elected president. At the last congress of the Society he was prevented illness on the first day from presiding, but his recepti on the second day demonstrated alike the high este ni which he was held and the opinion of the members that he had fully merited the leading position he had gained.

Mayou was not a profuse or frequent writer, but his handbook upon diseases of the eye, which went through three editions, the last appearing in 192 was seen to have features of practical value. This treatise was kept deliberately short, the author intimating that in his opinion the students' curriculum was already overburdened, but, while not pretending to give a complete account of diseases of the eye, it served to convey the essentials with which every medical practitioner should be familiar. He included in the book figures illustrating the microscopic appearance of such conditions as phlyctenular conjunctivitis and arterio-sclerosis of the retina, and proved that he had made himself a thorough master of this field of ophthalmology. A more widely known work is that which he wrote on ocular pathology in conjunction with his friend Treacher Collins, which embodied the results of their joint researches, and was excellently illustrated by figures, many of which were reproduced from original papers in the transactions of the Ophthalmological Society. This work, again, made no pretence to be encyclopædic but proved a most valuable handbook to ophthalmological specialists. On the death of Treacher Collins, Mayou succeeded him as medical officer to the White Oak Hospital, Swanley, an institution under the authority of the Metropolitan Asylums Board for the treatment of children up to ten years of age suffering from ophthalmia and other contagious diseases of the eye; he was also visiting ophthalmic surgeon to St. Margaret's Hospital, run, under the same authority, for the treatment of ophthalmia neonatorum. In both of these institutions he found time to give valuable service, although it was always the Central London Ophthalmic Hospital which absorbed his main attention.

Mr. Leslie Paton writes: "Others can write of the distinguished scientific and clinical work that Mayou has done. I should like to be allowed to say just a few words about another side of his work which has proved of the greatest value to British Ophthalmology but which is, as a rule, only too little recognised, work done on councils, committees, and subcommittees. Only those who were associated with him in these too often thankless tasks know how faithfully he did anything he undertook to do. He served on the editorial committee of the *British Journal of Ophthalmology* from its initiation in 1917. That involves, as a rule, two meetings a month. He was one of the earliest members of the Council of British Ophthalmologists and, in addition to being treasurer, served on many of its committees. Only three days before his death he attended a meeting of the executive committee and almost the last letter he wrote on the evening before he died dealt with its work. He was at various times member of the council, secretary, and vice-president of the Ophthalmological Society of the United Kingdom and I am sincerely thankful that he lived to achiev the highest honour in British ophthalmology, the post of president of that society. It is only too difficult to find men willing to give their time and energy to committee work of that type which brings little credit or honour to the individual worker, but n its way as essential as the more showy scientific clinical work, and it is only an ordinary truth to y that on all these committees the place that Mayou upied will be difficult to fill. Whether on the golf urse, the riverside, or in the quietude of social life was a charming companion. A slight occasional t characteristic hesitancy of utterance served only draw attention to the clearness of his thinking d the lucidity of his expression. In all ways he lfilled the dictum of our first president, Sir William owman, and by his life's work advanced the science ophthalmology."

FREDERICK DITTMAR, M.D. Glasg., D.P.H. Camb.

ATE SENIOR MEDICAL INSPECTOR, LOCAL GOVERNMENT BOARD FOR SCOTLAND

THE death occurred on July 16th of this well-known uthority on public health, who retired from his fficial post in the Department of Health for Scotland n February last at the age limit. He died somewhat uddenly at his house in Newbury, Berkshire, where he had just established himself.

Frederick Dittmar was born in Edinburgh, his ather, the author of a well-known text-book, who later became professor of chemistry at Anderson's College, Glasgow, being at the time on the scientific staff of the University of Edinburgh. The son received his education, general and professional, at the University of Glasgow, where he graduated as M.B., C.M. in 1893, proceeding to the doctorate with honours three years later. He now spent a period in Vienna and acquired German as a native language, an accomplishment which stood him in good stead later. He became house surgeon and house physician to the Victoria Infirmary, Glasgow, and acted as assistant medical officer in charge of the Fever Hospital. He left Glasgow for a time to serve as M.O.H. at Scarborough, but returning to Glasgow was appointed by Dr. Burn Russell, then M.O.H. of the city, upon his staff. While serving with Dr. Russell he had particular opportunities for the study of small-pox questions from the public aspect; and he also acted as assistant medical officer to Glasgow Prison. During the first outbreak of plague in Glasgow he also gained unusual clinical experience through his coöperation during the epidemic with the late Dr. John Brownlee, the well-known statistician, who was then superintendent the Belvedere Hospital.

DR. DITTMAR

Dr. Russell became medical member of the L.G.B. r Scotland, and was succeeded on his death in 1904 by Sir Leslie Mackenzie, the first medical inspector under that Board. Dittmar then succeeded Sir Leslie, and when the Board was amalgamated in 1919 with the Scottish Insurance Commission, thus becoming the Scottish Department of Health, Dittmar was appointed to the Department, having full familiarity with every phase of public health. His intention to remain in touch with systematic medicine was manifested by his sitting, at a much later age than usual, for the examination for the M.R.C.P. Edin.; later he became F.R.C.P. Edin., and acted as an examiner for the College on more than one occasion. At the Board he did admirable work, in particular when he took charge of the infectious diseases hospitals of Scotland. He made many special inquiries and was untiring in his energies, and his brief but concentrated report on the Island of Lewis and the conditions of housing there was the start—the somewhat sensational start—of a reform movement which has never stood still. In the later years of his service he acted frequently as medical assessor at housing inquiries under the new Acts. While he wrote no systematic book he published valuable papers upon many public health matters, notably one on slaughter houses and meat inspection; another, in coöperation with Brownlee, on the administrative treatment of scarlet fever, or rather of undefined cases diagnosed as such; and a third on the control of small-pox. In his writings, as in his official actions, he was a sound though friendly critic; his judgment was widely appreciated.

Dittmar was highly popular with his staff, who entertained him at luncheon on his retirement and made him a present of books. His death was unexpected, and occurred when he appeared to have a pleasant phase of retirement before him. The photograph which is reproduced here shows him in young middle life, no more recent portrait being available. He leaves a widow, a distinguished classical scholar, and three daughters, one of whom is a medical student.

JAMES WILLIAM STEEL, M.B. Edin.

THE death of Captain J. W. Steel, of Bournemouth, at St. Bartholomew's Hospital on July 14th, will be felt by many who served with him on the Salonica front during the war. Having graduated in medicine at Edinburgh in 1913, and held a resident post at Bolton Infirmary, he joined the R.A.M.C. and was attached to the 28th General Hospital on the Monastir Road where, writes one of his war-time colleagues, his ability as a physician and his genius for music made him an outstanding figure in the mess, the wards, and at the concerts given to entertain the men. "Jimmy Steel," he adds, "was regarded with universal affection; every man, woman and child who came into contact with him had a good word for him." After the war Steel put up his plate in Bournemouth and became a popular practitioner there.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, last year admitted 6725 in-patients and treated 28,484 out-patients, a considerable reduction in each category. The annual report suggests that these reductions are probably attributable to the higher standard of health prevailing throughout 1933, a view borne out by the similar experience of many other hospitals. There was an adverse balance on the year of £11,698, which would have been much greater but for the receipt of £17,667 in legacies. The rebuilding fund makes slow progress; £11,655 was collected last year. In-patients cost £4 1*s.* 1*d.* each per week; out-patients cost 8*s.* 9*d.* each. The new nurses' home in Guilford-street is now completed and ready for occupation. It is a seven-floored building on the site of 13 houses, and contains accommodation for 156 nurses. Eventually there will be an extension provided by the demolition of three other houses, to include the preliminary training school for nurses.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Housing Policy: The Question of a Housing *Commission*

IN the House of Lords, on July 18th, Lord BALFOUR OF BURLEIGH moved the following motion:

> "That in the opinion of this House the provision of one million houses to be let at a weekly rental, inclusive of rates, of 10s. and under, in addition to the slum clearance proposals of the Government, is an urgent national need, and to request the Government to consider the desirability of setting up forthwith, under the authority of the Minister of Health, a Housing Commission armed with all necessary powers, and charged with the specific duty of securing the erection of such houses by local authorities and public utility societies on a national plan and with the minimum of delay."

He said that the intentions and desires of the Government in regard to housing were excellent, but there was a danger of the failure of the Government's programme through lack of a coherent plan. They knew of the plan for slum clearance and they were told that there was coming a plan for dealing with overcrowding, but they have not yet been told of any plan for additional new houses to let at low rents, and he thought that the Government had tackled this problem from the wrong end. It was, he said, now admitted as a principle, to which the Government was almost prepared to agree, that the provision of a certain standard of housing accommodation for every family at a rent within the family capacity to pay must as an ultimate aim be accepted as a national duty and a public responsibility. Housing was by far the most important of the social services.

There had been eight Ministers of Health since the war, and still they had not found out what the task was with which they were faced and which they had to accomplish. That seemed to be one of the strongest arguments for the *establishment of a Housing Commission*. In the provision of a million houses there were certain factors to be taken into account. First of all there was the excess of families for the number of available houses. That excess of families had increased in the last census period, and was now over a million. He knew that was *subject to qualification.* There was also the degree of overcrowding. The Registrar-General's figures gave, he thought, 2,600,000 people living more than two to a room—admittedly an excessively high standard. More houses were needed for them. Then there was the estimated future increase in *the number of families.* Economists said that it would amount to 600,000 more families in the next ten years. There was also the progressive deterioration and wearing out of the houses.

Lord Balfour said he regarded a million houses at 10*s*. a week as a conservative estimate of the requirements. If that was so, the Government would have to adopt a totally new point of view. It was necessary to make a plan and secure the advantage of long-scale planning. The provision of a million houses would cost £350,000,000 or £400,000,000 spread over the necessary period. He was not afraid of that. Money could easily be raised by the Government at about 3 per cent. There should be a guarantee to provide cheap money inasmuch as that was far cheaper than a subsidy. The Government was open to criticism also on their attitude towards private enterprise. It was common ground that private enterprise now could not provide houses at the required standard to let at 10*s*. a week. What was needed was continuity in housing policy and continuity in plan. If a housing commission had been set up in 1919 some of the mistakes of the past would have been avoided, and if it was set up now new mistakes, which would otherwise be made, would be avoided. What he was suggesting was not a colossal bureaucracy but a central *constructive organising* brain to view the whole thing from a national point of view.

Lord AMULREE said that although very substantial progress *in housing had been made since* 1919, and much money had been expended both by the Exchequer *and the local authorities*, the various schemes had made little or no provision for the lower paid worker who was still left in the slums and overcrowded houses. The real measure of overcrowding was to be ascertained on the basis of living accommodation per person.

Two persons to a room was a low standard; the minimum standard was generally regarded as an average of one and a half persons to a room. The London County Council on its building estates observed a standard of one and a quarter persons per room. If they took an average of one and a half persons to a room they found some very striking results. According to the census of 1931, 2,630,000 persons lived more than two to a room. The additional accommodation required to rehouse them at one and a half persons to a room might be estimated at a further million rooms, or 250,000 houses—probably 300,000 houses if they allowed for the segregation of the sexes. Competent observers considered that the number of families might be expected to increase at an enhanced rate compared with the increase of population. Further, many of the present houses were gradually wearing out, and according to his information there would probably be a wastage of about 30,000 houses per annum for the next 15 or 20 years.

If, said Lord Amulree, they took all these other factors into account it was estimated that 1,900,000 houses must be provided during the next ten years to house families separately and at least 1,000,000 of these must be provided at inclusive rentals of 10*s*. a week and under to supply the needs of the lower paid workers. For this nation-wide undertaking a special Board such as a Housing Commission would make for continuity of policy, almost impossible under the present system with some 1800 local authorities.

The Earl of LISTOWEL said that the report of the Amulree Committee on Housing came at an extraordinarily opportune moment, and he urged the Government to embody in their own Bill certain of its outstanding recommendations. The Labour Party, to which he belonged, believed that over a period of ten years 2,000,000 or 3,000,000 new working-class houses should be built.

The Earl of CRAWFORD said there were scores of thousands of new houses in London to-day infested with vermin. The bed-bug was the real health problem in thousands of houses, and it was rapidly extending. The bed-bug was a most dangerous creature; it produced restlessness and troubled sleep which in course of time led to debility and general ill-health. The owners of these new blocks of infested property were now the sanitary authorities, and the Government should not rush their building *programme* unless they had *tolerable assurance that the* new houses in a year or two would not be infested with this curse. Further, they should not immediately begin to rebuild upon a cleared slum area.

GOVERNMENT STATEMENT

Viscount HALIFAX, president of the Board of Education, replying to the debate, said that he would take steps to see that the concrete proposals made by Lord Crawford in regard to bug infestation were brought along with other points raised in the debate to the notice of the Minister of Health. In regard to the proposal for setting up a Housing Commission he *found it* hard *to believe that the rapid execution* of a housing policy would be facilitated by interposing a new body between the Minister and the local authorities upon whose intimate, rapid, and cordial coöperation all housing policy must ultimately and entirely depend. For the most part all the field and scope of work contemplated for the Commission was exactly what was being done to-day by the Ministry of Health; no one had said that that Department was not doing it properly. The existing *position* was one in which local authorities were charged with the duty of considering and submitting proposals for working-class houses in their areas, as they were charged with the further duty of abolishing and replacing slums, and under legislation to be forthming, he understood they were to be charged with similar duty in regard to the elimination of over-owding. Therefore the principle stated in the mulree Committee's report was the basis of the resent Government policy.

As to whether the object of policy should be, as Lord lfour of Burleigh's motion suggested, the production of million houses to let at inclusive weekly rentals of 10*s.*, did not believe that the solution of the housing problem as facilitated by round statements of doubtful validity. He thought that the calculations on which the figure of ,000,000 houses appeared to be based were very far from eing secure. That figure was subject to various deductions, he upshot of which must be that the number of houses equired to be provided at these rents on the committees' wn calculation would be very much less than the suggested 1,000,000. He hoped Lord Balfour would not press as he primary object of housing policy the provision of a definite number of houses, whether 1,000,000 or any other. The principle of such a policy had been tried by successive Governments during the last 15 years and had been discarded as unsound. The present Government policy was rather that of providing, in accordance with an ordered plan, whatever number of houses might be needed to overcome the evil that rightly moved the country to indignation, and to do that by beginning with a direct attack on the conditions which were the most intolerable. Already local authorities had submitted plans for the demolition of all houses which they had found in their areas to be unfit for habitation, and for the provision of accommodation to replace them at low rents. During the next five years 280,000 houses unfit for human accommodation would be swept away, and 294,000 houses would be built for those who were now forced to live under intolerable conditions.

At the end of five years, said Lord Halifax, there would, as they hoped, except in a few towns where a longer period was necessary, be no more slums. In the coming autumn the Government would propose to Parliament legislation to define standards of accommodation and to provide a sufficiency of houses to enable those standards to be observed. These proposals would involve re-housing and re-planning on a scale which it had never yet been possible to contemplate in this or any other country. The Government proposed as an integral part of the next stage of their housing policy to appoint a strong Advisory Committee to which the Minister of Health would be able to refer at all stages for advice on the problems still to be solved.

Lord Balfour said Lord Halifax's statement had given him and his friends a substantial degree of satisfaction. He asked leave to withdraw his motion, which was given.

Housing in Scotland

On July 18th, in Committee of Supply, Mr. Skelton, Under-Secretary of State for Scotland, said that 1933 was a record year for the number of houses completed with State assistance. The number of houses completed under all the Acts was 20,915. For the first six months of 1934 there was again a record, the number of houses completed with State assistance being 11,850. The Government had not been content with attempting to concentrate the attention of local authorities on slum clearance merely by legislating; they had attempted, not without success, to institute a real drive in administration, and in every other way, towards the development and acceleration of slum clearance programmes. The estimated number of uninhabitable houses in Scotland was 61,200 and the local authorities' programmes, mostly fixed, but some still provisional, proposed during the five-year period to build 56,394 houses, or over 92 per cent. of the total number recognised as uninhabitable. Some small proportion of the 61,000 houses might be capable of being reconditioned. The next stage of their programme was to deal drastically, and he hoped finally, with overcrowding. In Scotland about 15 per cent. of the population lived three to a room. The English figure was only about 1·5 per cent., so that here they had a special Scottish problem.

Motor Noise and Public Health

The Road Traffic Bill was further considered by the House of Lords in Committee on July 19th, when Lord Elton (in the absence of Lord Horder) moved a new clause providing that it should be an offence under the principal Act to sell, or to offer for sale or supply, a motor vehicle or trailer for use on the road in this country with an inefficient silencer. The facts of the present situation were, he said, simple, but rather startling. It was already illegal to use on the roads a motor vehicle with an inefficient silencer, but it was not illegal to supply such a vehicle. Under the Road Traffic Act 1930 it was provided that motor vehicles should be equipped with efficient silencers, but this regulation was openly and deliberately flouted.—The Earl of Plymouth, for the Government, said he did not think the solution was quite as easy as was suggested. The present difficulty of enforcement was largely due to the lack of practical means of quantitative measurement of noise, and the special committee of the Department of Scientific and Industrial Research were being asked to consider that point. So soon as definite and adequate " performance specifications " could be laid down, the Minister under the powers which he already possessed would not hesitate to include them in the regulations.—The Earl of Crawford said it might take a long time to settle the methods of quantitative measurement of noise, and meanwhile it would be an encouragement if the Ministry conducted prosecutions against people who left their cars roaring in the street at two o'clock in the morning.—The Marquess of Salisbury said that when, as Lord Horder had told them, this evil was really antagonistic to the public health the time had arrived when something ought to be done.—Lord Jessel thought it did not need a departmental committee to say what was noise and what was not.—The new clause was agreed to.

In the House of Commons on Friday, July 20th, the Domiciliary Nursing Services Bill was read a second time.

Malnutrition in School-children

On a Vote of £28,110,018 (including a supplementary sum of £1,506,000) to complete the sum necessary to defray the salaries and expenses of the Board of Education,

Mr. West moved to reduce the Vote by £100. He said he understood that there were roughly 2,000,000 children in this country between two and five years of age, and of these children 200,000 came from overcrowded or slum homes. It had been pointed out by Sir George Newman year after year that what was wanted was more nursery schools. Last year there were only 58 in the whole country, whereas the number needed must be at least 250.

Miss Rathbone said that an attempt had been made by the Parliamentary Secretary to the Board of Education and by officials to lull the public conscience to rest on the subject of malnutrition. It was maintained first that there was no widespread malnutrition among school-children; and, secondly, that the arrangements for feeding necessitous school-children were sufficient to cope with such malnutrition as existed. Both these assurances were, on the face of them, incredible. There had been lately several inquiries into minimum subsistence needs and the cost of supplying those needs, and every one of those inquiries had produced a scale of needs and an estimate of the cost of supplying them such as could not possibly be realised by a family with several children permanently on unemployment pay, or even by an agricultural labourer or a lowly paid town labourer. She believed the school medical staff were wrong when they said that only 1 per cent. of children were suffering from under-feeding. The routine medical examination took place three times in a child's school life—at 5, 8, and 12 years of age. How could malnutrition be tested in that way It might be urged that it was the business of a school teacher to note preliminary symptoms of malnutrition and report them to the head teacher, who, if he thought necessary, would send the child for a special medical examination. But were the school teachers competent to do that? They were not medically trained. If it was not possible to examine the children medically more frequently, surely they could be measured and weighed. Not nearly enough use was made of school nurses. Arrangements could be made with the local nursing associations. The tests and standards of school medical inspection should be much more carefully regulated and standardised. But even if all this were done she did not believe that they would arrive at a satisfactory test of malnutrition. The proper way to deal with the problem was to adopt a scientific income test worked out by the Board of Education. If the income scale was worked out for the country as a whole, and every child whose parents came below that scale was given free meals, they would know that there would not be a single underfed child, except where the under-feeding was the parent's fault, and then pressure could be brought to bear through the law.

Mr. RAMSBOTHAM (Parliamentary Secretary to the Board of Education), replying to the debate, said that he could not help feeling that having regard to the difficulties of the position and the complexities of the diagnosis the medical officer was just as well qualified to express an opinion on the question of malnutrition as Miss Rathbone. Any department which desired to get the best evidence and expert opinion must take note of the opinion expressed by the medical officers and the reports of school teachers. He thought that Miss Rathbone would do a great deal more good for the cause to which she was devoted by using her great influence to impress on all concerned the necessity for a better understanding of the diet given in homes. One of the great difficulties of medical officers was that when children came to them showing signs of malnourishment, or under-nourishment, it was not always due so much to poverty in the home as to improper and inadequate diet.

The motion to reduce the Vote was rejected by 178 votes to 39.

Sir G. COLLINS (Secretary of State for Scotland), speaking on a Vote of £4,106,935 for the salaries and expenses in connexion with public education in Scotland, which was discussed by the House of Commons in Committee of Supply on July 18th, said that although the reports of the school medical officers and medical officers of health had conveyed no signs that malnutrition among school-children was increasing, one could not ignore the fact that malnutrition did exist. He was advised, however, that defective nutrition was not merely a question of lack of food, but might be largely due to the use of foodstuffs which did not produce good bodily structure and resistance to disease. If that were so, consideration might have to be given to the question of instructing the people in what he might term "the elements of nutrition." It was better to build up healthy children capable of resisting disease than to spend money on the treatment of diseases which could be prevented by proper diet.

Road Traffic Bill

In the House of Lords on Tuesday, July 24th, the Road Traffic Bill passed through the Report stage.

Duty on Artificial Teeth

In the House of Commons on July 24th, Dr. BURGIN, Parliamentary Secretary to the Board of Trade, moved that they House should approve of an Order made under the Import Duties Act, imposing an additional duty on artificial teeth.

Mr. RHYS DAVIES said he believed that the duty would amount to about 1½*d.* per tooth, and he would like to know whether a request for the duty had come from the dentists or from the manufacturers of teeth in this country.

Dr. BURGIN said that there were some 30 million artificial teeth used every year in this country. Ten millions were manufactured at home and about 20 million were imported. The British industry was in a position to meet the whole of the requirements of modern dentistry in this country and to supply all United Kingdom users with teeth of home m facture. The imported teeth came from the U States of America, Palestine, Germany, France, recently from Japan. The highest duty payable a single tooth was just under 1¼*d.* The lowest payable for an operation which involved the of a single tooth under the National Health Insuran Acts was 5*s.*, and a duty which could not in an circumstances amount to more than 1¼*d.* a too would not increase the cost of a denture to t consumer by a single fraction.

Mr. DAVIES asked whether an agreement had b come to with the dentists to that effect.

Dr. BURGIN said that the committee which h examined this matter were of opinion that th increase in duty would not affect the price paid b the consumer.

The motion was agreed to.

HOUSE OF COMMONS

WEDNESDAY, JULY 18TH

Pedestrian Crossing Places in London

Mr. CURRY asked the Minister of Transport if, in vie of his recent experiences in using the pedestrians' crossi in London, he could now make any statement whi would result in more public advantage being derived fro them.—Mr. HORE-BELISHA replied: The experience so far gained with pedestrian crossing-places which have been marked at a number of road junctions in London is sufficiently satisfactory to justify the extension of the scheme to other localities, and I am making proposals f such extensions to the highway authorities concerned.

Spirits for Medical and Scientific Use

Dr. SALTER asked the Chancellor of the Exchequer the quantity of spirits used respectively for the manufacture of recognised medical preparations, or for scientific purposes, in respect of which a rebate of duty was granted under Section 4 of the Finance Act, 1918, as amended, during the latest available financial year.—Mr. DUFF COOPER, Financial Secretary to the Treasury, replied: The quantity of spirits upon which rebate was paid under Section 4 of the Finance Act, 1918, as amended, during the year ended March 31st, 1934, on the ground that the spirits were used in the manufacture or preparation of recognised medical preparations, or for scientific purposes, was 584,000 proof gallons. Information is not available as to the quantities used under the respective heads.

THURSDAY, JULY 19TH

Unemployment Insurance Statutory Committee

Mr. THORNE asked the Minister of Labour is he could now state the name of the chairman and the names of the other members of the statutory committee under Part I. of the Unemployment Act; and what salary the chairman, the vice-chairman, and the other members of the committee were to receive.

Mr. LAWSON asked a similar question.—Mr. O. STANLEY replied: The members of the Unemployment Insurance Statutory Committee are: Sir W. H. Beveridge, K.C.B. (chairman); Mr. A. L. Ayre, O.B.E., J.P.; Mr. A. D. Besant, B.A., F.I.A.; Captain the right hon. C. C. Craig, P.C. (Irel.), D.L.; Mr. A. Shaw, J.P.; Miss Katharine J. Stephenson, C.B.E., J.P.; and Mrs. M. D. Stocks, B.Sc. (Econ.), J.P.

The chairman will receive a salary of £1000 per annum, and the other members' fees of five guineas for each day spent in attending a meeting, subject to a maximum of £500 in a year. No member will be required to give full time to the work of the committee.

Refuse Disposal in London

Sir FRANCIS FREMANTLE asked the Minister of Hea if he had now received the report from the adviso committee on the disposal of London refuse, and when it would be published.—Sir HILTON YOUNG replied: I understand that the interim report is likely to be received before the end of the present month. I am not in a position to make any statement as to publication.

Institutions for the Deaf and Dumb

r. **Caporn** asked the Minister of Health how many ty or county borough councils had applied for per ion to contribute towards the support and maintenance stitutions for deaf-and-dumb persons; and whether ould state the names of such councils and, in each , the amount of the proposed subscription and the on taken by him in connexion with such application.— **Hilton Young** replied: Thirty county or county ough councils have applied during the past year for consent to the payment of subscriptions to missions the deaf and dumb, and I understand that at least e other councils are paying annual subscriptions to h missions. I will send my hon. friend a statement ing the names of the councils and the amounts of the scriptions, and showing what action has been taken each application. In those cases in which sanction s not yet been given to the proposed subscriptions, am making further inquiries as I am not at present isfied that the councils in question have given adequate nsideration to the needs of the missions in respect of the cement of deaf-and-dumb persons in employment.

Mr. **Caporn** asked the Minister of Health whether he s satisfied that local authorities were making as wide a e of the powers provided under Section 67 (6) of the or Law Act, 1930, as was desirable in the public interest; hether he had received adequate response to his circular o. 1337, dated May 22nd, 1933; and whether he would onsider the desirability of extending the provisions of ections 2, 3, and 4 of the Blind Persons Act, 1920, to eaf-and-dumb persons.—Sir **Hilton Young** replied: he answer to the first two parts of the question is in the egative. I am, however, taking action with a view to ecuring closer attention by the local authorities to the uggestions made in the circular mentioned by my hon. riend, and as at present advised I do not consider that resh legislation on the lines he suggests is desirable.

Imported Liquid Eggs

Lieut.-Colonel **Acland-Troyte** asked the Minister of Health whether he had any information to show that the United States of America, or any other countries, prohibited the importation of liquid eggs on grounds of health; and whether he would consider prohibiting their importation to this country on these grounds.—Sir **Hilton Young** replied: The answer to the first part of the question is in the negative. Liquid eggs imported into this country and intended for food must be free from preservatives and fit for human consumption, and, subject to those conditions, I am not aware of any reason for prohibiting their importation on grounds of public health.

Temperature in the House of Commons

Mr. **Bernays** asked the First Commissioner of Works whether he would examine the possibility of fitting electric fans in the chamber in order to produce a cooler atmosphere during the summer months.—Mr. **Ormsby-Gore** replied: The air is already drawn through this chamber by means of electric fans which could be speeded up if necessary, but I fear that the draughts created thereby would inconvenience hon. Members. The installation of electric fans in the chamber itself would only create draughts without reducing the temperature, which during the recent warm weather has never exceeded 71° F. To reduce the temperature further without increasing the humidity of the air to an uncomfortable point would involve provision of plant at a cost of some £4000 or £5000, in addition to running costs of some £500 per annum; and I should be disposed to doubt whether conditions as they exist are such as to warrant expenditure of that order.

Ribbon Development and Road Accidents

Mr. **Cadogan** asked the Minister of Transport whether, in view of the continued increase of road accidents, it was s intention to introduce legislation dealing with ribbon velopment on the main roads at an early date.— . **Hore-Belisha** replied: I am devoting attention to this question in conjunction with my right hon. friend the Minister of Health, and my hon. friend will not expect me to make any statement as to legislation.

Imports of Dental and Medical Appliances

Mr. **Lennox-Boyd** asked the President of the Board of Trade if his attention had been drawn to the fact that the imports of dental, surgical, medical, and veterinary instruments and appliances (except optical) had increased from £163,813 in the first half of 1932 to £215,250 in the first half of 1933, and to £247,022 in the first half of 1934; and what further steps he proposed to take to protect the British industry manufacturing these scientific goods.—Dr. **Burgin**, Parliamentary Secretary to the Board of Trade, replied: I am aware of the facts to which my hon. friend draws attention. Any question of an increase in the duty on these goods must be dealt with by the ordinary procedure under the Import Duties Act.

MONDAY, JULY 23RD

Tarred Roads and Cancer of the Lung

Mr. **Clarry** asked the Minister of Health whether his department had any evidence that cancer of the lung might be caused by dust from tarred roads; and if there were any known fatal cases of lung cancer attributable to this cause.—Mr. **Shakespeare** (Parliamentary Secretary to the Ministry of Health) replied: My right hon. friend is advised that a relation between the inhalation of dust from tarred roads and cancer of the lung has not been established, and it is, therefore, not possible to say whether any deaths from this disease can be attributed to this cause.

Sir A. M. **Samuel** asked if the Minister had any record or information showing why there were these great increases in the number of recorded cases of cancer of the lung.

Mr. **Shakespeare**: I would not put it as high as that. The percentage of cancer of the lung is very small.

Sir **Francis Fremantle** asked if the Minister was aware that the number of deaths from cancer of the respiratory organs was only 90 per million, compared with 1500 altogether from cancer generally.

TUESDAY, JULY 24TH

Food Poisoning in Lincolnshire

Mr. **Thorne** asked the Minister of Health whether he could give any information to the House in connexion with the 100 people living in Lincolnshire villages who were suffering from an illness caused by some kind of food poisoning; and whether he had received any information from the hospital authorities about the matter.—Mr. **Shakespeare**, Parliamentary Secretary to the Ministry of Health, replied: My right hon. friend has received reports from the district and county medical officers of health, who state that about 30 persons in the Welton Rural District were affected but that all have now recovered. The cause of the outbreak has not been established, but some pickled meat is suspected.

Grants for Rural Water-supplies

Mr. **Wells** asked the Minister of Health the total amount granted in respect of rural water-supplies to date.—Mr. **Shakespeare** replied: Grants to the total of £132,500 have been provisionally allocated in respect of schemes for 361 parishes estimated to cost £1,037,000.

Medical Practitioners and Economy Measures

Mr. D. G. **Somerville** asked the Minister of Health what arrangements had been made up to date to restore in part to doctors and chemists the losses suffered by them as a result of the economy measures in 1931.—Mr. **Shakespeare** replied: I am sending my hon. friend a copy of a circular which was issued by my department to insurance committees on June 20th, setting out the arrangements for giving effect to the decision of the government to restore, as from July 1st, one-half of the deduction made from the remuneration of insurance practitioners and chemists, as a measure of economy, from Oct. 1st, 1931.

Official Pensions and Salary Cuts

Sir **Herbert Samuel** asked the Chancellor of the Exchequer which were the classes of persons in the service of the Crown or local authorities the amount of whose pensions would be diminished through the fact that their pensions were assessed on rates of salaries which would have been affected by the temporary cuts in salaries or grants made by Parliament in 1931.—Mr. **Chamberlain** replied: Among the main classes in question are the following: Local Government Officers, in so far as they have been subjected to an economy cut and have not been permitted to contribute on and to be pensioned on their uncut salaries under the London Local Authorities Superannuation (Temporary Provisions) Act, 1932, and the Local Government and Other Officers' Superannuation (Temporary Provisions) Act, 1933. As regards Civil Servants and others whose pay was subject to periodical variation by reference to the cost-of-living figure, their pensions have been calculated as from July 1st, 1931, the basis of a cost-of-living figure of 50 in accord [illegible] with the provisions of a Treasury Minute dated March [illegible] 1922 (House of Commons Paper 55 of 1922). The fig [illegible] of 50 for calculation of pensions was fixed in June, 1 [illegible] not as part of the emergency measures in the aut [illegible] of 1931.

MEDICAL NEWS

British Industries House: Medical Section

The opening of the Medical Section of the British Industries House, announced in our columns last week, proved a popular function. The Section was opened by Lord Derby, who said that the movement made particular appeal to him as head of the Travel Association, while he emphasised his belief that those who came to this country for pleasure would be more readily induced also to do business if a convenient centre were furnished. Here, he said, was such a centre from which hospitals could draw practically all that they required. The meeting was crowded, over two thousand persons being present and, on all hands, it was agreed that the display showed the British manufacturer to be alive in a comprehensive manner to the material needs of hospitals, whether those needs were manifested by the demands of the staff, the amenities of the patients, or the facilities for scientific progress.

University of London

At recent examinations the following candidates were successful:—

POST-GRADUATE DIPLOMA IN BACTERIOLOGY

Mary C. Baker, D. N. Chakravarti, S. C. Ghosal, Gareth P. Gladstone, Vladimir Glass, P. P. Grigg, Betty C. Hobbs, G. W. Rea, and F. C. Storrs.

DIPLOMA IN MEDICAL RADIOLOGY

W. M. Hewetson, Patrick Hogan, S. R. G. Pimm, A. M. Vlok.

Dr. J. H. Gaddum has been appointed to the university chair of pharmacology at University College as from July 1st, 1935. He succeeds Prof. E. B. Verney.

Since the beginning of this year Dr. Gaddum has been professor of pharmacology in the Egyptian University, Cairo. An arts graduate [illegible] d as M.R.C.S. from University College [illegible] ıg the staff of the National Institute [illegible] 1927, he worked at first on thyroxin [illegible] in collaboration with Prof. [illegible] ıssociated with Dr. H. H. Dale in his [illegible] ration of acetylocholine at nerve-endings, [illegible] ed the physiological behaviour of vaso- [illegible] ı U. von Euler (Stockholm), H. C. Chang [illegible] (Münich), and others. The general result of this work was to suggest that acetylcholine—or some related choline ester—is the chemical transmitter of the effects of nerve impulses, nc [illegible] tion of neoarsphenamine.

Dr. J. R. Marrack has been appointed to a new chair of chemical pathology tenable at the London Hospital Medical College.

Dr. Marrack was born in 1886 and educated at Blundell's School. He graduated in me [illegible] ın 1912 and held the John Lucas Walke [illegible] . C. Brown research scholarship, and a [illegible] was elected a fellow of St. John's Colleg [illegible] lecturer in chemical pathology, making investigations of metabolic disorders in relation to arthritis. Joining the Royal Army Medical Corps in 1914, he served with distinction throughout the war, being mentioned in despatches and receiving the D.S.O. and M.C. In 1919 he became chemical pathologist to the London Hospital and lecturer in chemical pathology in the medical college. With Dr. P. N. Panton he is the author of a text-book, "Clinical Pathology." His later work finds its justification in a valuable report to the Medical Research Council on "The Chemistry of Antigens and Antibodies." This was reviewed in a leading article in THE LANCET of Feb. 24th last.

University of Wales

At recent examinations the following candidates were successful:—

M.D.

A. R. Culley and W. Phillips.

M.B., B.CH.

Alice D. Alban, T. A. Blyton, Enid G. Fisher, M. E. Gordon, R. W. Griffiths, Ira B. Lawrence, and S. R. Saunders.

Society of Apothecaries of London

At recent examinations the following candidates wer [illegible] successful:—

Surgery.—F. G. S. Alderson, Univ. of Leeds; G. W. Bende [illegible] St. Mary's Hosp.; J. T. Boocock, Univ. of Leeds; J. A [illegible] McClintock, King's Coll. Hosp.; A. J. McGuire, Charing Cr [illegible] Hosp.; H. J. Ripka, London Hosp.; and F. W. Treadwe [illegible] Univ. of Birmingham.

Medicine.—F. G. S. Alderson, Univ. of Leeds; J. A. Amc [illegible] St. Mary's Hosp.; and S. M. Sabet, Welsh National Scho [illegible] of Medicine, Cardiff.

Forensic Medicine.—T. D. R. Aubrey, Univ. of Oxford a [illegible] Bristol Royal Infirmary; J. W. D. Bull, Univ. of Cambridge and St. George's Hosp.; W. C. Campbell, Univ. of Birmingham; D. S. G. Genge, Univ. of Cambridge and St. Thomas's Hosp.; S. Klein and J. E. T. Munn, St. Mary's Hosp.; S. M. Sabet, Welsh National School of Medicine, Cardiff.

Midwifery.—T. D. R. Aubrey, Univ. of Oxford and Brist [illegible] Royal Infirmary; J. W. D. Bull, Univ. of Cambridge and St. George's Hosp.; G. W. Bender, St. Mary's Hosp.; C. C. Joannides, Univ. of Graz and Westminster Hosp.; S. J. Navin, St. Mary's Hosp.; J. C. Paterson, Univ. [illegible] St. George's Hosp.; and J. F. L. Walley, Ur [illegible] and St. Mary's Hosp.

The following candidates, having completed [illegible] tion, are granted the diploma of the society [illegible] practise medicine, surgery, and midwifery: S. Klein, A. J. McGuire, and H. J. Ripka.

University of Glasgow

The King has approved the appointment of Dr. Samuel James Cameron to be regius professor of midwifery in succession to Prof. J. M. Munro Kerr who retires on Sept. 30th.

Dr. Cameron is obstetric surgeon and gynæcologist to the Glasgow Maternity and Women's Hospital, and consultant to several other hospitals in the city and locality. He graduated as M.B. at Glasgow University in 1901 and after holding posts in the anatomical school and in hospital, became assistant to the regius professor of midwifery. Joining the staff of the Western Infirmary, he wrote [illegible] subjects. Appointment to the Glasgov [illegible] followed, and Dr. Cameron was elected [illegible] became university lecturer in clinical [illegible] producing his "Manual of Gynæcology, [illegible] Manual of Obstetrics." Accounts of hi [illegible] evention of toxæmia in pregnancy have lately appeared in our own columns (1932, ii., 731) and elsewhere. Dr. Cameron is a fellow of the British College of Obstetricians and Gynæcologists and an examiner for the Scottish Central Midwives Board.

University of Edinburgh

On July 18th the following degrees and diplomas were conferred:—

M.D.—W. J. Candlish, J. R. Davidson, F. A. Duffield, Phyllis M. Edwards, *Annie E. Ferguson, W. H. Gillespie, *R. G. Hood, *H. L. Khosla, J. L. Law, *W. V. Macfarlane, S. L. A. Manuwa, *James Milne, W. E. Orchard, Robert Porteous, D. M. Scrimgeour, and **C. E. Van Rooyen.

C.M.—*H. J. P. Brüwer.

* Commended for thesis.

** Highly commended for thesis.

Ph.D.—B. B. Dikshit, M.B.; R. K. Goyal, M.B.; and Basudeva Narayana, M.B.

M.B., Ch.B.—F. S. Airey, A. K. Arif, *R. W. Armour, S. O. Awoliyi, D. A. Baird, P. B. Barker, William Barnetson, P. G. [illegible] W. R. [illegible] Brown, [illegible] Burgin, [illegible] mpbell, [illegible] R. W. [illegible] ckburn, [illegible] J. Cooper, A. F. Cowan, W. J. A. [illegible] Davies, H. W. Dryerre, J. R. Durham, [illegible] S. L. Forrest, H. F. Galler, Ann [illegible] Gibb, David Gilmour, J. C. Goligher, H. M. Grant, J. S. Gra [illegible] N. A. Gray, Norman Gray, R. D. Gray, Arnold Greenbl [illegible] Gunvald C. Gundersen, M. I. Hall, Alison M. B. Hamilt [illegible] John Hart-Mercer, W. K. Henderson, H. B. T. Holland, Isab [illegible] Hood, James Hutton, Augusta S. Inglis, *A. J. Innes, J. R. B. Johnstone, Josephine J. M. Kamm, J. S. Kaufman, J. M. Kerr, T. A. Kester, J. H. Kretzmar, G. K. Lloyd, N. M. L. Lund, John Macaskill, I. R. I. MacDonald, W. T. Macdonald, J. A. B. M'Dougle, G. B. MacGibbon, J. H. M'Intyre, W. R. H. Mackay, I. K. MacKenzie, C. R. M'Laughlin, Neil Maclean, I. P. J. MacNaughtan, John Magill, J. A. Malloch, William Maxwell,

. Miller, N. C. F. Milne, E. K. Morris, *K. M. Morris, T. M. lock, G. M. Naicker, E. E. Nathaniel, C. C. Nicholson, ge Nisbet, E. F. Northcroft, G. J. Partington. M. K. Pillai, . Reeve, S. C. C. Remedios, *A. J. Rhodes, S. G. Roberts, es Ronald, Samuel Rosner, A. I. Ross, J. A. Ross, G. D. ley, A. H. Saleh, James Sandilands, Jane A. M. Shepherd, . Smith, Maud I. Smith, Thomas Sommerville, J. M. M. Steven, t P. Stewart, *J. K. Sutherland, Muriel A. W. Swanston, . Taylor, Mary W. Taylor, J. F. Thomson, R. N. Traquair, G. Waddell, Patricia S. Warren, E. S. Watson, A. J. Webster, O. Westwater, H. I. Whitelocke, Molly B. Wilson, R. H. nfield, I. U. Young, John Young, and Katharine M. Young.

* Passed with honours.

.P.M.—M. U. Ahmad, William Aitchison, Adam Armit, W. M. de Silva, Israel Gordon, Ellen M. Hegarty, Aileen E. thers, and Robert Woodrow.

D.T.H. & H.—Harry Bayliss-Stokes, V. E. M. Lee, A. W. se, G. J. Smit, and George Watt.

Diploma in Psychiatry.—Laura M. D. Mill.

Diploma in Radiology.—F. M. Gordon and A. R. Sahy.

The following awards of prizes were made:—

Cameron prize in therapeutics to Sir E. Sharpey-Schafer, .R.S., in recognition of the advances arising out of his discoveries endocrinology; Ettles scholarship and Leslie gold medal to . W. Armour, M.B.; Scottish Association for Medical Educa-on of Women prize, Molly B. Wilson, M.B.; Stark scholarship n clinical medicine, D. L. C. Bingham, M.B.; Mouat scholarship n the practice of physic, J. M. M. Steven, M.B.; Buchanan cholarship in midwifery and gynæcology, K. M. Morris, M.B.; ames Scott scholarship in midwifery and gynæcology, A. J. Rhodes, M.B.; Beaney prize in anatomy and surgery, R. W. Armour, M.B.; Annandale gold medal in clinical surgery, B.; Royal Victoria Hospital tuberculosis L. C. Bingham, M.B.; Murdoch Brown medicine, K. M. Morris, M.B.; Dorothy ize, Molly B. Wilson, M.B.; Pattison rize in clinical surgery, R. H. Winfield, M.B.; M'Cosh bursary, . M. Parker, M.B.; Gunning Victoria Jubilee prize in surgery, . J. Kellar, M.B.; Gunning Victoria Jubilee prize in pathology, . E. van Rooyen, M.D.; Gunning Victoria Jubilee prize in zoology, Hector Maclean, B.Sc.; Milner Fothergill medal in therapeutics, D. M. Dunlop, M.D.; Thomson memorial medal in child life and health, H. T. H. Arnott, M.B.; and Wightman prize in clinical medicine, J. du T. le Roux, B.Sc.

In an address to the new graduates Prof. A. J. Clark, F.R.S., the promotor, said it was demonstrably untrue that the medical profession destroyed its own livelihood when it advanced knowledge about the prevention and cure of disease. While the death-rate was steadily falling the importance and prestige of the medical profession was as steadily rising. To-day the prevention of disease or its cure at an early stage was becoming the chief function of the doctor, and this was making the practice of medicine both more difficult and more interesting. Medical practice of the future would, he thought, be largely concerned with conditions intermediate between the fields now covered by the sciences of physiology and pathology.

Royal College of Physicians of Edinburgh

At a meeting of the college on July 17th, with Dr. Edwin Bramwell, the president, in the chair, Dr. David Rhys Lewis (Swansea) was introduced and took his seat as a fellow. Dr. John Ronald Currie (Glasgow) and Dr. Alistair Graham Cruikshank (Edinburgh) were elected to the fellowship.

International Association for the Prevention of Blindness

Prof. de Lapersonne presided at a meeting of the executive committee of this association held in Paris, when the activities of the association included the appointment of a commission to discuss the classification of the causes of blindness; among the members are Prof. van Duyse (Belgium), Dr. Mazini Bey (Egypt), Prof. de Lapersonne (France), Mr. Bishop Harman (England), Dr. Marx (Netherlands), Prof. Marquez (Spain), and Dr. Park Lewis (U.S.A.). On behalf of the American Ophthalmological Society and other bodies the Dana medal was presented to Prof. de Lapersonne for his distinguished services in ophthalmology and prevention of blindness. Then followed a meeting of the general assembly in conjunction with the International Organisation for the Struggle against Trachoma. Prof. E. de Grosz (Budapest) spoke, and reports were received of trachoma all over the world from British Colonies (MacCallan), Egypt (Mazini Bey and Tewfik), U.S.A. (McMullen and Rice), Southern Italy (Maggiore), Algeria (Lasmet), Indo-China (Hermant), India (Wright), Greece (Trantas), Dutch Netherlands (Wibaut), and Tunis (Cuenod). The date and seat of the assembly for 1935 were left to be decided later.

Hospital Saturday Fund

The Hospital Saturday Fund collection which takes place on Sept. 22nd will, it is announced, receive an anonymous gift of £1000.

Gordon Hospital, Vauxhall Bridge-road

Hitherto this hospital has never been in debt and has never appealed. Rebuilding and enlargement have now become urgent and it is desired to celebrate the jubilee of the institution by raising £100,000 for the purpose. Sir John Dewar has started the fund with a donation of £10,500.

Carnarvonshire and Anglesey Infirmary

The Princess Royal recently opened a new wing of this hospital which has been erected as a memorial of the late Mrs. Parry Jones, of Cleveland, U.S.A., whose husband has given £12,000 towards the cost. On the same occasion the Princess opened a new light therapy department given by Sir Michael Duff-Assheton-Smith.

Enlarging Shenley Mental Hospital

The county council is already preparing for the enlargement of its new mental hospital at Shenley in Hertfordshire, which was recently opened by the King. Tenders are being obtained for the erection of a second section at a cost of £377,000.

Extension of Kettering Hospital

Lord Henley, chairman of the Northamptonshire public health committee, recently formally opened enlargements of this hospital which have cost £13,000. Two medical wards of bungalow form have been added, with a whole operating theatre block and enlarged accommodation for nurses.

Wigan Infirmary

Last year the Royal Albert Edward Infirmary, Wigan, treated 3669 patients to a conclusion and there were 13,719 new out-patients. The average cost per head was £120 12*s.* 9*d.*, an increase of 9*s.* 8¼*d.* Out-patients cost 9*s.* 4*d.* each, an increase of 4¾*d.* per head.

West Kent General Hospital

The report for 1933 shows that, thanks to the increase from 1*d.* to 2*d.* per week in the contributions to the pay day fund, the ordinary income increased by about £1700. New in-patients numbered 1670, whose daily cost was 8*s.* 7¾*d.*, a fall of 4½*d.* Their average stay was 19·8 days.

Preston Maternity Hospital

A maternity hospital is to be added to Preston Royal Infirmary, and operations have already been begun. It will be an entirely separate hospital of between 40 and 50 beds, and is estimated to cost £30,000 with an additional £10,000 for nurses' accommodation. There will be two general wards, each of twelve beds, six single-bed wards, an antenatal ward of six beds, and a separate isolation block, in addition to two maternity theatres and a small operating theatre.

Prince of Wales's General Hospital, Tottenham

The provision of better nurses' homes has become so urgent that an appeal is being made for £20,000 that one wing may be begun immediately. The nurses' quarters are officially stated to be "in very bad condition and quite unsuitable." Eventually accommodation will have to be provided for 200 nurses. When the first £2000 has been collected King Edward's Fund will double it, and Sir Alfred Barratt has promised £500 if four other persons will give a similar amount.

Hull Royal Infirmary

Last year the deficit of ordinary income over ordinary expenditure was nearly £7000. There have, indeed, been annual deficits since 1928; and the accumulated debt now verges upon £24,000, and the report says that "the infirmary cannot much longer continue to fulfil its full service under these conditions." There were 5544 in-patients, an increase of 141, but at 15,647 there was a fall of 1400 in the number of out-patients. Patients stayed an average of 21·32 days; their average total cost was £7 18*s.* 3¼*d.*, and the weekly cost £2 11*s.* 11¾*d.*

Public Support of Hospitals

A boxing tournament organised by Sir Harry Preston at Brighton in aid of the hospitals and kindred institutions—one of a number during the past 20 years or so—resulted in a sum of £2000 being allocated to eleven institutions. Sir Harry suggests that with a view to impressing the public with the value of the work, every man and woman should be compelled by law to pay a visit to a large hospital once a year.

Hove Home for Blind Women

On July 20th Lord Leconfield opened a new home for blind women at Hove. Known as Wavertree House, it has been purchased and equipped by the National Institute for the Blind. Accommodation is provided for 25 people who have been removed thither from their quarters in Queen's-road, Brighton, and at the home at Clifton, Bristol. The Brighton home is the one where Dr. Moore, the inventor of the Moon alphabet, resided, and it is still being carried on as a centre for the printing of Moon literature, the only one of its kind in the world.

Glasgow Hospital for Sick Children

A fund of £50,000 is being raised for the provision of an orthopædic department, and at the end of last year, the date of the report, £35,000 of the amount had been given. The new buildings will include cots for paying patients. In 1933 there were 5878 new in-patients, 668 of whom were infants under 12 months. The average duration of residence at all ages was 15·5 days, and the daily cost of each patient was 7*s.* 1*d.* The cost of each occupied cot for the year was £129 7*s.* 2*d.* At the end of the year there was a credit balance of £795, attained only by using legacies and special donations. In the preceding year the surplus was £4253.

Congress on Alcoholism

The twentieth International Congress on Alcoholism will be held at the Imperial Institute, South Kensington, London, S.W., from July 30th to August 3rd, when the subjects for discussion will include national surveys of the alcohol problem from educational, economic, medical, legislative, and other points of view; alcohol in relation to motoring and sport; alcohol in relation to heredity and environment; the causes and treatment of inebriety; and the international coördination of temperance work and effort. Addresses will be delivered by Sir William Willcox on the toxicological aspects of alcohol and drug addiction, and Sir George Newman on the teaching of hygiene in schools. Receptions will be given by the president, Lord Rowallan, and others. Membership tickets may be had from the Secretariat, Room H, Imperial Institute.

Donations and Bequests

In addition to other contingent bequests, the late Charles H. Baxter, of Winchelsea, left, on the death of all his brothers and sisters, £1000 to the Royal Waterloo Hospital for Children and Women, £500 to the Royal East Sussex Hospital, Hastings, and the same amount of money to the Central London Ophthalmic Hospital.—The late Miss Laura J. Crabb, of Tunbridge Wells, left, among other bequests, £1000 upon trust for the upkeep of the churchyard of the Parish Church of Great Baddow, Essex, or, failing this, to the Chelmsford and Essex Hospital and Dispensary; £5000 to the Church Missionary Society for Africa and the East, for medical work; £20,000 to the Church of England Zenana Missionary Society; £1000 to the Tunbridge Wells General Hospital; £1000 to the Chelmsford and Essex Hospital and Dispensary; £250 to the Eye and Ear Hospital, Tunbridge Wells; and £250 to the Convalescent Home for Children, Hawkenbury, Tunbridge Wells.—The late Mr. Charles Henry Garton, of Banstead, among other bequests, left £5000 to the Royal South Hants Hospital; £2000 to the Bolingbroke Hospital; £2000 to the London Hospital; £2000 to the Westminster Hospital; £2000 to the Epsom and Ewell Cottage Hospital; £1000 to the Moorfields Eye Hospital; and £500 to the Free Eye Hospital, Southampton.—By the will of the late Mr. John Braund, of Exmouth, the Exmouth Cottage Hospital will benefit by £2000. The late Mrs. Jane Elizabeth Oliver, of Bowdon, Cheshire, left among other bequests £1000 to Ancoats Hospital, for general purposes, and a further £1500 for the endowment of a bed, to be known as "High Croft Bed."

A Stretcher for Railway Journeys

A Great Western Railway carriage cleaner at Ta has designed a new type of stretcher suitable for railways. The ordinary standard stretcher is too wi pass through carriage doors so that invalids have to be into and from the compartment, or conveyed in the guard van. The new stretcher, which is slightly narrower, fitted with a removable "shock-absorber" bed, and an attachment for holding an adjustable bedrest handles that slide in flush with the ends. It can be quickly fixed to or removed from any standard stret fitted in ambulances or those used in hospitals, an cross-rail at each end serves as an extra means of carr short distances and in confined spaces or negotia passage corners. The "Parratt" stretcher, as it named after the designer, has been patented on his beh by the G.W.R., and will be available at its princi stations, and also, on demand, at any station for journey.

Rickets at Manchester

The report of the Manchester Babies' Hospital for the year ended on March 31st last shows the usual diminuti in the number of cases of true rickets sent for admissi The percentage fell from 21·42 in 1924 to 4·99 in 193 This is thought, however, not to be an exact picture the diminution of rickets in the city, since rickets is st prevalent during certain periods of the year amo children not attending welfare centres and in charge o indifferent mothers. There is a decrease where the childre are under medical observation. There were 517 admission and the average stay was 51·59 days. A new nurses' home to house 30 nurses is to be built at a cost of £10,000. Moreover, it is felt that the hospital can no longer remain efficient without an operating theatre. The X ray department is too small for modern apparatus, the massage and sunlight departments are insufficient to cope satisfactorily with the increased work, and the great number of biochemical, bacteriological, and pathological tests necessitates a larger laboratory.

Royal Manchester Children's Hospital.

A grant of £20,000 has been made to this hospital by the trustees of the late Mr. Zachary Merton for the building of a new convalescent home. It will be erected beside the hospital, and an appeal will shortly be issued for £100,000 to endow the 40 beds.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 14TH, 1934

Notifications.—The following cases of infectio disease were notified during the week: Small-pox, (last week 1); scarlet fever, 2343; diphtheria, 1152 enteric fever, 27; acute pneumonia (primary or influenzal), 579; puerperal fever, 38; puerperal pyrexia, 100; cerebro-spinal fever, 23; acute poliomyelitis, 9; acute polio-encephalitis, 2; encephaliti lethargica, 9; continued fever, 1 (Cambridge) dysentery, 14; ophthalmia neonatorum, 86. No cas of cholera, plague, or typhus fever was notified durin the week.

The number of cases in the Infectious Hospitals of the Londo County Council on July 23rd-24th was as follows: Small-po 0; scarlet fever, 1667; diphtheria 1529; measles 894 (las week 1061); whooping-cough 296; puerperal fever, 24 mothe (plus 5 babies); encephalitis lethargica, 269; poliomyelitis, 2 "other diseases," 231. At St. Margaret's Hospital there we 16 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including Londo there was no death from small-pox, 1 (1) from enter fever, 16 (4) from measles, 5 (1) from scarlet feve 13 (1) from whooping cough, 39 (8) from diphtheri 39 (13) from diarrhœa and enteritis under two year and 9 (0) from influenza. The figures in parenthes are those for London itself.

Of the deaths from measles 3 were reported from She 2 from Stoke-on-Trent. Whooping-cough was fatal in t cases at Liverpool. Diphtheria caused 3 each at Portsmout Kingston-upon-Hull and Birmingham. Four fatal cases diarrhœa were reported from Birmingham, 3 from Liverpool, from South Shields.

The number of stillbirths notified during the wee was 249 (corresponding to a rate of 39 per 1000 tot births), including 42 in London.

Medical Diary

nformation to be included in this column should reach us proper form on Tuesday, and cannot appear if it reaches later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

LLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, July 30th to SATURDAY, August 4th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square. Tues., at 2.30 P.M., lecture-demonstration (illustrated by cases) on Sciatic Pain, by Dr. A. E. Clark-Kennedy.—PANEL OF TEACHERS. Individual clinics in various branches of medicine and surgery available daily.—Courses, demonstrations, &c., arranged by the Fellowship of Medicine are open only to Members and Associates.

Appointments

MILLER, A., F.R.C.S. Edin., has been appointed Hon. Surgeon in charge of the Ear, Nose, and Throat Department, French Hospital.

Certifying Surgeons under the Factory and Workshop Acts: EDGAR, W., M.B., Ch.B. Glasg. (New Cumnock, Ayrshire); VINCENT, E. W., M.B., Ch.B. Leeds (Filey, Yorks.).

Vacancies

For further information refer to the advertisement columns

Accrington, Victoria Hospital.—H.S. £150.

Ashton-under-Lyne District Infirmary.—H.S. At rate of £150.

Barnsley, Beckett Hospital and Dispensary.—H.P. £200.

Bath and Wessex Children's Orthopædic Hospital, Combe Park.—Res. Asst. Surgeon. £350.

Birmingham, Monyhull Colony Certified Institution.—Jun. Asst. M.O. £350.

Bolton Royal Infirmary.—Res. Surg. O. £250. Also Asst. Res. Surg. O. £200.

Bootle General Hospital.—H.P., 2 H.S's., and Cas.O. Each at rate of £150.

Bradford Royal Infirmary.—H.P. and Two H.S.'s. Each at rate of £135.

Brighton, New Sussex Hospital for Women and Children.—H.S. £100.

Cancer Hospital, Fulham-road, S.W.—Clin. Asst. £250.

Cardiff Royal Infirmary.—Hon. Physician.

Central London Ophthalmic Hospital, Judd-street, W.C.—Chemical Pathologist. £105.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Hon. Assts. in Out-patient Dept.

Charing Cross Hospital, W.C.—H.P. to Radiological Dept. At rate of £50.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.

Colchester, Essex County Hospital.—H.P. £150.

Connaught Hospital, Walthamstow, E.—Res. M.O. At rate of £150.

East Lancashire Tuberculosis Colony, Great Barrow.—H.P. At rate of £100.

Edinburgh Royal Infirmary.—Radiologist. £1500.

Exeter, Royal Devon and Exeter Hospital.—Hon. Asst. Surgeon. Also H.S. to Ear, Nose, and Throat Dept. At rate of £150.

Evelina Hospital for Sick Children, Southwark, S.E.—H.S. At rate of £120.

Gloucester, Gloucestershire Royal Infirmary, &c.—Hon. Ear, Nose, and Throat Surgeon.

Great Yarmouth General Hospital.—H.S. £140.

Grimsby County Borough.—M.O.H. £1000.

Guildford, Royal Surrey County Hospital.—H.S. £150.

Leeds Maternity Hospital, Hyde-terrace.—Second H.S. At rate of £50.

Liverpool, David Lewis Northern Hospital.—Cas. O. At rate of £120. Four H.S.'s, Two H.P.'s. Each at rate of £80. Also H.S. to Gynæcological and Ear, Nose, and Throat. At rate of £80.

Liverpool Heart Hospital, Oxford-street.—Research Fellowships.

iverpool, Royal Southern Hospital.—Two H.P.'s, Three H.S.'s. M.O. to Special Depts., and Res. Anæsthetist. Each at rate of £60. Also Res. Cas. O. At rate of £100.

anelly and District Hospital.—H.S. £150.

London Jewish Hospital, Stepney Green, E.—Cas. O. At rate of £150.

London University.—University Chair of Medicine. £2000. University Chair of Pathology. £1200. University Readerships. Each £800.

Manchester, Ancoats Hospital.—H.P., and H.S. Each at rate of £100. Surg. Reg. and Orthopædic Reg. Each £50. Also Hon. Gynæcologist.

Manchester, Booth Hall Hospital.—Asst. M.O.'s. Each £200.

Manchester Centre, National Radium Commission Scheme.—Asst. Radium Reg. £400–£500.

Manchester, Monsall Hospital for Infectious Diseases.—Jun. Res. Asst. M.O. At rate of £250.

Manchester, Royal Eye Hospital.—Jun. H.S. £120.

Middleton-in-Wharfedale Sanatorium, near Ilkley.—Res. M.O. £250.

Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Jun. Res. M.O. At rate of £100.

Near Pontefract, Ackworth School.—Part-time M.O.

Newcastle General Hospital.—Two H.S.'s and H.P. Each at rate of £150.

Norwich, Jenny Lind Hospital for Children.—Jun. Res. M.O. £100.

Norwich, Norfolk and Norwich Hospital.—H.S. to Spec. Depts. £120.

Oswestry, Robert Jones and Agnes Hunt Orthopædic Hospital.—Two H.S.'s. Each at rate of £200.

Queen Mary's Hospital for the East End, E.—Asst. Pathologist. £400. Anæsthetist. Locum Tenens. 4 gns. a week.

Queen's Hospital for Children, Hackney-road, E.—H.S. and Cas. O. Each at rate of £100.

Royal Eye Hospital, St. George's-circus, Southwark, S.E.—Hon. Asst. Surgeon.

Royal London Ophthalmic Hospital, City-road, E.C.—Refraction Asst. £100.

Royal Naval Medical Service.—Ten M.O.'s.

Salisbury General Infirmary.—H.P. At rate of £125.

Sheffield Children's Hospital.—H.S. and H.P. Each at rate of £100. Also Res. M.O. £175.

Sheffield, Jessop Hospital for Women.—Asst. Reg. and Obstet. Tutor. £400. Also H.S. At rate of £100.

Sheffield Royal Hospital.—Res. Surg. O. £200.

Shrewsbury, Royal Salop Infirmary.—Cas. O. and Res. Anæsthetist. At rate of £160.

South-Eastern Hospital for Children.—Jun. Res. M.O. At rate of £100.

St. Mary's Hospital for Women and Children, Plaistow, E.—Hon. Ophth. Surgeon.

Sutton and Cheam Hospital.—Hon. Radiologist.

Swansea General and Eye Hospital.—H.P. At rate of £150.

Tunbridge Wells, New Kent and Sussex Hospital.—Sen. and Jun. H.S. £175 and £125 respectively.

Torquay, Torbay Hospital.—H.P. and H.S. Each £175.

Warrington County Mental Hospital, Winwick.—Deputy Med. Supt. £750.

Weir Hospital, Grove-road, Balham, S.W.—Jun. Res. M.O. £150.

Wolverhampton Royal Hospital.—H.S. for Orthopædic and Fracture Dept. At rate of £100.

Worcestershire Mental Hospital, Barnsley Hall, Bromsgrove.—Second Asst. M.O. £350.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at East Grinstead, Sussex.

Births, Marriages, and Deaths

BIRTHS

HARWARD.—On July 20th, at Odiham, the wife of Dr. R. L. Harward, of a daughter.

JONES.—On July 21st, at Welbeck-street, W., the wife of Arthur Rocyn Jones, F.R.C.S., of a daughter.

MILLER.—On July 21st, at Welbeck-street, W., the wife of Dr. Emanuel Miller, of a son.

ROBINSON.—On July 19th, the wife of Geoffrey Lawrence Robinson, M.B., of a daughter.

MARRIAGES

LYLE—HUGHES.—On July 21st, at Westerham Parish Church, Kent, Eric H. Willoughby Lyle, M.A., M.B., B.Ch., D.O.M.S., to Elizabeth E. Hughes, younger daughter of the late F. R. Hughes and of Mrs. Hughes, formerly of Hale, Cheshire.

DEATHS

CROSS.—On July 14th, at his residence, Clay Point, Flushing, Falmouth, Cornwall, William Foster Cross, M.R.C.S. Eng., L.R.C.P. Lond., consulting anæsthetist to St. Bartholomew's Hospital, London, aged 61.

MACKENZIE.—On July 19th, at Sedgford House, Underdale-road, Shrewsbury, Allan Grant Mackenzie, M.D., M.R.C.P., F.R.C.S., aged 79.

MAYOU.—On July 20th, at Portland-court, Marmaduke Stephen Mayou, F.R.C.S., of Harley-street, and Alison House, Camberley, aged 58.

ROUSE.—On July 17th, at Thalassa, Farncombe-road, Worthing, Algernon Edward Rouse, M.R.C.S., L.R.C.P., in his 62nd year.

WARING.—On July 21st, at Birmingham, after a short illness, Charles John Waring, M.R.C.S., L.R.C.P.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

A STUDY OF THE UNSTABLE BOY

BEING AN INVESTIGATION OF 120 CONSECUTIVE CASES AND AFTER-HISTORIES

BY MURIEL BARTON HALL, M.D.
HONORARY PHYSICIAN TO THE LIVERPOOL PSYCHIATRIC CLINIC

DURING a review of 1300 consecutive cases of early mental, nervous, and behaviour disorders seen at the Liverpool Psychiatric Clinic during the past ten years it was found that 407 were patients in the second decade, 120 of these being male and the remainder female. The discovery that 31 per cent. of the cases were adolescent when first seen at the clinic suggested that an analysis of the case sheets and a comparison with the subsequent histories of these cases might reveal information of interest from the points of view of ætiology, diagnosis, and prognosis.

The following details are those of 120 unselected male adolescents who were between the ages of 10 and 19 years inclusive when first seen at the clinic, and with whom, with the exception of three cases, it has been possible to get into touch either directly or through a psychiatric social worker, within the past three months.

Findings

Of the 120 cases, 62 were referred to the clinic by doctors, 33 by social agencies, 21 by public authorities, and 4 from other sources. Seventy-five were referred because of nervous symptoms, 45 because of a behaviour disorder. After investigation the cases were divisible into five main groups according to their most prominent feature, as follows :—

Psychoneurosis	51
Behaviour disorder	25
Intellectual deficiency	24
Physical disorder	14
Psychosis	6

For the purpose of this paper, the term behaviour disorder signifies a condition of abnormal behaviour from the causation of which mental, nervous, physical, or intellectual factors could be excluded.

The factor of general intelligence was investigated in detail. Classification of the cases according to five grades of intellectual development resulted in Table I. :—

TABLE I.—*Classification according to Intelligence Quotient*

Intelligence.	I.Q.	Cases.
Very superior	Over 130	0
Superior	110–129	12
Average	90–109	47
Inferior	70–89	36
Very inferior	Under 70	25

In Table II. these findings are reviewed in relation to the diagnosis.

TABLE II.—*Intelligence and Type of Disorder*

—	Psycho-neurosis.	Behaviour disorder.	Intellectual deficiency.	Physical disorder.	Psychosis.
Superior ..	9	1	—	1	1
Average ..	31	5	—	8	3
Inferior ..	11	19	—	5	1
Very inferior ..	0	0	24	0	1
Totals ..	51	25	24	14	6

The factors of heredity and environment were onsidered, and their significance in relation to the ases under investigation is seen in Table III.

Of the commoner factors in the heredity, psychoneurosis occurred 26 times, immorality 12 times, alcoholism, insanity, mental deficiency, and epilepsy each 10 times, tuberculosis and violent temper each 8 times. Suicide was twice revealed in the family histories. Two of the patients were known to be illegitimate.

TABLE III.—*Heredity, Environment, and Type of Disorder*

—	Abnormal heredity.		Family group.	
	Absent.	Present.	Normal.	Abnormal.
Psychoneurosis ..	19	32	37	14
Behaviour disorder ..	4	21	9	16
Intellectual deficiency	10	14	16	8
Physical disorder ..	12	2	12	2
Psychosis	1	5	3	3
Totals	46	74	77	43

Environmental factors are always difficult to assess, but in this investigation attention was paid to any factor which appeared to have disturbed the normal relationship of the family group during the patient's childhood. Loss of one parent had occurred in 22 cases—by death 13 times, by desertion 5 times, by separation twice and by divorce twice. In 21 cases there were substitute parents—namely, 7 step-parents, 6 relatives, 1 foster parent, while 7 cases had been brought up in orphanages.

Treatment and After-history

Fifty-four cases were considered as suitable for treatment by psychological methods of approach, but this was actually undertaken in only 36 cases, the remaining 18, owing to distance or hours of employment, being unable to attend the clinic with sufficient regularity. The other 66 cases were considered unsuitable for treatment at the clinic. In each of them, however, recommendations were made to the doctor, the social worker, or the public authority official concerned with the patient's future handling either in his own home or, where necessary, in some other environment.

The relative suitability of cases for treatment is shown in Table IV.

TABLE IV.—*Diagnosis and Suitability for Treatment*

—	Suitable.	Unsuitable.
Psychoneurosis	45	6
Behaviour disorder	4	21
Intellectual deficiency ..	2	22
Physical disorder	0	14
Psychosis	3	3
Totals	54	66

The number of cases in the present series is too small to warrant any statement as regards the result of psychological treatment. The two cases of intellectual deficiency that were considered suitable for treatment were also suffering from a psychoneurosis.

In each case an effort was made to obtain an after-history concerning the patient's progress as regards symptoms and employment since his last attendance at the clinic. In 3 cases this was impossible because the family could not be traced. In 24 the after-history was less than 12 months in duration, a period which is considered not long enough to warrant inclusion in the series. In the remaining 93 cases the after-histories obtained cover periods varying from one to nine years in duration as follows :—

Years	.. 9	.. 8	.. 7	.. 6	.. 5	.. 4	.. 3	.. 2	.. 1
Cases	.. 6	.. 8	.. 7	.. 9	.. 4	.. 12	.. 11	.. 12	.. 21

ADDRESSES AND ORIGINAL ARTICLES

SOME OBSERVATIONS ON INDUSTRIAL DERMATITIS*

By SIBYL G. HORNER, M.B. Lond., D.P.H.
H.M. MEDICAL INSPECTOR OF FACTORIES

DERMATITIS of occupation has a wider interpretation than is usually conceded to the condition called eczema. It includes under the heading of "dermatitis" almost any pathological condition of the skin and its appendages which can be attributed to occupation.

It may be well to deal shortly with the official position of occupational dermatitis. It is not, as is sometimes supposed, notifiable under the Factory and Workshop Act; the only skin conditions which are so dignified are anthrax, "epitheliomatous ulceration," and chrome ulceration. The onus of notification of these is on the practitioner if he believes the condition to have been contracted in a factory or workshop, and also on the occupier of the factory or workshop even though the subject remains at work. The notifiable conditions, as well as "dermatitis due to dust or liquids," are, however, compensatable under the Workmen's Compensation Act. The decision as to whether the condition comes within this description lies with the certifying surgeon, of which there are a number throughout the country. Appeal lies to the medical referee, whose decision as regards the disease is final.

There are two main reasons for the importance of dermatitis of occupation: (1) the fact that one attack of dermatitis in industry is more than likely to be followed by another under the same conditions; (2) the other the enormous cost of the bill of compensation.

In 1932 there were nearly 2000 compensated cases of "dermatitis due to dust or liquids"—the highest figure yet reached. Dermatologists will appreciate the length of disablement which is likely to result among these unfortunate 2000, and will also recognise the lessened security of these workers on their return to their occupation. This is sheer wastage of health and money, for the astonishing fact is that dermatitis of occupation is largely preventable.

We have come to know more about the condition from cases of dermatitis voluntarily reported by employers in industry. About half the compensated cases are subjected to investigation in this way. We know, for example, that more cases of dermatitis are caused by what may be classed as "cleansers" used after work than by irritants directly encountered at work.

One of these cleansers met with recently proved to be largely white spirit with more than a dash of cresylic acid. Notable among these harmful cleansers is paraffin. The *Times* has recently been the medium for some correspondence headed "Paraffin for the bath"! The effects of such treatment, either on the hands of the domestic cleaner or on the more delicate parts of the epidermis of the bather, from any residual paraffin, are evidently not generally appreciated, for no mention was made of them. The ignorance of workers is not, in the circumstances, a matter for wonder.

Some years ago workers were content to leave the signs of toil on their skin until a week-end cleaning, but the modern worker, man and woman, is not so satisfied. Outside the factory manual workers are often indistinguishable from their brethren who handle the pen. It is not necessarily the dirty workers, except those in contact with oil, who acquire dermatitis, but often those with a passion for cleanliness. One man was aggrieved because he was so affected although he washed "twenty-four times daily at the works." It is, of course, praiseworthy and desirable that workers should leave the factory clean, but further education of those responsible is necessary to ensure that the process of cleaning does not produce dermatitis.

The worst offenders amongst cleansers are alkalis (washing soda, soda ash, and chloride of lime, which are popular—the latter two for their bleaching effect), and various degreasing agents, such as paraffin, turpentine, and methylated spirit.

Preventive Measures before Work

But this is, perhaps, beginning at the end. What preventive measures can be taken before work? Gloves are the first for consideration, but unless there is unavoidable contact with powerful irritants such as the strong acids—e.g., sulphuric, nitric, chromic, hydrofluoric; solutions of bichromates of sodium and potassium, and caustic soda, and so forth—gloves are best avoided, although they are valuable against trauma from heat and other physical causes. The best and most widely applicable protection is, in my opinion, afforded by the use of some emollient before work. This can be non-greasy, greasy, or waterproof as the work demands, and not only is a certain degree of protection ensured at work but the final cosmetic wash will not be a further exposure to risk, for it is found that paint, dyes, french polish—to name only a few—will then be capable of removal by gentler methods.

Causative Agents and Occupations

Tables I. and II. show respectively the chief causative agents and the occupations of those affected

* An address delivered before the St. John's Dermatological Society on April 25th, 1934.

in the cases of dermatitis in industry which have been voluntarily reported in the years 1927–1932 inclusive.

SUGARS, OIL, AND TERPENES

Of the causative agents *alkalis* have already been discussed; they are very often cleansers. *Sugar* is the chief cause of dermatitis in the manufacture of sugar confectionery, sugar refining, and biscuit making (the processes of "creaming and icing"). There always seems to be an element of infection in sugar dermatitis; one meets with sugar "boils" in sugar refiners, subacute and acute perionychia in sweet-makers. Indeed, among those engaged in candying fruits one is certain to find instances of sepsis around the nails. Sugar may afford a suitable pabulum for organisms either present on the skin or more usually infecting abrasions, possibly themselves caused by trauma and friction of sugary surfaces. There is evidence that the injuries caused by unskilled manicure hasten the development of perionychial infections among sugar workers. The work of MacLeod [1] on the rôle that monilia infection plays in the causation of suppurative perionychia characterised by a pad or bolster-like swelling of the nail wall on workers exposed to sugar, is of striking interest. It may be that the monilias and other yeast-like fungi will provide the key to some unsolved problems of causation in industrial dermatoses.

The *bichromates*, but not the chromates of potassium and sodium, and *chromic acid* cause either a dermatitis or localised ulceration, depending mainly on the presence or not of trauma. Fair-haired people are particularly prone to a "chrome dermatitis," and their presence at a chromium plating or anodic oxidation bath (where aluminium for aircraft is treated against corrosion by sea-water) calls for peculiar care.

It has been found that *mineral oil* is slightly bacteriocidal towards the *Staphylococcus aureus*, the organism frequently associated with oil folliculitis. There is not, therefore, much reason for the fear that oil folliculitis will be disseminated in an engineering shop through the medium of the oil; the medium of infection is more likely to be the common towel. The generally accepted belief is, however, that the infection is autogenous and that the oil both acts as a vehicle and also over-lubricates the skin, causing increased activity of sebaceous glands, the two together resulting in a septic folliculitis. Some success has been achieved in the prevention of this type of dermatitis by the use, after work, of an antiseptic alkaline wash (Dakin's solution B.P.C.) which removes the oil more thoroughly from the skin than can be effected by ordinary methods. It is reasonable to assume that corresponding protection would be afforded if the workers could be prevailed upon to perform a surgical "wash up" before work.

Turpentine dermatitis is now of more than usual interest because the irritating properties of some everyday substances—such as oranges, lemons,[2] and celery [3]—have only recently been recognised as due to the same substance—i.e., limonene—which is itself a terpene. So nearly are lemon oil and turpentine related that the latter was at one time a common adulterant for lemon oil.[1] Orange oil and lemon oil consist of over 90 per cent. dextro limonene. Moreover, pinene, which is believed to be responsible for the irritant qualities of some turpentines, is not only very closely related to limonene but is itself present in lemon oil. There are four grades of turpentine:—

1. Gum spirits of turpentine, made from gum (oleoresin) from the living tree.
2. Steam distilled wood turpentine—i.e., steam distilled from oleoresin within or extracted from the wood.
3. Destructively distilled wood turpentine—the product of distillation of the wood and roots of tree.
4. Wood turpentine; this grade includes the product of (2) and (3).

The lower grades—i.e., (3) and (4)—are believed to be more productive of dermatitis.

Evidence has been produced to prove that steam distilled turpentines contain some ingredient susceptible of removal by fractional distillation, probably a saturated hydrocarbon in small amounts with a boiling-point somewhere between that of *a* pinene and dipentene, which is decidedly more irritating than the other constituents.

Of turpentine substitutes there are a number. The chief are rosin spirit (iodine value 90–180), shale spirit (60 per cent. paraffins and oleofines), petroleum spirit, coal-tar naphtha, and tetralin (tetrahydronaphthalene).

Although dyes figure monotonously in the list of causes, this classification probably includes some cases where cleansers are really at fault, for accurate information as to methods of removal of dyes from the skin is difficult to obtain. Paraphenylene diamine, although the cause of most cases of fur dermatitis [4] outside industry, and of "ursol dermatitis" which followed the wearing of badly dyed leather shoes during the war, does not figure largely in the cause list of industrial dermatitis.

BREAD, WOODS, AND BULBS

All the ingredients of *bread*—flour, improvers, salt, yeast—have been suspect as the cause of dermatitis.

In Australia work has been done on bakers' dermatitis within the last few years, and the conclusions reached were that flour improvers, chiefly ammonium persulphate, were to blame.[5] One man in twenty—fifty in all—were affected in dough making. The rash—vesicular papulo-erythematous in character—was present on the limbs and face. Cutaneous tests revealed sensitivity to ammonium persulphate, and removal of this activator practically abolished the incidence of the disease.

It is worth recording that the amount of ammonium persulphate used in England for the treatment of flour is less than that used in other countries. In England 6 g. and in other countries 10 g. is a usual amount of ammonium persulphate in 100 kg. of flour. A test for the presence of ammonium persulphate in flour may be made by spreading it smoothly with a spatula. A drop of neutral 15 per cent. KI solution will then show a positive result by brown stippling. An examination in this country of workers in the production of ammonium persulphate *did not reveal instances of conditions resembling bakers'* dermatitis. The flour milling industry went into the question very thoroughly and formed a dermatitis committee to report on the incidence of dermatitis within their province. The conclusions were that "workers in flour mills are affected to a less extent than the average population."

There is, it has been found, a definite relation between the occurrence of dermatitis and hand-kneading of dough. Dermatitis among bakers in this country may, it is suggested, be attributed to the physical reaction of contact—often long continued—of the skin with dough, which is hygroscopic. In the heat of the bakehouse sweat and sebaceous glands are active; the baker has in general a soft hyperidrotic skin. Maceration of the horn cells results in loss of the integrity of the natural protectors of the skin. Together with these changes coarse abrasions may readily be caused when the dried and hardened dough is removed, perhaps from a hypertrichotic surface, by the use of a rough sacking towel, or by the assistance of a blunt instrument.

How great a part in the original or subsequent attacks is played by protein sensitisation is worthy of consideration, but it is probable that the prevention of dermatitis among bakers lies in the preservation of the normally protective horny layer of the epidermis with the avoidance of conditions favouring excessive sweating.

It is likely that dermatitis among bakers with the increasing use of mechanical methods resulting in little or no contact with flour and dough will become rarer, but until the condition is no longer met with, each instance is of importance, particularly to the baker himself, because of the often late age of onset and the marked tendency for recurrence.

Workers in certain *woods* share with bakers and some others this very marked tendency for recurrence of dermatitis. It is usual for dermatitis from woodwork to show itself soon after exposure first on the face and neck, with great swelling of tissues. The hands are generally affected later. Sweating is an important factor in causation.

Teak dermatitis is the best known, but other woods less well recognised, producing severe reactions, are Brazilian walnut[6] from which eleven cases occurred among 100 men, patch tests being positive; and Rumanian pine. This wood, used for soundboards of pianos, has been known to produce a severe case of dermatitis in a man aged 56. Rosewood from British Honduras for xylophone keys appeared to have produced typical attacks in two elderly men of experience, who had worked for many years with teak and boxwood without untoward effects. Dermatitis from East Indian satinwood (chloroxylon swietenia) has been the subject of exhaustive research by Cash.[7] The crystalline alkaloid, chloroxyline, the amount of which varied considerably in different specimens of satinwood, was found to produce in two out of three subjects an insidious and severe experimental dermatitis—whilst a resin present in the wood was found to be capable of arousing dermatitis in those who have been rendered abnormally susceptible by chloroxylonine action. Sennear[8] reviewing the question of dermatitis from woods has collected a number of interesting statements as to the nature of the irritants in wood. Non-saturated resinous acids and alkaloids, some of which have been isolated, are considered chiefly responsible by different authorities. In the case of the Tagayasan nut tree a substance allied to chrysarobin was identified.

Dermatitis from that group of chemicals used in the rubber industry to accelerate the process of vulcanisation—"*accelerators*"—is often severe.

Originally lead salts, inorganic salts, and hydroxides were used as accelerators, but in 1906 the value of the group of organic amines was discovered and substituted. To this group belong "hex"—hexamethylene tetramine (urotropin) and B.B. (montana syrup), the butyaldehyde condensation product of dimethyl-p-phenylene diamine—two accelerators which are known among others to have caused dermatitis. Accelerene is paranitrosodimethyl amine and has caused a number of cases. Trimethylamine is a slow accelerator, but it has the advantage of not discolouring rubber where light articles are being made. Dermatitis from its use, however, is reported from Australia.

Practical experience indicates that a chain of circumstances is generally required for the occurrence of more than an occasional case of dermatitis from accelerators. It seems likely that sweating and dry heat plays an important part in the occurrence of such cases, and that friction as well as heat is necessary. The results of experimental work suggest that the use of lotions consisting of the appropriate chemicals might be of value in preventing dermatitis from accelerators.

French polishers and stainers with the trend of fashion are using less bichromate than formerly. Dermatitis that occurs in this group of workers is more often attributable to the use of overstrong soda water to remove the stains from the skin. Experiments show that only ½ lb.–¾ lb. of washing soda to the bucketful of water (roughly two gallons) will remove the stains, but French polishers like to make the solution stronger to save time and then often neglect to rinse off the alkali.

A painter does not as a rule contract dermatitis from paint but from washing with turpentine or its substitutes. The application of cotton seed oil on the hands before using paint makes its removal simple and the same is true of printing ink.

A curious condition of peri- and hyp-onychial dermatitis was found in those constantly handling *flower bulbs.*[9]

It is at first sight curious that the tulip bulb should be the chief offender, for if friction were an important factor the bulbs of hyacinths, narcissi, and daffodils should be prominent. The tulip bulb is peculiar in that it is protected by a single-layered and rather delicate testa which readily splits and exposes the substance of the bulb. Long-nailed workers seemed more susceptible, and the expression of juice from the bulb substance has been found experimentally to produce dermatitis, without previous trauma, around the nails. This effect of handling tulip bulbs, judging from the interest and statements of the general public, seemed a rather common experience.

More recently the sequel to these observations has been studied. I had an opportunity of examining a large number of women cropping and packing spring flowers. The lesions found were of two groups—one, a sparse vesiculo-papular rash on the forearms, and the other, peri- and hyp-onychia. It seemed that the first was caused by handling daffodils and narcissi ("lily rash"), while the other was attributed to tulips. It is interesting to have evidence that the lesions produced by handling tulip bulbs are reproduced by the juices of the stalks of these flowers. Fatal cases of dermatitis, fortunately rare, are not unknown; one of these was a girl who, after apparent recovery from "lily rash," had a recurrence while handling tulips. Finally, while in contact with chrysanthemum plants, the skin condition became acute and septic infection brought about the fatal issue.

Conclusion

The recognition of dermatitis as of occupational origin owes much of its inspiration to a knowledge of the irritants actually encountered. Deductions may sometimes be made from the site of origin—for example, lime, sugar, metol, tulip juice, have a predilection for but are not all confined to the nail area. An irritating dust as opposed to a liquid will usually show itself first on the face and neck, as do certain wood dusts, copra dust, and barley. In the latter, *P. ventricosus* is the cause. Perhaps it will be the association with dermatitis of some other more characteristic lesions (chrome ulcers, salt, and lime holes) which will lead to the identification of the causal irritant. Here it may be remembered that formaldehyde, even in very weak solutions, as well as being a very potent cause of dermatitis, can produce a clean cut ulcer not unlike an early "chrome hole." Oil folliculitis is, of course, easy of recognition, but then it is not strictly a dermatitis. Many cases of dermatitis—especially those not of recent origin and those which have been treated—show no helpful individuality. The worker's description of his job is often quite unintentionally misleading. "Draughting in the limes" does not immediately suggest that there has been contact with tanning solutions; nor is it universally known that "wrapping dollies" is a process in the manufacture of dry batteries, in connexion with which manganese and carbon should be recalled. There are endless conundrums but their elucidation really depends on persuading the patient to describe what he does in his own words, which, if he is a technician, may be far from simple! So many and varied are the causes of industrial dermatitis that a study of this subject emphasises yet again the truth of Bordet's words, "La vie est le maintien d'un équilibre incessament menacé."

GLANDULAR FEVER AND INFECTIOUS MONONUCLEOSIS*

BY H. LETHEBY TIDY, M.D. Oxon., F.R.C.P. Lond.

PHYSICIAN TO ST. THOMAS'S HOSPITAL, LONDON

(*Concluded from p. 186*)

Morbid Anatomy

FATAL cases of glandular fever are very rare, and usually have septic or other complications; but lymph glands have been removed at biopsy on many occasions. Two principal changes are recorded both of which may be present together. These are lymphoid hyperplasia, which is specially observed in glands removed in the early stages of the glandular type, and hyperplasia of the reticulo-endothelial tissues. The second has been emphasised in recent records, especially those of McLean, Pratt, and du Bois. Both Pratt and McLean's cases were of the febrile type with maculo-papular eruptions.

Pratt had two glands removed during his own attack. The first shows reduction of lymphocytes with hyperplasia of the reticulo-endothelium and numerous swollen cells with large, flat, pale-staining nuclei, which may be accepted as reticulo-endothelial cells. The second gland removed later shows mainly increase of fibrous tissue and scarcity of lymphoid tissue.

It has been suggested that the hyperplasia of the reticulo-endothelial cells is the cause of the appearance of plasma cells or monocytes in the blood. It may be doubted if the changes would differentiate these glands from non-specific lymphadenitis.

On the condition of the bone-marrow there is no satisfactory report.

The Blood Picture

ERYTHROCYTES

There is no change in the red cells and no anæmia in the ordinary course of the illness. The thrombocytes are not affected. During convalescence a slight secondary anæmia may slowly develop and persist for several months.

LEUCOCYTES

The characteristic manifestation is the development of an absolute lymphocytosis, but it will be shown that not only the lymphocytes but all the leucocytes are affected.

The total *number of leucocytes* usually does not exceed, or materially exceed, the higher limits of normal. The counts commonly lie between 6000 and 15,000 per c.mm., but there are numerous instances in which it has greatly exceeded this figure. Hueper, in a single case, records figures of 50,000 to 87,000, but the diagnosis is very doubtful. Stepp and Wendt are credited by Schwarz with a count of 80,000, but this is a misapprehension, for the highest figure in their article is 27,000. All counts of over 40,000 which I can find in the literature are given in Table I., and it will be seen that they are all in infants or young children. Both the lymphocytes and the polynuclears are increased. The highest number in my own experience is 35,000 in a child of six years, and 33,000 in an adult. There is no recorded case of over 40,000 in an adult. It may be accepted that in adults and children over seven years, figures over 20,000 are unusual, over 30,000 are rare, and 40,000 is the maximum. In infants and young children, 60,000 may be reached exceptionally, but it will be noted that 85 is the highest percentage of mononuclears in these cases. The high numbers together with extreme mononucleosis such as 99 per cent., which are common in lymphoid leukæmia, never occur in glandular fever.

TABLE I.—*Hyperleucocytosis*

Author.	Age.	Total leucocytes.	Mn. per cent.
Feer	1 year	63,000	81
de Bruin	1½ years	63,000	78
Nelken	4 ,,	58,000	59
Feer	1 year	54,500	64
Price	7 months	44,000	84
de Lange	10 ,,	41,200	85

Mn. = Mononuclears.

Morphology of Polynuclear Cells.—Examination of the nuclei shows frequently a "shift to the left"—that is, towards more primitive cells. This suggests a strain on the myeloid tissues of the bone-marrow. The marrow, however, cannot be exhausted or aplasic as it is capable of responding, at least temporarily, with a polynucleosis to an ordinary infection such as otitis media, or a stimulus such as milk injections. The eosinophils are stated by some authorities to be low in the early stages and high in convalescence, but from a study of the figures it does not seem possible to form any definite conclusions.

TABLE II.—*Glandular Type: Polynucleosis*

Author.	Age.	Glands palpable.	Day of blood count.	Leucocytes.	Pn. per cent.

			21	7,700	37

* Relapse. Pn. = Polynuclears.

Polynuclear Cells: Polynucleosis.—A definite polynucleosis may be present in the prodromal and initial stages of the glandular type (Guthrie and Pessel, Scheer, Tidy). As an absolute lymphocytosis is the outstanding feature and usual criterion of glandular fever, it is important to note this. In the febrile and anginose types nothing is known of the blood at the onset. In the anginose type lymphocytosis has always been present by the time the faucial changes have developed.

---

* The Lumleian lectures for 1934, delivered to the Royal College of Physicians of London on March 15th and 20th.

n the glandular type in a boy under me, aged years, at the first count, the leucocytes were 600 and the polynuclears 85 per cent. He com- ined of a sore-throat, but the glands had not arged at that time.

Although usually the polynucleosis disappears idly at the time of the glandular enlargement, it y sometimes, especially if severe, persist for a few 's. Illustrations of polynucleosis at different ages given in Table II., including one case during a rudescence of the glandular enlargement. The e with 31,000 leucocytes and 79 per cent. of poly- clear cells was undoubtedly glandular fever.

Polyneucleosis only occurs in the initial stage, ver developing during the course, and is always nsient. The extreme instances of hyperleuco- tosis given in the previous section also occurred ly in the attacks, the numbers always subsequently ling.

Glanz-mann	1	3	3,000	25 (600)	75 (2,400)	1	Glandular
Becker	25	1	3,800	42 (1,600)	58 (2,200)	1	Glandular (and rash)
		15	12,000	25 (4,000)	75 (8,000)	1	
Glanz-mann	4½	3	10,000	9 (900)	91 (9,100)	1	Glandular (and rash)
		4	6,300	4 (250)	96 (6,000)		
		10	7,000	9 (630)	91 (6,400)		
		16	6,500	27 (1,750)	73 (4,750)		
		31	8,000	24 (1,900)	76 (6,100)		

Leucopenia.—Low total counts below 4000 per c.mm. re rare, the recorded cases being given in Table III. 'he leucopenia occurs only at the onset or early in he attack; it never develops during the course, hus resembling the polynucleosis. It is essentially ue to diminution of the polynuclear cells and the otal number always rises later. The neutropenia is xtreme in several instances. Clinically the course s often severe and atypical.

Extreme neutropenia may also occur with an bsolute lymphocytosis, as in Glanzmann's case in 'able III. All these cases recovered. Lymphopenia, n absolute reduction of mononuclear cells, is not ecorded.

During convalescence, and often for long periods ubsequently, a slight leucopenia is common. This is mainly due to reduction of polynuclear cells, and thus is associated with an increased percentage of lymphocytes.

Variations in Polynuclear Cells.—The polynuclear cells thus appear to react early to the virus, resulting in an initial polynucleosis or occasionally a neutropenia. In either event, at the end of a few days, the polynuclears tend to be at or somewhat below normal. Subsequently they vary round this figure.

Mononuclear Cells.—The lymphocytosis and the glandular enlargement usually develop together on or about the same day in all types. It may, however, precede the glandular enlargement by a day or two, while occasionally, as noted previously, an early polynucleosis may overlap the adenitis. The lymphocytosis may develop in the space of a day or two.

The lymphocytes reach their maximum at most a few days after the first development of lymphocytosis. The polynuclears may by that time have reached their minimum, so that the relative percentage of mononuclears becomes very high. The lymphocytes then commence to diminish, at first rapidly for a few days, and then more slowly. In Table IV. are examples of typical courses. No. 1 is a case of Sprunt and Evans. Nos. 2 and 3 were cases under me exhibiting an early normal count.

TABLE IV.—*Glandular Fever: Normal Course*

Case.	Age.	Illness day.	Total leucocytes.	Poly-nuclears.	Mono-nuclears.

The degree of lymphocytosis does not show any direct relation to the size of the glands, but in an individual case the lymphocytosis approximately follows the same course as the glands, and persists or falls with them. It has been known, in many cases, to persist over long periods, even several years.

The highest percentage of mononuclear cells recorded is 97·5. The leucocytes numbered 20,000 (Ireland). Figures of 99 per cent., such as occur commonly in lymphoid leukæmia, are never found. All percentages over 90 are rare; figures between 70 and 80 per cent. are common, but 60 and 70 per cent. are even more frequent.

The mononuclear cells appear to react less rapidly than the polynuclears and are little altered during what may be called the febrile stage. But with the occurrence of glandular enlargement, affection of the mononuclears is constant.

Morphology of Mononuclear Cells.—The mononuclear cells in glandular fever are extremely varied in type. With regard to their morphology the following general points may be stated:—

(1) The mononuclear cells are not myeloid in origin.

(2) Numerous types of abnormal mononuclear cells are usually present simultaneously. This is in marked contrast to lymphoid leukæmia.

(3) The predominant cell may be different in different cases; it may also change with great rapidity in the course of an individual case.

(4) Similar forms occur in all types of glandular fever.

The nature of some of the abnormal cells is difficult to decide. Observers are in substantial agreement as to their appearance and staining reactions, but differences arise as to their classification and origin, and as to whether certain cells are lymphocytes or "monocytes." A monocyte in this sense is a cell which we commonly call a plasma cell, the origin of which is supposed to be from reticulo-endothelium.

In the blood films grades of lymphocytes can be traced, varying more and more from the normal and approaching more and more to the characteristics of plasma cells. It cannot be said that a point can be fixed beyond which it is impossible for an abnormal lymphocyte to pass, and that all cells beyond it must be plasma cells. Certainly no two authorities would agree on the same point. I have carefully studied the cells in many cases of glandular fever and cannot recognise any criteria by which certain abnormal forms of lymphocytes and monocytes can be differentiated. Supravital staining (McLean, Wilson and Cunningham, Lawrence and Todd) unfortunately leaves one in doubt at exactly the same point as other methods.

Probably cells, typical and atypical, are present from both forms of tissues, and certain atypical cells of the two groups are indistinguishable. This accords with recent histological studies of glands which suggest stimulation both of the lymphoid and reticulo-endothelial tissues.

Classification of Mononuclear Cells.—The mononuclear cells occurring in glandular fever may be divided into three groups:—(1) Normal lymphocytes. Some normal cells are always present and may form a high percentage. As convalescence sets in there is a return to predominance of small lymphocytes. (2) Primitive lymphocytes. (3) Abnormal mononuclears.

Primitive Lymphocytes.—There are two common types, both of which are known as either "lymphoblasts" or "leucoblasts." (*a*) Large cells with clear, slightly basophilic cytoplasm. No azur granules. Vacuoles usually absent but occasionally present. The nucleus is pale, may be slightly irregular with fine chromatin and no nucleoli. (*b*) Large cells with cytoplasm distinctly basophilic, but staining irregularly. In the nucleus one or often more nucleoli are usually present; the chromatin is irregularly distributed, and the nucleus stains dark.

Abnormal mononuclear cells are of such varying types that one can only *indicate the points on which they differ* from the normal. Practically all combinations of such variations can be observed. (1) Size: larger than normal. (2) Shape of nucleus: may be round, oval, or bean-shaped, or may be markedly indented as in the Rieder cell or normal large mononuclear. (3) Chromatin of nucleus: no standard type; network often irregular. (4) Staining of nucleus: darker than normal. (5) Cytoplasm: stains more basophilic than normal. Vacuoles may be present, sometimes to a marked degree.

The commonest predominant cell is somewhat larger than a small lymphocyte; the cytoplasm is more basophilic than a normal large lymphocyte, and the nucleus is darker and indented.

Combinations of the variations classified above, in their advanced forms, give cells resembling (or identical with) normal or abnormal plasma cells.

BLOOD CHANGES IN FEBRILE TYPE

There is little knowledge as to the course of the blood changes in the early stages of this type. Table V. contains all the reliable examinations which I have been able to find. Many counts were made under a diagnosis of typhoid and were not repeated.

In Stage 2 there is slight but definite indication of lymphocytosis. In Stage 3 lymphocytosis invariably develops. Its subsequent course is the same as in the glandular type, but is more prolonged with the continuation of the pyrexia and enlarged glands.

TABLE V.—*Febrile Type: Typical Course*

Day of illness.	Author.	Age.	Rash (day)	Glands (day).	Bd. Ct. (day).	Total leucocytes.	P.M.N	Mn.
5–10	Longcope	30	5	22	6	3,000	57	43
					7	3,400	60	40

	,,	40	5	24	27	13,000	43	57
	,,	26	4	10	27	29,000	12	88

Atypical cases of the febrile group occasionally occur, in which the development of rash and glands are not in the usual order or stages. Blood counts from a few such cases are given in Table VI. The blood is as erratic as the clinical features but the general lymphocytosis accompanies the glandular enlargement.

TABLE VI.—*Febrile Type: Atypical Courses*

Author.	Age.	Rash (day).	Glands (day).	Bd. Ct. (day).	Total leucocytes.	Polynuclears.	Mononuclears.

BLOOD CHANGES: GENERAL CONCLUSIONS

The myeloid tissue is affected from the onset. It may react initially either by a polynucleosis or a neutropenia. In either case the total number quickly returns to about normal figures.

The lymphoid tissue appears to respond to the infection less rapidly, though finally to a greater degree. Both the type of cells and the morbid histology of glands suggest that all mononuclear cell tissue is affected.

The suggestion that the blood changes are due to the circulation being flooded with lymphocytes from the enlarged glands cannot explain the early polynucleosis, or the leucopenia with neutropenia, or such a count as 6000 leucocytes with 96 per cent. lymphocytes. It is evident that the virus of glandular fever transiently affects all the blood-forming tissues, and no single blood picture is typical of the disease.

Pathogenesis

The Virus.—Bacteriological examinations of the blood, glands, and emulsions of the glands have been uniformly negative except for a few results which may be ascribed to secondary invaders or contaminations. Nyfeldt's "Bacterium monocytogenes hominis" has not been confirmed. Spirochætes are not present. Streptococci and Vincent's organisms have been isolated repeatedly from the fauces but are not seriously considered as the cause.

With regard to animal experiments, only Bland's investigations are promising. During the 1930 epidemic he injected patient's blood into rabbits. Results were negative except when the blood was taken during the febrile period in the early stages. Such inoculations produced a rapidly fatal febrile disease, and could be transmitted to other rabbits. The infection could be transmitted to monkeys, in which it produced a disease with fever, enlargement of lymphatic glands, and a mononucleosis with primitive lymphocytes. A protozoon of the genus toxoplasma was identified. Toxoplasmosis is natural to many animals, including rabbits, but Bland states that this cannot be transmitted to monkeys. Unfortunately febrile cases are rarely diagnosed in the early stages, except during an epidemic, and Bland has had no opportunity of continuing this work. The question whether this is a specific toxoplasma remains undecided.

Heterophile Antibodies.—The presence of heterophile antibodies in glandular fever is a curious phenomenon discovered by Paul and Bunnell. The amount present in glandular fever was consistently and markedly in excess of that in any other condition examined, with the exception of one unclassified blood change. Sprunt states that these results have been confirmed at Johns Hopkins Hospital. Further investigations are required.

Diagnosis

Glandular fever is a febrile disease with general glandular enlargement and lymphocytosis. When the characteristics are present and recognised the diagnosis is easy. It may, however, be difficult or temporarily impossible before the characteristics have developed or in the presence of certain special features. The special difficulties are here discussed.

GLANDULAR TYPE

(1) *Acute Lymphoid Leukœmia.*—This is rarely difficult; in glandular fever the patient is not seriously ill, there is no anæmia, many types of mononuclear cells are present simultaneously, the total and differential counts do not reach the figures usually present in leukæmia, and recovery is rapid.

(2) *Sepsis and Mumps.*—In glandular fever there may be slight swelling of the skin over a mass of glands in the neck and polynucleosis may be present temporarily. In such circumstances there may be temporarily a close resemblance to sepsis or (except for the blood) to mumps at its onset. Definite œdema and a mass suggestive of sepsis or mumps does not occur, and the parotid gland is never affected.

There should be no confusion with tuberculosis, Hodgkin's disease, or syphilis.

ANGINOSE TYPE (MONOCYTIC ANGINA)

(1) *Diphtheria.*—Glandular fever angina differs clinically from diphtheria in the long prodromal period, the long febrile course which may occur, in the general glandular and splenic enlargement, and in its mild constitutional effects, and in the tendency to recurrences. In diphtheria there is an absolute polynucleosis increasing with the severity of the infection which never alters to a lymphocytosis.

(2) *Vincent's angina* does not cause a membranous condition or lymphocytosis.

(3) *Scarlet fever* produces a persistent polynucleosis. Rashes are practically unknown in anginose glandular fever.

FEBRILE TYPE

Diagnosis from typhoid and various fevers may be impossible until the glands and lymphocytosis develop.

The visceral types which have been mentioned are an obscure group. Diagnosis rests on the absolute lymphocytosis.

ERUPTIONS

(1) *Maculo-papular Eruption.*—The diagnosis clinically from typhoid may be temporarily very difficult.

(2) *Rubelliform Eruption.*—In rubella it is generally accepted that the leucocytes are below normal numbers and the plasma cells are especially increased, while glandular enlargement rarely includes the axillary group. Glanzmann believes that the diagnosis may be impossible.

It is possible that in the heterogeneous group of conditions, which Duke described as "fourth disease," are included cases of glandular fever.

BLOOD CHANGES

It is suggested that there is a closely allied group of "lymphotropic viruses" which produce lymphocytosis (Schwarz and Lehndorff). The group would include whooping-cough, mumps, glandular fever, and rubella; no doubt there are others, possibly Mossman river fever and Haberfeld's disease. The blood changes of glandular fever may approximate to agranulocytosis, which probably is not a single entity.

Treatment and Prophylaxis

Treatment is purely symptomatic. In simple cases of the glandular type the patient should be kept in bed until the temperature is normal and the main mass of glands has subsided. In prolonged febrile types some general exhaustion may develop and need nursing on the usual principles in pyrexial states. Attempts at specific treatment with intravenous injections of arsenical preparations or mercurochrome have proved valueless. Diphtheria antiserum is useless.

During convalescence tonics and iron are indicated. School-children often exhibit some degree of debility for six months or a year. They are fit for ordinary school routine but should not be unduly blamed for falling below their usual mental and physical standard.

Isolation should be carried out in accordance with the dictates of common-sense for a disease which is undoubtedly infectious, but only of a moderate degree of infectivity and with a favourable prognosis. It is clear that the infectivity is greatest in, and possibly even confined to, the first few days, and that children are more susceptible than adults.

With regard to schools it should be remembered that a single case with reasonable precautions rarely infects other members of a family household, but that two or three cases together in a school will commonly result in the infection of most of the children.

Conclusions

1. Glandular fever is an acute infectious disease, characterised by fever, glandular enlargement, and blood changes (especially mononucleosis), and sometimes by severe faucial changes. No age is immune, but children are most liable to infection.

2. Three principal clinical types can be recognised: (1) glandular or Pfeiffer's type; (2) anginose type (monocytic angina); (3) febrile type.

3. Suppuration of glands is very rare.
4. Eruptions are common in the febrile type and its variations. The usual forms are maculo-papular, resembling typhoid, and rubelliform, especially in children.
5. All blood-forming tissues are affected. The myeloid tissues tend to react more rapidly, producing initial transient polynucleosis or neutropenia. The lymphoid tissues react more slowly producing mononucleosis. The total leucocytes rarely exceed 40,000 per c.mm. but may reach 60,000 in young children.
6. The mononuclear cells are increased both relatively and absolutely. Numerous types of abnormal mononuclear cells tend to be present simultaneously. The abnormal cells may represent any or every type from lymphocytes to plasma cells (monocytes). The predominant cell may vary in different cases, and may alter in type in the course of an individual case.
7. The prognosis is favourable and the mortality in healthy subjects is negligible.
8. The virus is unknown but is probably transmissible to monkeys.

TWO CASES OF BASOPHIL ADENOMA OF THE PITUITARY GLAND

BY DOROTHY S. RUSSELL, M.D. Lond.
MEMBER OF SCIENTIFIC STAFF, MEDICAL RESEARCH COUNCIL

HORACE EVANS, M.D., M.R.C.P. Lond.
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL; AND

A. C. CROOKE, M.B. Camb.
GROCER'S RESEARCH SCHOLAR

(From the Bernhard Baron Institute of Pathology and the Medical Unit, the London Hospital)

THERE is a certain inconstancy in the clinical features that are held to be characteristic of the condition described by Cushing (1932, 1933) as "pituitary basophilism." In his latter paper Cushing identified the syndrome in 14 cases with verified pituitary adenomata. In 4 of these the adenoma appears to have been other than basophil.

Accepting the remaining 10 cases and adding the subsequently reported cases of Kepler et al. (1933, 1934) and of Craig and Cran (1934) it appears that the most constant clinical features are as follows: (1) adiposity of face and trunk (11 positive, 1 negative); (2) hirsuties (11 positive, not mentioned in 1—the only male subject); (3) amenorrhœa or impotence (9 positive, irregular menstruation in 1, hysterectomy had been performed in 2); (4) osteoporosis (9 positive, not mentioned in 3); (5) raised blood pressure (8 positive, not mentioned in 4); (6) striæ atrophicæ of the abdominal skin (7 positive, not mentioned in 5). A less constant feature is: (7) glycosuria (4 positive, 3 negative, not mentioned in 5). In Cushing's first paper he also notes as characteristic of the syndrome "a tendency to erythræmia, a count exceeding 5 millions having been present in five of the nine cases in which blood counts were recorded." Perusal of the case reports shows, however, that in two only did the red cell counts exceed 5 millions and in neither was a basophil adenoma demonstrated. In one of the proved cases of basophil adenoma the red cell count "approximated 5 millions" while in the rest it was either below this level or was "normal." Of subsequently reported cases there is a note of the blood count in 7. In 1 case only (Moehlig, 1932) did the red cell count appreciably exceed the range of 3,940,000 to 6,080,000 for normal women (Vaughan, 1934). In this the count was 6,850,000. In Craig and Cran's case the count was 6,190,000. In the other 5 cases it did not exceed 5,290,000.

The first of the following two cases is interesting not only as the second verified case in a male subject but also because several atypical features have emerged in the course of the examination. The second case, in a female, is of importance because so few of the features regarded as characteristic of the syndrome were present.

The First Case

CLINICAL

A male aged 31, a commercial traveller, was first admitted to the London Hospital on March 15th, 1932 (Reg. No. 30414, 1932, Med.), under the care of Prof. Arthur Ellis. He complained of intermittent headaches and occasional attacks of epistaxis during the previous three years. At the onset of these symptoms he had begun to get stout and his weight had increased in about twelve months from 69·85 to 84·82 kg (Figs. 1 and 2). The greater part of this increase in weight was, however, lost during the next two years, and by the time he came under our observation it was 73·48 kg. His wife had noticed that the adiposity was mainly about the face and abdomen. One year before admission he had noticed swelling of the ankles, shortness of breath, and nocturnal frequency. At this time he had been told that his blood pressure was high. Three months before admission he had begun to get severe morning headache associated with vomiting.

He was a married man but his wife had had no children and there had been no miscarriages. During the year before admission there had been impotence. He had never complained of any disturbance of vision, nor had he ever noticed any hæmaturia. At the age of ten he had been in hospital with enteric fever; the urine at that time was reported as clear.

On examination he was an obese, plethoric man with a red face and highly coloured mucous membranes. The distribution of hair and the external genitalia appeared normal. The adiposity was most obvious in the lower part of the face and in the abdomen; in the skin of the abdominal wall there were conspicuous striæ atrophicæ. There was no demonstrable œdema. The heart was definitely enlarged, the apex-beat being well outside the nipple line; the blood pressure was 210/140 mm. Hg. Examination of the fundi showed a well-marked albuminuric retinitis: "there was marked arterial thickening, multiple small retinal hæmorrhages, many small glistening patches, and also larger and softer patches of exudate" (Mr. Charles Goulden). *Urine:* persistent cloud of albumin; no macroscopic hæmaturia; a few leucocytes and red corpuscles with occasional granular and hyaline casts in deposit; specific gravity 1010 to 1025 with no tendency to fixation. The daily volume excreted varied up to 78 oz. *Renal function:* blood-urea, 0·036 per cent.; phenolsulphonephthalein, 19·1 per cent. in two hours; urea excretion, 73 per cent. of normal. *Blood count:* red cells, 5,600,000; hæmoglobin, 88 per cent.; colour-index, 0·78; white cells, 7000.

The patient was observed in hospital for five weeks. The combination of headache, obesity, and impotence suggested the possibility of an adenoma of the pituitary gland, but a radiological examination of the skull revealed no abnormality. The renal function tests were repeated several times and always yielded results within the limits of normal. A diagnosis of hyperpiesia was therefore made, the retinal changes suggesting a malignant hypertension. For a time he responded to treatment with luminal, venesection, and restricted diet. The blood pressure came down to 160/120 mm. Hg and his weight was reduced to 63·67 kg. After discharge he was seen at the nephritis clinic by one of us (H. E.) at frequent intervals during the following sixteen months. He continued to complain of headache, giddiness, and insomnia, and later of precordial pain, dryness of the mouth, and thirst. On one occasion only (Feb. 3rd, 1933) did he complain of pain in the back. The blood pressure remained round about 210/130 mm. Hg. Towards the end of July, 1933, the dyspnœa and precordial pain became more intense, and spontaneous purpuric hæmorrhages appeared in the skin of both legs.

On August 8th he was readmitted to hospital. *On examination* he was very distressed and dyspnœic. The tongue was dry and furred. There was no œdema. Large purpuric hæmorrhages were present in the skin of both legs. The blood pressure was 205/145 mm. Hg. Otherwise the physical signs were as before. There was no definite clinical evidence of heart failure. *Urine:* cloud of albumin; no macroscopic hæmaturia; specific gravity, 1005–1015; daily volume up to 49 oz. *Renal function:* blood-urea, 0·12 per cent.; phenolsulphonephthalein, a trace in two hours; urea clearance, 22·8 per cent. of normal. *Blood count:* red cells, 3,200,000; hæmoglobin, 30 per cent.; colour-index, 0·47; white cells, 5600. He was temporarily relieved by venesection but died in uræmia one week after admission.

SUMMARY OF NECROPSY

Nephritis repens with very great cardiovascular hypertrophy. Basophil adenoma of pituitary gland. (P.M., 351, 1933.)

Moderate general atheroma. Degenerations, necroses, and formative changes in arteries of kidneys, pancreas, suprarenal bodies, spleen, myocardium, and liver. A few focal areas of degeneration, necrosis, and hæmorrhage in suprarenal bodies, and of necrosis and interstitial fibrosis in pancreas, due to arterial changes. Œdema and post-mortem digestion of pancreas. Œdema, focal areas of engorgement, and slight chronic inflammation of pulp of spleen. Lipochromic and slight fatty degenerations of centres of lobules of liver. Partly organised vesicular hæmorrhages, œdema, and collateral emphysema in lungs. Many hæmorrhages (up to 5·5 × 4 cm.) in skin of trunk and limbs, especially legs. Many striæ atrophicæ in skin of abdomen. Excess of subcutaneous fat (up to 3·5 cm. thick) in abdominal wall. No excess of fat on limbs. Normal amount of hair of male distribution. No deformity of spine. Teeth sound. No abnormality in bones. Red, adipose-hæmopoietic marrow in ribs, vertebral bodies, and upper three-quarters of shaft of femur. Œdema of active testicles. Normal thyroid and parathyroid glands. Thymus obscured by adipose tissue. Œdema of brain. Mucous catarrh and congestion of stomach. Internal hæmorrhoids. Caseous tuberculous nodule (0·5 cm. diam.) in lower lobe of right lung. A few hæmangeiomata (up to 0·5 cm. diam.) in liver.

Weights: body, 60·84 kg. (height, 1·668 m.); heart, 687·5 g.; liver, 2239·6 g.; kidneys, 326 g.; spleen, 269·3 g.; brain, 1289·9 g.; pancreas, 83 g.; suprarenal bodies, 20·8 g.; testicles, 47·7 g.; thyroid gland, 16·75 g.; pituitary gland, 0·7 g.

MACROSCOPIC EXAMINATION

The *pituitary gland* was of normal size (1·4 × 1·15 × 0·9 cm. deep). The angle between the anterior and right borders of the gland was occupied by a projecting opaque creamy-white nodule (up to 0·6 cm. from side to side × 0·4 cm. from before back × 0·65 cm. from above downwards), which on section was greyish-white and sharply circumscribed. The posterior lobe was very small and was partly separated from the anterior lobe by a cyst (0·3 × 0·2 cm.) containing clear honey-like material.

The *kidneys* were of normal size with pinkish-red subcapsular surfaces, which were studded with yellowish and greyish-white granules and a few petechiæ. The cortex was narrow and its pattern blurred. The glomeruli appeared prominent. The demarcation of cortex from medulla was indistinct. The arcuate arteries were abnormally conspicuous. The *suprarenal bodies* were large but did not exceed the limits of normal as they represented 0·0341 per cent. of the body-weight (see figures in Leyton, Turnbull, and Bratton, 1931). The cortex contained abundant lipoid and a conspicuous pigment zone. No adenomata were seen. The medulla was scanty. Three *parathyroid glands* were identified. They measured: (1) 0·6 × 0·45 × 0·4 cm.; (2) 0·6 × 0·5 × 0·4 cm.; (3) 0·65 × 0·4 × 0·3 cm.

MICROSCOPIC EXAMINATION

The pituitary gland was divided horizontally into two parts, embedded in paraffin and sectionally serially. The first sections were stained with Ehrlich's hæmatoxylin and eosin, Weigert's iron hæmatoxylin and van Gieson's mixture, Weigert's fuchselin and neutral red. The remaining sections were stained with Mallory's acid-fuchsin aniline-blue. Other tissues examined were as follows: parathyroid, thyroid, pineal, and both suprarenal glands; thymus, testis, tail of pancreas, both kidneys, lung, myocardium, spleen, liver, skin, marrow of femur, lumbar lymphatic gland, cervical sympathetic ganglion, and arch of aorta. The staining methods used were the first three of those enumerated above. Portions of the fifth rib, head and shaft of femur, and a lumbar vertebra were decalcified in Müller's fluid for three months followed by 0·5 per cent. nitric acid in 4 per cent. saline formaldehyde. Herxheimer preparations for fatty substances were made of spleen, both kidneys, liver, myocardium, left suprarenal gland, and aorta.

The pituitary gland.—The nodule in the anterior lobe is a mass of basophil cells enclosed by a zone of stout collagen fibres (Fig. 3). The cells are of approximately normal size. In many places their borders are indefinite and the appearance is suggestive of a syncitium. Some of the cells have two or three nuclei. The cytoplasm of nearly all the cells is crowded with coarse basophil granules. The few cells in which these granules are absent are the smallest; they cannot be distinguished from ordinary chromophobe cells. The rest of the gland appears normal. A cyst, filled with hyaline eosinophil material and lined with a low cubical epithelium, occupies the pars intermedia and projects into the posterior lobe. The posterior lobe is small and contains a few groups only of basophil cells in the part that abuts on the pars intermedia.

The kidneys show an advanced stage of chronic Bright's disease of the kind that has been designated by one of us (Russell, 1929) as nephritis repens, type 4. The vascular changes in these and in the other organs of the body will be dealt with in a future paper; we believe them to be an association of toxic nephritis.

The lungs.—In portions of the upper lobes of the right and left lungs that had shown ill-defined finely granular areas of consolidation to the naked eye large groups of bronchioles, alveolar passages and infundibula contain red corpuscles and fibrin. The margins of these plugs of exudate are occasionally infiltrated with fibroblasts, and in a few respiratory bronchioles the whole plug is replaced by fibroblasts and collagen fibrils. Elsewhere the vesicular tissue contains albuminous coagulum or is distended by emphysema. There is no general congestion of the grade seen in "back pressure" lungs. There are no recognisable abnormalities in the blood-vessels.

Petechia in skin of chest.—A mass of red corpuscles and relatively abundant fibrin lies in the lower margin of the dermis. There are no recognisable abnormalities in the vessels.

Endocrine glands.—The cortex of the *suprarenal bodies* is loaded with lipoid. The normal pattern of cortex and medulla is preserved except where, in the cortex, focal areas of degeneration, necrosis, and hæmorrhage result from lesions of the capsular arterioles. Dr. H. W. C. Vines has kindly stained a section by his ponceau-fuchsin method (Broster and Vines, 1933) and finds that the reaction is negative. The islets in the tail of the *pancreas* appear unaltered. A few focal necroses and areas of increase of collagenous stroma in other parts of the gland are referable to the vascular changes present. In the *testis* spermatogenesis is in active progress and spermatids and spermatozoa are numerous. There is great rarefaction of the interstitial tissue by œdema. The interstitial cells are sparse and scattered in small groups. Almost all the vesicles in the *thyroid gland* contain colloid and many are considerably distended therewith. There is very little sign of active secretion. The *thymus* is represented by slender branching cords of thymic reticulum. These contain a very few Hassal bodies and several calcareous spheres, and are expanded in a very few spots by small focal areas of lymphoid infiltration. The *pineal and parathyroid* glands appear normal.

Bones.—There was no abnormality in the histological structure of the bone. Adipose tissue is in considerable excess of hæmopoietic in the red marrow of the femur, but in slight minority in the rib and vertebra. The hæmopoiesis is normal in character.

The Second Case

CLINICAL

A married woman of 33 was admitted to the London Hospital in coma during the night of Jan. 19th, 1934, shortly after the onset of a stroke (Reg. No. 40122, 1934, Med.). She was very obese, the fat being of general distribution and not sparing the limbs. Respiration was stertorous. The left pupil was first contracted but later dilated and fixed. The right pupil was dilated and fixed. There was weakness of the right side of the face. An extensor plantar reflex was obtained on the right side. The systolic blood pressure was 240 mm. Hg. Blood-stained fluid was obtained by lumbar puncture. Death took place 90 minutes after admission. The clinical diagnosis was cerebral hæmorrhage.

The husband said that obesity dated back to school-days when the patient had been nicknamed "Fatty." He produced photographs of her at the ages of 14 and 16 in confirmation of this. They had been married ten years and there had been three pregnancies. The first child, born nine years ago, was premature at seven months and died a few days after birth. The second child, born seven years ago, is alive and well. The third pregnancy, four years ago, was terminated between the fifth and sixth months in Guy's Hospital by Cæsarean section. Sterilisation was also carried out. Since that time the menses had been regular to within a day or two of the month, and the patient had led an active, normal life. She did not complain of any symptoms such as headache or backache. Photographs at different periods of her married life showed a physical appearance closely resembling that at the time of death.

Through the kindness of Mr. J. B. Blaikley, obstetric registrar at Guy's Hospital, the following particulars have been obtained concerning the patient's obstetric history. The first two pregnancies had been complicated by œdema and albuminuria. She was said to have been blind for three days at some period during the first pregnancy and to have had mistiness of vision during the second. On Oct. 21st, 1929, she attended her private doctor at the fifth month of her third pregnancy complaining of headache, swelling of the ankles, and nocturia. On Oct. 29th she was admitted to Guy's Hospital where she was found to have œdema and albuminuria. The blood pressure before operation varied from 200/160 to 175/128 mm. Hg. Blood-urea: 0·023 per cent. Urine: albumin from 6 to 15 Esbach units; no macroscopic blood nor pus; numerous hyaline and granular casts in the deposit. A catheter specimen (Oct. 30th) showed a few epithelial cells and occasional leucocytes in the deposit. On Nov. 7th abdominal hysterotomy and sterilisation was performed. Her subsequent progress was good. The blood pressure fell to 130/85 mm. Hg on Nov. 12th, and at this time there was only ¼ Esbach unit of albumin in the urine. Subsequent daily readings showed, however, a steady rise of blood pressure and on Nov. 26th she was discharged with a trace of albumin in the urine and a blood pressure of 164/130 mm. Hg.

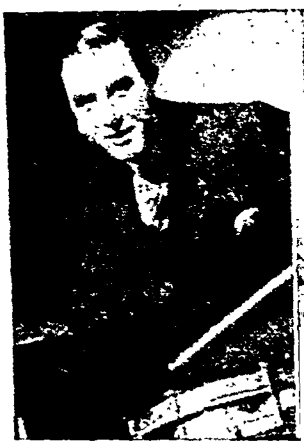

FIG. 1 (Case 1).—The patient five years before his illness.

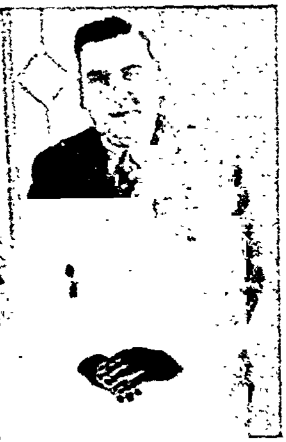

FIG. 2.—Appearance at the height of adiposity.

SUMMARY OF NECROPSY

Pontine hæmorrhage. Cardiovascular hypertrophy. Hyperpiesia. Basophil adenoma of pituitary gland. (P.M., 30. 1934.)

Extension of hæmorrhage in pons to cavity of fourth ventricle and along right crus to lower part of right internal capsule. Great hypertrophy of heart, especially of left ventricle. Moderate general atheroma. A few scattered fat flecks in cerebral arteries. Congestion and slight ischæmic fibrosis of kidneys. Congestion of lungs. Diffuse congestion and œdema of liver. Slight microscopic infiltration of portal systems with small lymphocytes and eosinophil leucocytes. Œdema and congestion of spleen. Œdema, congestion, and extensive post-mortem digestion of pancreas. Post-mortem digestion of body of stomach. Slight chronic cystitis and hypertrophy of urinary bladder. A few fibrous pleural adhesions over middle of outer surface of right lung. Obliteration by fibrous tissue of terminal 7 cm. of 9 cm. appendix. Scar of old Cæsarean section in body of uterus. Scar in left side of external os. Operative removal of Fallopian tubes. Graafian follicles and follicular cysts in ovaries; recent corpus luteum in left ovary. No abnormality in bones. Red marrow (sinks) in upper half and (floats) in remainder of shaft of femur except lower ninth; red marrow in ribs and sternum. Abundant hair over central third of abdomen between umbilicus and pubis, and on upper anterior and inner aspect of thighs. Short black hair in axillæ. Moderate amount of short dark hair on upper and lower lips. Broad black eyebrows. Numerous striæ atrophicæ in skin of lower abdominal wall. Slightly raised melanoma ([illegible] cm. diam.) on outer aspect of left thigh. Very [illegible] black-haired woman with full round face and no obvious plethora.

Weights: body, 84·48 kg. (height, 1·524 m.); heart, 567 g.; liver, 1410·4 g.; kidneys, 318·9 g.; spleen, 233·9 g.; brain, 1452·9 g.; pancreas, 102·3 g.; suprarenal bodies, 14·9 g.; ovaries, 30·8 g.; thyroid gland, 37·3 g.; pituitary gland, 0·9 g.

MACROSCOPIC EXAMINATION

The *pituitary gland* was large (1·3 × 1·4 × 0·75 cm.), but not abnormally so for a multipara. On section the anterior lobe appeared relatively large in comparison with the posterior lobe and had a smooth terra-cotta cut surface. No adenoma was recognised with the naked eye. The *suprarenal bodies* were of normal size, representing 0·0176 per cent. of the body-weight. The cortex contained abundant lipoid and a conspicuous pigment zone. Two or three pinhead cortical adenomata were present in the capsule of the left suprarenal body. The *thyroid gland* appeared to be somewhat bulky and showed a glistening cut surface. The *thymus* contained a moderate amount of visible glandular tissue embedded in a large amount of fat. Three *parathyroid glands* were identified (left upper: 0·7 × 0·4 × 0·15 cm.; left lower: 0·6 × 0·5 × 0·75 cm.; right upper: 0·5 × 0·4 × 0·15 cm.). The *uterus* was rather large. The body was 5·5 cm. long, the cavity 4 cm. wide, and the wall from 1·2 to 1·5 cm. thick; the cervix was 4 cm. long. A narrow scar, 2·5 cm. long, occupied the fundus and upper part of the anterior wall. The endometrium was pale yellowish-white, soft, and up to 0·3 cm. thick. The *ovaries* were rather large (left: 4·5 × 3·3 cm.; right: 3·7 × 3 cm.) and showed an abundant fibrous stroma containing numerous follicular cysts measuring up to 0·4 cm. diam. A hæmorrhagic corpus luteum (2·3 × 1·3 cm.) with a lutein zone, 0·2 cm. broad, was present in the left ovary.

MICROSCOPIC EXAMINATION

The pituitary gland was treated in the same manner as in Case 1. Portions of the following tissues were embedded in paraffin: liver, both kidneys, spleen, suprarenal body, thymus, thyroid and parathyroid glands, carotid bodies, body of pancreas, both ovaries, upper lobe of left lung, left basal ganglia, right pectoral muscle, body of uterus, trigone of urinary bladder, and marrow from right femur. Portions of rib, great trochanter, and sternum were decalcified in Müller's fluid for three months followed by 0·5 per cent. nitric acid in 4 per cent. saline formaldehyde. The same stains were employed as in Case 1. Sections of the liver, both kidneys, spleen, pancreas, suprarenal body, right pectoral muscle, and left basal ganglia were cut on the freezing microtome and stained with Scharlach R and hæmatoxylin.

The pituitary gland.—Near the centre of the upper half of the anterior lobe is a sharply defined spherical adenoma measuring 1·5 × 1·2 mm. in the horizontal plane and about 2 mm. in the vertical plane (Fig. 4). It is not encapsulated but the surrounding acini are compressed. The cells are well preserved and are typical basophil cells of the same size and shape as those of the surrounding gland. In the margins of the upper and lower poles of the adenoma a few acidophil cells are mingled with the basophil, and the outline of the tumour is here rather poorly defined. The remainder of the anterior lobe presents no obvious abnormality. It is not possible, on inspection, to detect any disturbance in the relative proportions of the three types of cell present. The posterior lobe is intact and is relatively small. There are a few minute areas adjacent to the pars intermedia in which the tissue is occupied

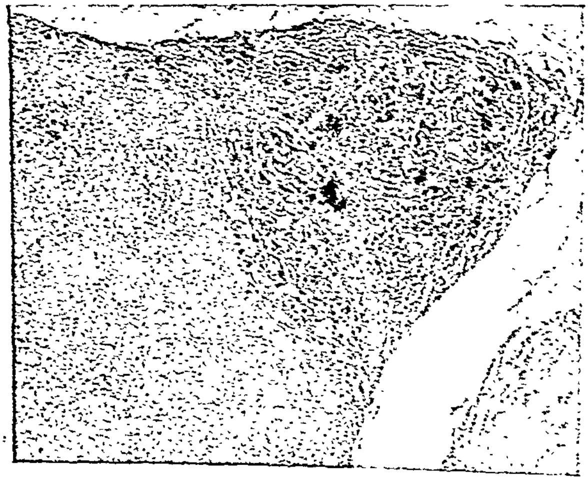

FIG. 3.—Basophil adenoma at antero-lateral border of anterior lobe. Acid-fuchsin aniline-blue (× 13).

by small groups of basophil cells. A somewhat larger group is present near the deep surface of the posterior lobe (Fig. 5); it is not, however, of abnormal dimensions.

The kidneys.—A moderate degree of ischæmic nephritis with none of the inflammatory changes typical of Bright's disease is present. In the lumina of some of the tubules and in the interstitial tissue of the cortex are rather abundant deposits of amorphous hæmatoxyphil material which blackens with the silver nitrate method of von Kossa and is negative to the Prussian blue test. These deposits are probably, therefore, of calcium.

The endocrine glands.—In the *suprarenal body* the normal pattern of cortex and medulla is preserved. The cortex is not hypertrophied. There is much lipoid in the zona fasciculata. One minute cortical adenoma is present in the capsule. In a section stained with acid-fuchsin aniline-blue, after mordanting with potassium bichromate, there is a very scanty amount of fuchsinophil material in the cytoplasm of a few of the cells in the innermost layer of the cortex. There is extensive post-mortem digestion, but no further change in the parenchyma of the *pancreas*. The islets show post-mortem degeneration but no fatty changes. The lobules of the *thyroid gland* contain many large, often very large, vesicles which contain colloid but very rarely show any flattening of their epithelial lining. Among these are numerous small vesicles which contain a little colloid, or are empty, or are filled with epithelial cells. There are a few areas of lymphocytic infiltration. The appearances are those of exceptionally active secretion and storage of colloid. The *thymus* consists of small, but definite, lobules of thymic reticulum with numerous focal areas of lymphoid infiltration, which form an interrupted cortex. There are many small Hassal bodies in the medulla. The *parathyroid glands* and *carotid bodies* appear normal. Both *ovaries* show corpora fibrosa and Graafian follicles in various stages of maturation. The corpus luteum in the left ovary contains red corpuscles and fibrin and has a deep, well-defined border of lutein tissue. A loose net of collagen fibres and fibroblasts occupies a narrow zone in the margin of the clot. The *endometrium* is deep. The tubules are large and slightly tortuous. In the outer three-quarters the stroma is rarefied and its spindle cells are slightly rounded.

The *bones* are normal in histological structure. Hæmopoietic marrow occupies about an equal area with adipose

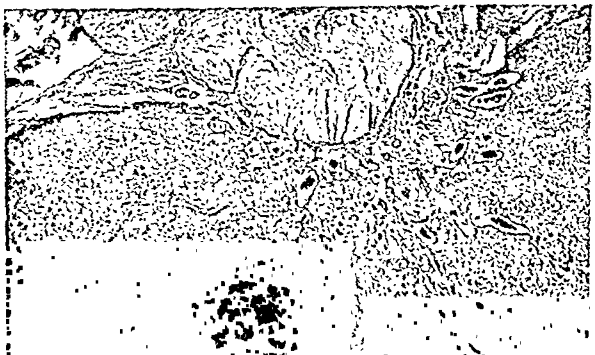

FIG. 4.—Basophil adenoma in anterior lobe. Note compression of surrounding acini. Acid-fuchsin aniline-blue (× 13).

in the centre of the shaft of the femur, but is in moderate excess in the rib and sternum. The hæmopoi
normal in character.

Discussion

Two cases have been described in which
adenoma of the pituitary gland was sus
necropsy on account of the physical appearan

subjects and the presence of a conspicuous degree of cardiovascular hypertrophy.

In the first case a full clinical investigation had caused attention to be centred upon the cardiovascular and renal systems. The possibility of a

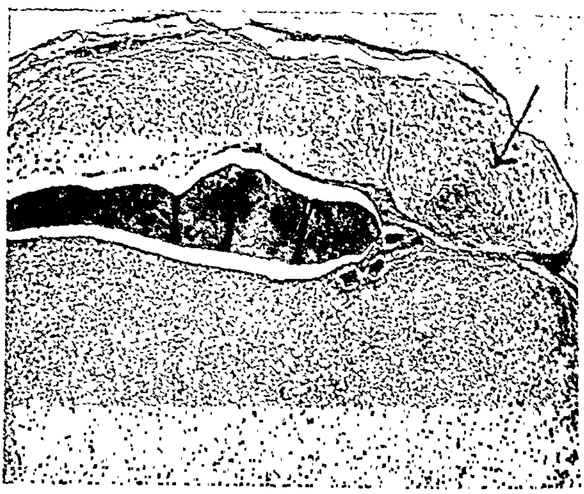

FIG. 5.—Arrow shows largest area of inversion of posterior lobe by basophil cells. Acid-fuchsin aniline-blue (× 13).

pituitary tumour had been considered at an early stage of the illness on account of the severe headache, obesity, and impotence, but was abandoned when the radiological examination proved to be negative. After that the case was regarded as one of essential hypertension. Finally, the finding of albuminuric retinitis suggested the presence of a malignant hypertension (nephritis repens), and this suspicion was later justified by the manner of his death. In retrospect several of the principal clinical features of Cushing's syndrome could be identified in this case: the obesity of peculiar distribution associated with
abdominal striæ, hypertension, plethor admission. The
rhages, and impaired sexual functi age.

In the first case cardiovascular hypertrophy and chronic Bright's disease formed the most conspicuous part of the pathological anatomy and were undoubtedly the cause of death. The second was a straightforward case of cerebral hæmorrhage secondary to cardiovascular hypertrophy. For a woman of such short stature the hypertrophy was very great. The renal changes here were of pure ischæmia—that is, they were secondary to the vascular degeneration present in the kidney and there was no trace of the histological characteristics of true Bright's disease.

In the pituitary gland alone of the endocrine organs was there an abnormality common to both cases. In the second case the thyroid gland showed an exceptional degree of activity, the appearances resembling those of the hypertrophy of puberty. In the 12 published cases accepted as examples of basophil adenoma the condition of the thyroid gland was described as "colloid goitre" in 1, "early colloid goitre" in 1, "moderately enlarged" in 1, and "slightly enlarged" in 2. In our second case also, the woman of 33, the thymus was sufficiently developed for the glandular tissue to be visible to the naked eye. No significance can, however, be attached to this, because a similar or greater development is found in a considerable proportion of women who have died between the ages of 25 and 35 from various causes. In the 12 accepted examples of basophilism there is only one record of a thymus which appears to have been of exceptional development. In a woman of 20 the gland weighed 24 g. (Teel, 1931). It is not stated whether it was entirely glandular but the microscopic description suggests that it was. Various proportions of glandular tissue are recognisable with the naked eye in the thymus in nearly half the necropsies upon women of 19 to 21. In a review of 80 deaths from various causes other than Graves's disease during these ages, only 3 glands were described as entirely glandular, and the weights were 8·3, 10·9, and 23 g. The latter gland occurred in a woman of 19 who died from broncho-pneumonia. An "almost completely glandular" thymus weighing 22 g. was found in a woman of 20, killed by an accident. From the available data, therefore, an entirely glandular thymus of 24 g. at the age of 20 would appear to be exceptional and possibly significant.

The rarity of enlargement of the thymus in basophilism is remarkable in view of the very similar clinical syndrome of Leyton, Turnbull, and Bratton (1931) and Kepler (Case 4, 1933). In this syndrome neoplasms of the thymus were associated with plethora, hirsuties, adiposity of similar distribution to that in basophilism, diabetes, hypertrophy of the suprarenal cortex, and hyperactivity of the thyroid gland, while serial microscopic section revealed no abnormality in the pituitary gland.[1] Cardiovascular hypertrophy was found at necropsy in one case and the blood pressure was abnormally high during life in another. The ribs were friable in Kepler's patient.

In both the cases here reported the suprarenal bodies were well within the limits of normal weight (Leyton, Turnbull, and Bratton, 1931). There were no cortical adenomata in the first case and a few pinhead adenomata only in the second. In three also of the verified examples of basophilism reported in the literature (Bauer, 1930, Bishop and Close, 1932, and Kepler, 1933, 1934) the suprarenal bodies were of normal size. It seems legitimate to assume from these five cases that the suprarenal cortex plays a secondary part in the syndrome. In both our second case and in Bauer's case the pituitary adenoma was very small. It might therefore be argued that cortical hypertrophy occurs only when the adenoma has attained a certain size. The adenomata, however, in our first case and in the Bishop-Close case were relatively large and the suprarenal bodies here too were of normal size.

In view of the recent, and apparently paradoxical, claim of Cushing (1932) that the basophil cells are closely linked with the gonadotropic hormone of the pituitary gland and that adenomata of these cells consequently lead to sexual dystrophy, it is noteworthy that in our first case the testicles showed active spermatogenesis in spite of the history of impotence, while in our second case there was no irregularity of menstruation and at necropsy the sexual organs were of full size and of normal histological appearance. Graafian follicles were present in both ovaries and a corpus luteum in one. This second case offers some analogy to Teel's case in which a small adenoma, 2·5 mm. diam., was found on serial section. Menstruation had been irregular, but a corpus luteum was present in one ovary. Both Teel's adenoma and that discovered in our second case were therefore relatively small, and it might be argued that they were too small to produce any gonadal disturbance. But in Bauer's case the adenoma was even smaller (0·9 × 0·5 mm.) and amenorrhœa was included among the typical features of the syndrome. Gonadal disturbance does not appear, therefore, to be correlated with the size of the adenoma.

From a study of the blood picture and tissues in Case 1 erythrocythæmia can certainly be excluded, whilst the tissues in Case 2 show no appreciable degree of erythrocythæmia. In neither of our two cases did the bones present any macroscopic or microscopic evidence of osteitis fibrosa or any other abnormality.

Our two cases, considered in conjunction with those reported elsewhere, suggest that the correlation between basophil adenoma, obesity, and persistent high blood pressure is very close. They show that the correlation, if it exists, is between basophil adenoma and high blood pressure as such, and not between basophil adenoma and chronic Bright's disease. This point is stressed because MacMahon, Close, and Hass (1934) have recently described the changes of malignant nephrosclerosis in two verified examples of basophil adenoma. Through the kindness of Drs. Close and Bishop one of us (D. S. R.) has been able to examine histological preparations of the kidney in the Guy's Hospital example. The similarity between this and the kidney in our first case is very striking. Further work is needed to show whether basophil adenomata can also be demonstrated in types of chronic Bright's disease with secondary cardiovascular hypertrophy other than malignant nephrosclerosis (nephritis repens, type 4), a form of nephritis in which the degree of cardiovascular hypertrophy is often maximal. Both Kraus (1928) and Berblinger (1932) claim that an increase in the number of basophil cells is demonstrable in a large percentage of all cases of hypertension. According to them the increase is diffuse and they do not describe discrete masses of these cells in either the anterior or the posterior lobes. They do not appear to have made any differential counts of the cells in the anterior lobe in support of their claims. The nature of the relation between the basophil cells and the cardiovascular system is as yet unknown.

---

[1] Serial sections of the pituitary gland in the two cases of Leyton, Turnbull, and Bratton were made after the original publication. (See Kepler, 1933, p. 103, and Cushing, 1933, p. 519.)

In recent papers Cushing (1933, 1934) suggests that basophilic invasion of the posterior lobe may be potent in producing the features of his syndrome as well as the clinical conditions of eclampsia and essential hypertension. He was led into putting forward this suggestion by finding, in addition to a basophil adenoma, an extensive infiltration of the posterior lobe with basophil cells in a fatal case of his syndrome. In neither of our two cases was the amount of such infiltration as great as is often found in normal subjects. Fig. 5 shows the largest area present—Case 2.

Summary

(1) The clinical and pathological features are described of two cases of basophil adenoma of the pituitary gland. (2) The syndrome described by Cushing as "pituitary basophilism" was imperfectly manifested in both examples, especially in Case 2. (3) The salient feature in both was cardiovascular hypertrophy. Obesity was present in both, but was of atypical distribution in Case 2. In the female there was moderate hypertrichosis of masculine distribution. (4) Bright's disease was the cause of death in Case 1, but in Case 2 cerebral hæmorrhage complicated essential hypertension and primary ischæmic nephritis of moderate degree. (5) In neither of our cases was there any abnormal invasion of the posterior lobe by basophil cells. (6) The association between basophil adenoma and cardiovascular hypertrophy is emphasised, but the nature of the association remains obscure.

Our best thanks are due to Prof. H. M. Turnbull for his help in preparing this paper, and to Drs. W. W. Woods and A. B. Bratton for the necropsy reports.

Bad Nauheim: Internisten Congress.—Over a hundred people took part in the Internisten Congress held recently in Bad Nauheim, among them being doctors from Spain, Sweden, Bulgaria, and Japan. The visitors were received by Dr. Diehl in the name of the Reichsstatthalter. The director of the Balneological Institute demonstrated some heart sound films, showing that by modern methods it is possible to find out changes of heart sounds much more exact than formerly, the changes being laid down in a curve, so that the improvement or deterioration in the course of a year can be observed. The guests also visited the William Kerckhoff Institute, where the director, Prof. Koch, explained to them the working methods employed for the investigation of cardiac disease. Entertainment at the Johannisberg concluded the visit.

SOME POINTS IN THE TREATMENT OF RHEUMATIC DISEASES*

By Charles W. Buckley, M.D., F.R.C.P. Lond.
PHYSICIAN TO THE DEVONSHIRE ROYAL HOSPITAL FOR RHEUMATIC DISEASES, BUXTON

The infective origin of rheumatic fever and rheumatoid arthritis is now generally admitted, but the precise mode in which the infective agent sets up the disease is believed to be much more complex than was supposed. While some strain of hæmolytic streptococcus probably plays an important part it seems probable that other organisms may be capable of producing a symptom complex clinically indistinguishable from that attributed to the streptococcus, or may be associated with it. Gibson and Thomson[1] after a searching investigation arrived at the following conclusions: "Acute rheumatism is due to some infective agent not yet defined, whose entry into the body may be facilitated by infection with hæmolytic streptococci. A possibility is that the late allergic manifestations of streptococcal infection may damage the tissues susceptible to rheumatic infection and facilitate generalisation of the specific agent." Continuing, they say: "Such a theory correlates (1) the close epidemiological association of the hæmolytic streptococci with acute rheumatism, and (2) the widespread distribution of hæmolytic streptococcal infection and the comparatively limited distribution of acute rheumatism."

These observations apply with equal appropriateness to rheumatoid arthritis which is undoubtedly due to some infective agent not yet precisely identified, whose entry into the joints may be rendered possible by allergic effects set up by a focus of infection elsewhere either by the same microbe or by others. In expressing this view I am not unaware of the work of Cecil, Nicholls, and Stainsby[2] among others who have isolated from the blood by culture a streptococcus, and claim to have set up arthritis by its inoculation into animals.

INFECTION AND HYPERSENSITIVENESS

In a large proportion of cases of rheumatoid arthritis a septic focus can be discovered. From such a focus absorption of toxic bacterial products goes on, and the toxins gradually sensitise the tissues until a point is reached at which rheumatic symptoms develop—whether by reason of the further action of the toxins themselves or by actual bacterial invasion has yet to be demonstrated. It follows that the septic focus should be removed at as early a stage as possible if it can be identified, but never in such a way as to flood the system with toxins; for an acute outbreak of arthritic symptoms has not infrequently been known to follow wholesale extraction of teeth or tonsillectomy. A course of desensitising treatment by means of minute doses of a suitable vaccine may serve to avert such a catastrophe.

In such septic foci usually several different microbes are found, and even though it may some day be proved that certain types of arthritis are invariably associated with the presence of one definite organism, it is probable that the toxins of some prepare the way for others. Swift, Derrick, and Hitchcock,[3] who have done much important work on this subject, state that inoculation with non-hæmolytic streptococci produces a hyperergic condition and increased susceptibility, not only to the same strain but also, to more distantly related strains; possibly, one may add, to entirely different microbes also.

---

* Abstract of a lecture given before the Furness Division of the British Medical Association.

The view has long been held on the continent that there is a type of rheumatoid arthritis which is tuberculous in origin but much of the evidence has been unconvincing. Positive reactions to such tests as those of von Pirquet and Mantoux may easily be due to latent tuberculous foci in glands or elsewhere, and the isolation of tubercle bacilli from the blood in cases of acute polyarthritis by the method of Reitter and Lowenstein has generally been unsuccessful in other hands. Recently, however, some cases have been published in which affected joints diagnosed clinically as rheumatoid arthritis have been opened and synovectomy has been performed, histological examination has demonstrated tuberculosis, and culture has in some cases been successful.[4] In two cases of my own of chronic polyarthritis I have found tubercle bacilli in the effusion from the knee-joints. It is stated that in some cases filter-passing types of the bacillus of Koch of low virulence have been isolated, which on inoculation into guinea-pigs have set up a tuberculous adenitis but not a general tuberculosis.

It cannot be denied that the constitutional type, and the symptoms apart from the actual arthritis, in many cases are similar to tuberculosis. There is also the possibility that a chronic tuberculous focus in the glands or elsewhere can sensitise the tissues to and thus favour infection by streptococci, but it seems more probable that the sensitisation of the tissues is set up in the first case by streptococcal infection and infection by tubercle follows.

The sensitisation of the tissues brought about by the absorption of toxins from a focus elsewhere in the body is of great importance, inducing an allergic condition. Rich [5] defines allergy as that state of specific hypersensitivity which develops as a result of the entrance of foreign protein into the tissues—with local tissue damage wherever the foreign protein or a fraction (haptene) lodges in the sensitised tissue, and constitutional symptoms when the protein to which the body is sensitised enters the blood stream. Some writers do not draw a distinction between allergy and anaphylaxis, and the whole problem is difficult and confusing; but while sensitisation is generally believed to be a stage in the development of immunity, Rich has shown that it is possible to separate the two processes. Acquired immunity is an ability to inhibit the growth and invasion of bacteria whose toxins have been the sensitising protein, and to neutralise these toxins. There may be such a degree of immunity as can cope with a small invasion, but an extensive extraction of teeth or a tonsillectomy may release more of the specific toxin or organism than can be dealt with, or sensitiveness may be heightened by injudicious vaccine therapy or otherwise, and fresh invasion takes place from the original focus or from secondary foci.

Hypersusceptibility may of course result from other causes—climatic conditions to which the individual is ill-adapted, by no means the same for everyone; malnutrition from lack of suitable food, under which heading may be included vitamin deficiencies; overwork or severe nervous or emotional strain, such, for example, as often results from long nursing of a sick relative; shock; endocrine deficiency; bad hygienic conditions at home or in the workshop; and many others. All these conditions may be regarded as sensitising factors in the widest sense.

USE OF VACCINES

The specific treatment of the bacterial factor has been the object of much research both at the bedside and in the laboratory. Treatment by vaccines has had a great vogue, and is based on the assumption that by the administration of a suspension of a microbe believed to cause the disease we might raise the resistance of the body and thus enable it to overcome the infection. While overwhelming clinical evidence of the value of this procedure in securing prophylaxis is forthcoming no such claim can be advanced for it as a method of treatment, and as Topley [6] says, "the practice of vaccine therapy rests on a very inadequate basis of experimental evidence." As a method of treatment it has been more extensively used in chronic rheumatic disease than in any others, with the exception perhaps of local staphylococcal lesions where the conditions are different. To the ordinary observer it seems illogical, when the system is already invaded by some microbe, and has presumably mustered all its defensive forces to combat the invasion of the bacteria and to neutralise their toxins, to inject further doses of the same toxins. And yet good results have undoubtedly followed such treatment in some cases, though I fear more cripples than cures have resulted from indiscriminate and injudicious vaccine therapy. To what, then, are the successes to be attributed? It may be that the amount of toxin or bacteria absorbed from the septic focus is insufficient to rouse the whole of the defensive forces of the body, and the vaccine produces a further or more powerful stimulation; but, on the other hand, the risk of sensitising the tissues further is a very grave one, and in consequence dosage must be extremely small to begin with if it is thought desirable to use such treatment. A vaccine administered in very small doses at suitable intervals, or in such a way as to secure very slow absorption as by the intradermal method, appears to act not by stimulating antibody formation but by inducing desensitisation.

An example of this method of desensitisation is found in the prophylaxis and treatment of hay-fever and asthma—typical allergic states—by the injection of minute doses of the protein or other substance to which the victim is susceptible. It does not appear essential for desensitisation that the vaccine should be autogenous, and as proof is yet lacking as to the exact nature of the infecting organism it seems hardly justifiable to speak of an autogenous vaccine if by that it is claimed to be a vaccine of the infecting microbe. All that can be said is that it contains some of the microbes from the patient's own focus, and may therefore be more effective in desensitisation in the particular case.

The intradermal use of vaccines for desensitisation has been tried, particularly in France, with some promising results. The method has three features—slow absorption of minute doses of a mixed antigen; the stimulation of the deeper layers of the dermis to produce antibodies, which some regard as a point of importance; and polyvalency with the inclusion of tuberculin which is regarded as a universal non-specific antigen—and this may be the most important feature. The possibility of a tuberculous basis in some forms of arthritis to which reference has already been made receives support from the good effects which I have known to follow treatment by this method. It is necessary to study the effects carefully, increasing the intervals gradually, especially if there is reason to suspect the existence of tuberculous foci, active or latent, in the system. If there is no sign of benefit after three or four inoculations it is better to try some other method, but I have noted in several cases marked improvement manifested by a rise in the sedimentation-rate as well as in the general symptoms. A course of ten or fifteen inoculations seems to be the best, followed, if necessary, by chrysotherapy.

This method of using vaccines as desensitising agents has the advantage of being reasonably free from risk, but none the less requires care, and it is desirable that a chart of the temperature should be kept and the character of any reaction noted carefully upon it; with such precautions the dose may steadily be increased, but any sign of increasing reaction without a proportionately increased dose calls for a temporary cessation of the treatment or the trial of some other method. In my opinion, the success which is claimed for a vaccine which is supplied commercially, and has attained considerable popularity for the undoubtedly good effects which have resulted in many cases, is due to its action as a desensitising agent.

In regard to the intradermal use of a vaccine, the observation of Auer [7] is of interest; he found that injury to the skin of a sensitised animal when antigen was in the circulation might produce a local reaction due to the actual excretion of sensitinogen into the injured area. Jenkins [8] has suggested that from this observation it may be inferred that once a joint is damaged a more or less continuous irritation is set up by the antigen in the blood, and a vicious circle is started which can only be broken by the removal or neutralisation of the circulating antigen.

The use of vaccines in the ordinary way is believed by some to be simply a form of protein shock therapy. However produced, so-called protein or peptone shock sets up an anaphylactoid reaction differing in some details from true anaphylactic shock; but the resemblance to the shock effect produced by antigen-antibody reaction is striking. This is due to the liberation of a histamine-like substance, and the influence of histamine in the treatment of arthritis is receiving considerable attention. As a local method it has proved of definite value.

BACILLARY DYSENTERY OF THE NEWCASTLE TYPE

BY HENRY WHITEHEAD, M.D. Manch., D.P.H.
MEDICAL OFFICER OF HEALTH, WIGAN

With a Note on the Bacteriology

BY W. M. SCOTT, M.D. Edin.
A MEDICAL OFFICER OF THE MINISTRY OF HEALTH

ON Jan. 15th, 1934, Dr. R. J. Ormsby, medical officer of health for Standish, called at my office and asked me if I would admit to the Wigan Infectious Diseases Hospital two cases of probable food-poisoning. He informed me that four people had been affected in one house in his district, a mother and her three children. The two children referred by Dr. Ormsby for admission had partaken of corned beef none of which was left for examination. The mother and the other child had not partaken of it. This third child, a boy, J. S., aged 12, had been sent to the Wigan Infirmary with marked cerebral symptoms *in addition to frequent vomiting*, abdominal pain and diarrhœa. He had a history of having fallen on his head a week before and, as the cerebral symptoms pointed to possible compression, he was trephined. He died on Jan. 15th, and post mortem marked inflammation of the intestinal tract was found. I advised Dr. Ormsby to call at the local infirmary and ask Dr. W. E. Cooke, the pathologist to this institution, if he would kindly forward to Dr. W. M. Scott, of the Ministry of Health, specimens of liver, kidney, spleen, stomach and intestines from the case according to the recommendation of the Ministry of Health in cases of possible food-poisoning. This material was sent as requested.

The other two children were admitted to the Wigan Infectious Diseases Hospital on Jan. 15th, 1934. The boy, F. S., aged 8, was extremely ill on admission with very frequent vomiting, abdominal pain, diarrhœa and symptons of cerebral irritation. His temperature rose to 103° F. on the second day and there was some delirium and violent headache. His colour was poor and his pulse very weak, with sighing respiration. He still complained of severe abdominal pain and there was much abdominal tenderness and rigidity. The vomit was very offensive and the stools, green and very foul smelling, showed occasionally mucus with traces of blood.

The other child, a sister, E. S., aged 11, was not so acutely ill on admission but had had very similar symptoms before that. She complained of severe headache but the vomiting and diarrhœa had subsided; there was some mucus in her stools. She made a rapid recovery.

The treatment was symptomatic together with rectal salines and glucose. Six days after admission the boy, F. S., had completely recovered. Specimens of his vomit and fæces were sent to Dr. Scott and specimens of his blood and that of his sister a fortnight later for agglutinin tests.

There is no evidence that any particular article of food conveyed the disease; no other similar cases are known to have occurred in the neighbourhood One may hazard the guess that the source of infection of this family may have been an undiscovered carrier.

Note on the Bacteriology. (*By* DR. SCOTT.)

The colon of J. S. received on Jan. 18th showed definite congestion with minute hæmorrhages in the mucosa.

MacConkey plates inoculated with scrapings from the mucous surface yielded only one non-lactose-fermenting colony (among many typical *coli* colonies). With the fæces from F. S., however, MacConkey plates were obtained showing numerous non-lactose-fermenting colonies. The two strains thus isolated, J. S. and F. S., behaved exactly alike in culture; they were non-motile, produced no indole and fermented dextrose and dulcitol but not lactose, sucrose or mannitol. The dextrose fermentation was evident after 24 hours but the dulcitol not till after five days at 37° C. With both "sugars" a small bubble of gas was produced as well as acid. Agglutination tests were negative with sera of the salmonella group and of the Flexner and Sonne dysentery types, but were positive to full titre (1600) with serum prepared with a strain of the Newcastle bacillus described by Clayton and Warren,[1] as well as with sera prepared with strains, regarded as serologically identical, isolated (1) by Downie and Wade [2] near Manchester,

(2) by Young[2] in Nigeria, and (3) by Boyd[3] as type 88, in India. The last-mentioned serum (Boyd 88) (titre 3000) was completely robbed of agglutinin for its homologue, as well as for Newcastle, Manchester and Nigeria strains, by absorption with cultures J. S. and F. S. Cross-absorption was not done, but there seems no reason to doubt that these two strains from Wigan belong to the species *Bact. dysenteriæ* (Newcastle). It is of interest that the Wigan strains are the first, so far as published records go, to be found in cultural agreement with the original strains of Clayton and Warren. The strains described by Downie and Wade were mannitol-fermenters, that by Young was originally motile, though it lost this character in subculture, while none of the strains of Boyd's type 88 (all mannitol-fermenters) produced gas with any "sugar."

Major Boyd, R.A.M.C., reports (personal communication) that his type 88 is responsible for quite a large proportion of cases of bacillary dysentery in India, and I have myself found to be serologically identical with it, and with the Newcastle strain, some 12 strains isolated in Waziristan by Capt. G. T. L. Archer, R.A.M.C., and brought to me by him last February. It is evident that the Newcastle bacillus is widespread in distribution and the cause of typical and not seldom fatal dysentery. Its identification in practice is most easily and rapidly achieved by direct macroscopic agglutination of a portion of a colony from the primary plate, inoculated with dysenteric mucus, in a drop of the specific serum, diluted, say, 1 in 50 with saline. The other dysentery bacilli, Shiga, Flexner and Sonne, will emulsify in such a drop without clumping, while bacilli from a colony of the Newcastle species will immediately run into dense clumps visible to the naked eye (but preferably inspected with a hand lens). In other specific agglutinating sera (Shiga, Flexner, Sonne) similarly diluted, the Newcastle colony will give perfect emulsions. Culturally the species is variable, as stated above, but the absence of indole-formation and the (slow) fermentation of dulcitol appear to be constant characters of differential value. Retrospectively, the diagnosis may be made by Widal tests of the convalescent serum with suitable suspensions of the Newcastle bacillus (preferably 24-hour broth cultures killed and preserved for storage by chloroform). The tests should be made in the usual way with serial dilutions of the serum in the water-bath at 50° C. for four hours and titres as high as 640 have been recorded (Downie and Wade[2]). In the case of the patients J. S. and E. S. of the Wigan outbreak above described, the titre for an emulsion of the Wigan strain reached 320 and 160 respectively, the blood having been obtained 14 days after onset of the disease. With the various Flexner types and with the Sonne bacillus, J. S. and E. S. convalescent sera gave practically no agglutination (negative at 1 in 20). The Wigan emulsion tested with "normal" human sera (Wassermann specimens), as controls, gave completely negative results with five out of six specimens: the sixth gave fine clumps up to 1 in 40 dilution, but not higher. Widal tests in Newcastle infections are, therefore, closely comparable in titre level to those in Sonne infections and are equally useful in epidemiological investigations.

TREATMENT OF BRONCHIAL ASTHMA

BY DORSAL PERI-SYMPATHETIC INJECTION OF ABSOLUTE ALCOHOL

By G. L. L. Levin, M.B. Lond.,

HON. MEDICAL OFFICER, NATIONAL INSTITUTE FOR THE BLIND, LONDON

Technique.—The patient is seated leaning forwards, the hands resting on the knees; the spine is arched backwards, and the tips of the shoulders are drawn in so as to allow the maximum retraction of the scapulæ. A point is selected 4 cm. away fom the spine, preferably in the third, fourth, fifth, or sixth intercostal spaces. A few drops of novocaine are injected intradermally so as to raise a weal; the needle carrying the absolute alcohol is introduced perpendicularly just above the space to be injected down to the inferior margin of the rib; as soon as the rib is felt the needle is directed slightly downwards and 45° forwards and inwards to the depth of about 2 cm. away from the lower margin of the rib. The point of the needle is now between the external and internal intercostal muscles. The needle is pushed slightly further inwards towards the spine and about 2·5 c.cm. of absolute alcohol are slowly injected, slightly altering the position of the needle for each spurt. Usually a sharp pain is felt in two or three interspaces immediately below the site of injection. Two or three intercostal nerves can be dealt with at the same sitting.

The only possible complication is injury to the pleura; the entry of the needle into the pleural cavity can be, however, easily observed by the thick velvety feel of the pleura and by a hissing noise due to entry of air (it is preferable therefore to introduce the needle alone without the syringe). In doubtful cases the needle should be connected with a manometer, and the presence or absence of respiratory excursions of Hg will show whether the needle is, or is not, in the pleural cavity.

Similar results may be directly obtained by dorsal sympathectomy. Leriche in Nelson's "Loose Leaf Living Surgery" (Vol. IV.) describes the following method of the latter:—

> A vertical incision is made one inch lateral to the spine and two inches above and below the selected intercostal space; the muscles are split and retracted as far as the articular processes inwardly and the costal tubercles outwardly. The transverse process is divided close to its base, and the intercostal nerve is exposed lying on the endothoracic fascia covering the pleura—below the corresponding vein and artery. The nerve is hooked forwards, and the rami are recognised as tense threads on the inferior aspect of the nerve; they are sectioned, and the wound closed.

Leriche reports a number of successes by this method.

Adson advocates very much the same line of approach to the second intercostal space. His further steps comprise resection of the second rib, division of the sympathetc trunk below the second thoracic ganglion, followed by total extirpation of the lowest cervical and the first and second thoracic ganglia. In this way all the fibres travelling to the pulmonary plexus via the cervical sympathetic are completely divided. The operation appears rather severe, and too widespread in its effects; all the other thoracic organs—the heart and the œsophagus—are largely deprived of their sympathetic supply; branches to the brachial plexus are also completely interrupted.

It is obvious, however, that injection of absolute alcohol into the bronchial sympathetic nerves is in many respects more advantageous than an operation. Injection can be repeated many times without undue disturbance to the patient; total destruction of sympathetic rami is unnecessary, partial destruction being sufficient to alter the nerve balance in favour of relaxation; and, finally, advanced asthmatics are hardly fit subjects for operative interference.

Clinical Observations.—So far, 16 patients have been treated by the absolute alcohol method, the majority of them being so-called incurables. In 10 cases there was complete relief after four to eight injections; in one case there was sufficient improvement after two injections for the patient to discontinue treatment; in 3 cases there was a very considerable improvement after two or three injections; in 2 cases the improvement was only slight. The following are brief case-histories:—

CASE 1.—Mr. A., aged 30. Severe asthma of four years' standing. No relief from adrenaline. No improvement after a course of autogenous vaccine prepared from sputum. Signs of heart failure. Life unbearable. Injection of absolute alcohol in the third and fourth rami on each side. Great improvement after the second injection. Complete disappearance of asthma after the fourth injection. No return of asthma for the last three years.

CASE 2.—Miss B., aged 22. Bronchial asthma since age of 6; totally incapacitated for pleasure or study. Only temporary relief after injection of morphia gr. ¼. Heavy nasal catarrh. Improvement after autogenous vaccine and peptone—return of asthmatic attacks with vengeance. Four absolute alcohol injections into the fourth and sixth left interspaces and the fifth and sixth right interspaces. Pleuritic pain after the first two injections necessitating rest in bed. Complete cure; no recurrence for the last two years.

CASE 3.—Mr. C., manual worker, aged 48. Since age of 12 subject to bronchial asthma; never entirely free; incapacitated for work four months in the year. Treated by alcohol injections, five in all. Breathing has been perfectly free for the last 20 months.

CASE 4.—Mr. D., aged 31. Severe daily attacks of bronchial asthma for the last six years; unable to sleep for a period longer than two hours at most. Four absolute alcohol injections into the third and eighth left interspaces, and the fifth and sixth right interspaces. Considerable improvement; the attacks now occur only in a mild form and, on the average, once in ten days.

Summary.—(1) The bronchial rami contained in the sympathetic dorsal fibres are comparatively superficial at one part of their long course—namely, at the point where they join the corresponding intercostal nerves. At this point they are open to attack either by knife or by absolute alcohol injection. (2) Clinical results of alcohol treatment are so far very encouraging, cure resulting in three-quarters of the cases. (3) The cases most suitable are those of long-standing inveterate asthma.

SECONDARY CARCINOMA OF THE MYOCARDIUM

BY E. MILFORD WARD, M.B. Lond.
SENIOR RESIDENT MEDICAL OFFICER, CITY ISOLATION HOSPITAL AND SANATORIUM, LEICESTER; LATE SENIOR HOUSE PHYSICIAN, ROYAL INFIRMARY, LEICESTER

CARCINOMA with secondary involvement of the myocardium is occasionally found post mortem, but is rarely recognised during life; indeed Goldstein,[1] who reviews 100 cases of primary tumour of the heart and reports nine cases of secondary growth, says that the diagnosis is never made until autopsy. Hamilton,[2] who found secondary involvement of the heart in 0·28 per cent. of cases of carcinoma, states that the primary lesion is most often in the thorax. Welch[3] reports a case in which it was in the prostate. He gives figures from the pathological institute of the University of Berlin showing that in 6655 autopsies there were 15 cases of carcinoma of the heart (0·22 per cent.). The lesion was always secondary, and the primary was in various organs. Boyd,[4] who also mentions the extreme rarity of myocardial secondaries, says that malignant melanomata are the most common growths to give rise to deposits of this kind.

In 1281 autopsies at the Leicester Royal Infirmary there were 103 cases of carcinoma, 32 of sarcoma, and 9 other malignant growths. Among these there were four cases in which there was growth in the myocardium, two of carcinoma (1·9 per cent.), and two of sarcoma (6·2 per cent.). Including all autopsies, carcinoma of the myocardium was found in 0·3 per cent. A primary sarcoma of the mediastinum gave rise to a mass in the pericardium which ulcerated into the left ventricle; a small round-cell sarcoma of the retroperitoneal tissues was associated with nodules in the heart muscle; a primary carcinoma of the left suprarenal was followed by pericarditis due to deposits in the pericardium. The fourth case is now reported.

Specimen showing secondary deposits of carcinoma in the myocardium, the primary growth being at the pylorus.

History—A. B., aged 42, a grocer's assistant, was admitted to hospital on Oct. 12th, 1931, complaining of a pain in the back. He had first complained six months before, but no abnormal physical signs were elicited and a provisional diagnosis of sciatica was made. A course of radiant heat baths was advised and the patient experienced relief for a short time. When the pain recurred it was referred to the middle of the back. It was gnawing in character, present all the time, but worse at night so that sleep was disturbed. Although the pain was not related to food, the appetite was poor. There was neither nausea nor vomiting. The bowels had been loose but on admission to hospital were normal. There had been no melæna;

much weight had been lost. Two months before admission to hospital numerous small tumours had appeared in the skin of the abdomen and thorax.

Examination.—The patient looked much older than his years, and was very emaciated. The tongue was dry and swollen, the gums edentulous. No abnormal physical signs were found in the lungs. The apex-beat was not displaced, the heart sounds were regular and of good quality, and there were no cardiac murmurs. The skin of the abdomen was studded with small tumours each of approximately half an inch diameter. These were freely movable in the skin and were hard. A tumour was visible in the left hypochondrium, appearing from beneath the costal margin, and passing towards and beyond the umbilicus. It moved on respiration. It was hard and tender, the edges were ill-defined, and no notch could be felt in the anterior border. The tumour could not be palpated in the loin and the percussion note over it was resonant. The liver was enlarged two fingers-breadth below the costal margin and its surface was roughened.

Pathological investigations.—The blood count on admission was: red blood-cells, 3,668,000 per c.mm.; hæmoglobin, 50 per cent.; colour-index, 0·68. The red cells showed anisocytosis, poikilocytosis, and polychromasia. No normoblasts were seen. White cells numbered 22,812 per c.mm. (polymorphonuclears, 94 per cent.). A fractional test-meal showed no free HCl throughout; a trace of lactic acid was present. Radiography of the alimentary tract after an opaque meal revealed considerable deformity of the pyloric end of the stomach, suggesting pressure from without the stomach rather than intrinsic disease of its wall, secondary involvement of the latter not being excluded. The gastric emptying time was not impaired, and there was no obstruction in the duodenum. A lesion of the pancreas was suggested. A tumour was excised from the abdominal wall and sectioned; it showed a typical spheroidal-cell carcinoma.

Subsequent progress.—Five days after admission the patient vomited large quantities of dark fluid resembling changed blood. The pulse-rate rose from 100 to 120, the cardiac rhythm remained regular. Death took place on Oct. 25th. Permission to examine the abdomen only was obtained.

Post-mortem report.—The peritoneum was studded with small nodules similar to those in the skin. A small amount of free pus was found round the pylorus. The liver weighed 74 oz., there was extensive perihepatitis, and secondary nodules were present throughout. A large ulcer was found at the entrance of the pylorus with hard, raised edges. This ulcer was adherent to the pancreas which was infiltrated with growth. The mass made by the pancreas and the enlarged posterior abdominal glands comprised the tumour which could be palpated per abdomen. Nodules of growth were found in both kidneys and suprarenal glands. The heart was removed through the diaphragm. The myocardium was studded with small nodules of growth, nodules projected into both auricles (see Figure). Sections of all secondary deposits and the pyloric ulcer were examined, and all showed a similar type of growth. It was a spheroidal-cell carcinoma.

Post-mortem diagnosis: General carcinomatosis secondary to carcinoma of the pylorus.

It will be noticed that there were no symptoms of cardiac damage (save a moderate degree of tachycardia after hæmatemesis) noticed during life. This appears to be usual. The case presented some difficulty in diagnosis, especially as the tumour palpable in the left hypochondrium somewhat resembled an enlarged spleen.

My thanks are due to Dr. J. V. C. Braithwaite for permission to publish this case, and to Dr. W. W. Mackarell for allowing me access to the post-mortem register at the infirmary.

ANTIHÆMOLYSIN TITRES IN CHRONIC RHEUMATIC AND ALLIED DISEASES

By G. J. Griffiths, B.Sc., M.B. Lond.

PATHOLOGIST AND RESEARCH SCHOLAR IN RHEUMATIC AND ALLIED DISEASES AT THE DEVONSHIRE ROYAL HOSPITAL, BUXTON

In 1932 Todd[1] showed that after infection with hæmolytic streptococci the antihæmolysin titre of the serum materially increases and that this increment is found, almost without exception, after an attack of acute rheumatism.

In 1932, following the examination by Dr. Todd of ten samples of serum obtained in this hospital from cases of subacute rheumatism, which gave a high proportion of high antihæmolysin titres, it was decided to investigate a larger series of cases of the various forms of rheumatic diseases admitted to the Devonshire Royal Hospital.

The *methods* used were essentially those given by Todd[2] and Todd and Hewitt,[3] except that the medium used for the preparation of the streptococcal hæmolysin was prepared with bullock flesh instead of horse flesh and the organisms were grown at a very reduced pressure, usually about 30 mm. Hg.

When the cultures were grown at atmospheric pressure it was found that the hæmolytic activity of the filtrate varied considerably. After cultivation at reduced pressure and allowing a longer period of contact during the reduction by the hydrosulphite, a hæmolysin of fairly constant strength was obtained. Half a cubic centimetre of a 5 per cent. suspension of human red blood-cells was completely hæmolysed by 0·05–0·1 c.cm. of the hæmolysin preparation. The hæmolytic broth was stored in vacuo in an ice box.

In the final determination of the antihæmolysin titre of the serum, the minimum hæmolytic dose (M.H.D.) of the hæmolysin was checked against a standard antihæmolysin kindly supplied by Dr. Todd and the results were expressed as antihæmolytic units, one unit being capable of completely neutralising 2½ M.H.D. of hæmolysin.

The results of the examination of 224 cases of rheumatic and allied diseases are shown in the accompanying Table, in which the results are expressed as percentages showing antihæmolytic titres above the normal, the maximum for which is taken as 50 units. This is the highest value obtained in a series of apparently healthy persons giving no history of recent streptococcal infection or sore-throat and agrees with one exception, with the normal values obtained by Todd.[1] [4]

Antihæmolysin Titres

Disease.	Cases.	Percentage. Abnormal (i.e., titre> 50 units).
A. Subacute rheumatism	64	83
B. Infective arthritis	95	59
C. Spondylitis ankylopoietica	11	64
D Spondylitis osteo-arthritica	6	27
E. Osteo-arthritis	6	Nil.
F. Fibrositis	27	52
G. Sciatica	12	(1) 42 (2) 22
H. Paget's disease	3	Nil.
I. Rheumatic fever (after Todd): quiescent	25	24
active	23	100

The values for sciatica are placed under two separate headings: the first, 42 per cent., includes three patients who were subject to frequent sore-throats; the second, 22 per cent., excludes these three patients.

The percentage of cases of subacute rheumatism giving a high titre approximates to that found by Todd in the active acute type and tends to confirm the close relationship that has been assumed to exist between these two types of rheumatic diseases. It will also be seen that the other forms of rheumatic and allied diseases can be divided into two groups.

(1) Rheumatoid arthritis and spondylitis ankylopoietica, having a definitely high percentage of abnormally high values, and which are regarded by many authorities as infective in origin.

(2) Osteo-arthritis and spondylitis osteo-arthritica, non-infective in origin, and giving but few high antihæmolysin titres.

The relatively high proportion of abnormal values in the fibrositis group is very suggestive of an infective factor in some cases, a conclusion also reached by Race [4] from a consideration of the suspension stability results. In the sciatica group, after the exclusion of cases with a history of recurrent sore-throat, the abnormal titres are few, and it is possible that some of these may be due to the presence of an infective fibrositis producing trunk sciatic symptoms. In the three cases of osteitis deformans (Paget's disease) all the results were normal.

Whilst the results given above cannot be regarded as proof of a cause-and-effect relationship between hæmolytic streptococci and rheumatic disease they do suggest that a hæmolytic streptococcal infection cannot be ignored. Other methods of investigation, such as skin reactions and agglutination tests, have also yielded results suggestive of an association of hæmolytic streptococci and rheumatic disease, but their significance when analysed by statistical methods is comparatively low compared with the antihæmolysin titres.

It might be objected that the antihæmolysin titres as determined by the process employed may be vitiated to some extent by the presence of a hæmolytic infection of non-streptococcal origin. Todd [1] examined numerous antitoxic and antibacterial sera, one of which was prepared from *Bacillus welchii*, an organism producing a strong exohæmolysin, and found all to have antihæmolysin titres not exceeding 50 units. Several hæmolytic strains of organisms have been examined in the Devonshire Hospital, and it was found that although streptococcal antihæmolysin serum could neutralise the hæmolysin produced by certain strains of staphylococci, *Streptococcus viridans*, or pneumococci, the hæmolytic property of such organisms is neutralised by such a small amount of streptococcal antihæmolysin as to suggest that any errors that may be produced by such infections are negligible in extent. Cowan [5] was able to produce pneumococcal antihæmolysin in rabbits, but the titre of the serum at its maximum was only approximately 800 M.H.D. as compared with 50,000 M.H.D. in Todd's streptococcal antihæmolytic serum, a ratio of only 1·6 : 100. *B. welchii* and certain strains of *B. coli* produce a potent exohæmolysin, but this is not neutralised by the streptococcal antihæmolytic serum and consequently does not affect the results.

Streptococcal antihæmolysin is not specific in its action, but the other hæmolytic organisms that might affect its determination are so weak in their hæmolysin production that in practice they can safely be ignored.

I wish to express my indebtedness to Mr. J. Race, F.I.C., biochemist to the Devonshire Royal Hospital, for his valuable help, criticism, and useful suggestions, which has made possible the surmounting of many difficulties in the investigations; also I thank Dr. C. W. Buckley, chairman of the research committee, for his interest and encouragement, and Miss M. Harrison, my assistant, for her technical help.

AN EXPLOSIVE ERUCTATION

By Terence East, D.M. Oxon., F.R.C.P. Lond.,
PHYSICIAN TO KING'S COLLEGE HOSPITAL AND TO THE WOOLWICH MEMORIAL HOSPITAL

> "Behold the stomach: crammed from every dish,
> The tomb of boiled and roast and flesh and fish.
> Where bile and wind, and phlegm and acid jar,
> And all the man is one intestine War!"

No doubt Pope meant these lines to refer to the effects of gluttony. But quite apart from this, organic disease of the pylorus may bring about a similar state of affairs and occasion the following remarkable and unusual mishap.

The patient was a middle-aged man, rather thin and pale. He said that for a number of years he had suffered at times from pain in the region of the stomach after food. Recently vomiting had troubled him. This took place at irregular intervals, the amount being copious. On going into details he remembered bringing up material that he had eaten many hours before. The vomit was offensive as a rule. He also was prone to violent and foul-smelling eructations. But what really distressed him more than anything else was the following startling occurrence.

One evening he had taken his wife to the cinema. There, in the darkness, feeling inclined to smoke, he had taken out a cigarette, and put it between his lips; he struck a match, bringing it up in his cupped fingers. Just at that moment a violent eructation occurred. To his alarm and astonishment, and of those seated near him, there was a flash and a sharp explosion; the cigarette was blown from his lips away across several rows of seats; his moustache was singed, and his lips and fingers burnt. In pain and confusion he had hurriedly to leave the cinema. The astonishment of the neighbours at this "fiery exhalation" can well be imagined.

The diagnosis of pyloric obstruction was fairly clear. Gastric peristalsis was easily seen. The barium meal showed the usual prolonged delay in the stomach. The gastric contents were copious, with yeast cells, sarcinæ, and lactic acid. No doubt the gas from the stomach mingled with the air in the mouth and cupped hands in just the right proportions, the cavities forming an explosion chamber, which required only a naked flame to produce this unpleasant occurrence. At laparotomy a cicatrised ulcer was found at the pylorus.

A few cases similar to this are on record. Beatson [1] mentioned a man whose breath caught fire one night when he was blowing out a match which he had struck to see the time. For some time past the foul odour of his breath had been noted. McNaught [2] described how a man eructated when blowing out a match, which he had struck in the night in order to look at his watch. His breath caught fire and his moustache was burned. In this case the gas from the stomach was analysed, and found to contain CO_2, 56 per cent.; H, 28 per cent.; CH_4, 6·8 per cent.; air, 9·2 per cent. He quoted several cases in the German literature where analysis of the stomach gases showed much the same composition. Another case recorded by Martin [3] suffered from foul eructations, smelling like rotten eggs. When lighting his pipe two hours after breakfast he belched, and there was a sharp explosion, which singed his beard and eyebrows.

No doubt these were all cases of pyloric stenosis. McNaught's patient improved with gastric lavage. The inflammable gases appear to be CH_4, hydrogen, and H_2S.

A gastroenterostomy was done successfully on the patient here described. There was the usual rapid increase in weight and return of well-being, now that his stomach, where, to quote the words of Jenner, "Sits enthroned the grand monarch of the constitution," was once more at peace.

REVIEWS AND NOTICES OF BOOKS

The Social Survey of Merseyside

Edited by D. CARADOG JONES, M.A. (University Press of Liverpool). London: Hodder and Stoughton, Ltd. 1934. Vol. I., pp. 328, 15s.; Vol. II., pp. 413, 21s.; Vol. III., pp. 560, 25s. Set of three volumes, 45s.

THIS survey, made mainly between the summers of 1929 and 1932 by the school of social sciences and administration of the University of Liverpool, under the direction of Mr. Caradog Jones, contains a mass of varied information on the social and industrial life of the Merseyside industrial area, based on official figures, the knowledge of experts, and a very extensive use of sample investigations and questionnaires.

Vol. I., after giving a history and general description of the area, deals with the income and expenditure of the working classes, the influence of poverty, and housing conditions. Extensive use is made of a household sample of 6906 families containing 28,845 persons; made by visiting 1 in every 30 of the working-class houses throughout the area. The sample showed 26 per cent. of families living more than one family per house, and 17 per cent. of all persons and 24 per cent. of children living under overcrowded conditions. Among the families investigated 16 per cent. of all persons and 23 per cent. of children were found to be living in poverty. (Both overcrowding and poverty were assessed according to definite standards.) A comparison with the results of a sample given in the "New Survey of London and Labour" shows that in London in 1929–30 the percentage of overcrowding was higher but the percentage of poverty lower—owing to the much lower unemployment percentage in London.

Vol. II. deals with the industries and occupations of Merseyside and the trend of employment and unemployment. It incorporates the material provided in 1932 by the University of Liverpool for the Board of Trade. Merseyside is at present a "depressed area" and the major part of its economic activity, that concerned with shipping and distribution, "is chiefly governed by conditions so far reaching in character that only forces set in motion on an international scale can radically improve them." There is a very interesting discussion of the probable effects of tariffs on the different industries, with a plea that similar information should be collected for other areas.

Vol. III. deals in part with local government in general and the functions of public health, public assistance, elementary and secondary education. The Merseyside industrial area is a striking example of the lack of correspondence between boundaries and the social and economic units of population. Its 1,300,000 of population, closely united socially and industrially, is divided between the four county boroughs of Liverpool, Bootle, Birkenhead, and Wallasey, six urban and two rural districts, and the administrative counties of Lancaster and Cheshire. A similar position was revealed in the survey of Tyneside made a few years ago, where the population of the area surveyed came under the control of 15 local authorities. The remainder of this volume is mainly taken up with an investigation into various subnormal types of population, a consideration of the social services and differential fertility, and a record of sample inquiries about the occupations and interests of adolescents, the uses of leisure, infant welfare, and church attendance.

The use of the method of sampling in unusual types of inquiries makes this volume of particular interest. In an inquiry on infant welfare two samples were taken: one consisted of all the births notified in Liverpool during a fortnight in February, 1930—717 in all; the other of 200 births in families too well-to-do to be supervised by the health visitors. As far as possible a record was kept of every baby over a period of two years. In Liverpool, as a whole, more females than males survived and made good progress, but this was true only of the inner districts, containing most of the poor parts of the city. Of the babies in the good types of artisan families 80 per cent. made good progress and only 5 per cent. died, as compared with 45 per cent. and 19 per cent. respectively in the poorest types of families. The child without brothers or sisters had the best record. Premature babies showed a large proportion of deaths (about 40 per cent.) and the survivors made less satisfactory progress than the average. The proportion of breast feeding was higher in the poorer families than in those better off, and in both cases the best results were with the breast-fed babies. In the small number of cases where the mother went out to work the child's progress did not seem to be seriously affected. On the other hand, of the babies in families living in overcrowded conditions, 20 per cent. died and only 38 per cent. made good progress.

The inquiry on church attendance deals mainly with the types of attenders at places of worship. Liverpool is not typical of the whole country in that about 30 per cent. of the population are Roman Catholics. On the basis of censuses made in the past by the *Liverpool Post*, the survey estimates 15–20 per cent. of the population as church attenders. A census of attendance of those aged over 14 taken in two Tyneside towns in 1928 gave a rather similar figure of about 20 per cent. in Wallsend and about 12 per cent. in South Shields. In Liverpool samples were taken of congregations in May, 1930, and 1931, questionnaires being distributed to those attending. The 9087 replies from persons over 14 showed a considerable predominance of women and girls over men and boys in all the three groups considered—Church of England, Roman Catholic, and Free Churches—the predominance being greatest in the Church of England. (The figures for the two Tyneside towns gave similar results for sex distribution.) In respect of sex, age, marital state, and occupation the Roman Catholic congregations resembled the general population more than did the congregations of the other two groups. In these latter there was a larger proportion of the young (aged 14–29) and the old as compared with the middle aged, of single as compared with married women, and of non-manual as compared with manual workers.

Anyone who even dips into this survey must be impressed with the enormous amount of work which has been devoted to its making by many individuals. The results will no doubt be of most interest to those who know the area surveyed, but the authors have been remarkably successful in their appeal to a far wider circle. In many directions the survey adds to our knowledge of the subjects covered.

Japanese Medicine

By Y. Fujikawa, M.D. Translated from the German by John Ruhrah, M.D. New York: Paul Hoeber. London: H. K. Lewis and Co., Ltd. 1934. Pp. 114. 7s. 6d.

We recently reviewed a pendant to this little book dealing with Chinese medicine, but the similarity between the two is only on the surface. The literary history of medicine in China begins 3000 years earlier than the mythical period in the case of Japan, which barely predates Christian era. As, however, there is evidence of intercourse between the Chinese and Japanese more than 1000 years before that era, it is probable that some sort of medical inter-relations had been established before Japan can be said to have had a medical science of her own. Certainly when Buddhism arrived by way of Korea the writings brought by the Buddhist priests were written in Chinese, and everyone who desired to study the new teachings had to learn Chinese. Dr. Fujikawa enumerates eight Chinese medical text-books which were necessary from the beginning to the Japanese medical student.

As we approach the definite historic era of A.D. 1100 we find that the Japanese had themselves produced a considerable number of medical works, though here again the oldest existing medical book of Japan is stated to be partly based on medical treatises introduced from China, abstracts from the Chinese classics forming the text for Japanese editorial observation. The anatomy and physiology of this period, termed by the author the Heian period, and including the 400 years between 784 B.C. and A.D. 1186, are purely fantastic, and their Chinese origin can be readily detected. The basic assumption of the physiological teaching was the existence of the double principle, positive or masculine and negative or feminine; these are the creators of the living body and circulate with the blood and pneuma or air, but no explanation as to how that circulation was maintained was attempted. In general pathology the principal cause of disease was the behaviour of the pneuma, or "live air," drawn through the skin into the body, and according as it proved too hot or too cold for inhalation it worked as an activating power. The influence of the pneuma could cause any single kind of disease to be indefinitely subdivided, a fact which accounts for detailed attention to pharmacy. Medicines were prepared as pills, powders, extracts, tinctures, decoctions, vapours and suppositories, and one pharmacopœia included 81 drugs derived from minerals, 509 from plants, and 182 from animals. In surgery, the Japanese during the earlier periods were more advanced than in medicine; the treatment of wounds, ulcers, and abscesses was often logical, and there was considerable knowledge of ophthalmology. And at the same time sensible attention was paid to hygiene, clothing, housing, ventilation, and foodstuffs.

The development of medical science in the country throughout dates corresponding to the early middle ages in Europe is set out briefly, and the references to literature show that more sources of information exist than might have been suspected. The political conditions of Japan were often stormy when the influence of China would again become paramount, for Japanese savants repaired to the more peaceful neighbouring country to study their science. But real advances came slowly, for during the long Yedo period (A.D. 1616–1876) the pathology of Japanese doctors remained wholly fanciful, resting on theories which are impossible to follow in spite of Dr. Fujikawa's careful analysis of them. The Japanese, however, had detected the romantic nature of much of their anatomy and physiology, and when increasing communications with Europe placed at the disposal of students at the end of the eighteenth century accurate descriptions of the internal organs there were many observers able to take advantage of Western learning.

The recent history of medicine in Japan is supplied by Dr. Kageyas Amano, who enumerates briefly the fine contributions to modern science which followed in the nineteenth century upon the introduction of Western learning. Takamine, Kitasato, Shiga, Noguchi, and Yamagiwa furnished in remarkable succession their additions to the world's wisdom, and the contrast of the last quarter of this little volume with the preceding three-quarters is sheerly dramatic. We have here an almost incredible picture of development.

The 1933 Year Book of Pediatrics

Edited by Isaac A. Abt, D.Sc., M.D., Professor of Pediatrics, Northwestern University Medical School. With the collaboration of Arthur F. Abt, B.S., M.D., Associate in Pediatrics, Northwestern University Medical School. Chicago: Year Book Publishers Inc.; London: H. K. Lewis and Co., Ltd. 1934. Pp. 548. 10s. 6d.

The editors of this volume in what is now a well-known series have again carried out the laborious and extremely useful task of abstracting the year's pædiatric literature. If the attention given to the publications that have appeared in American and English periodicals seems at first sight disproportionately great, it will be found that the essentials of a great number of papers in German, French, Italian, Spanish, and Dutch have been supplied as well. In this volume the section devoted to tuberculosis is one of the most complete; it is interesting to see how the English and American conception of pulmonary infection in childhood is coming into line with the continental view, and how the much-debated "epituberculosis" is gradually being accorded a local habitation, though not on quite the same ground as was originally claimed for it. Amongst recently described diseases that have received increasing recognition during the past year is von Gierke's glycogenic disease, of which no less than seven cases have been reported. The editor appropriately quotes in his introduction the foreword provided by Prof. Adelbert Czerny to the new recruit to the ranks of pædiatric journals, the *Indian Journal of Pediatrics*, the first number of which was published in Calcutta in October, 1933.

The time is long past when any practising clinician can hope to read at all thoroughly the original papers in the world literature dealing even with his own specialty, but this series of Year Books will at least enable him to take note of the more important, and this volume is a good sample of their worth.

THE LANCET

LONDON: SATURDAY, AUGUST 4, 1934

THE PATIENT'S CONFIDENCE

Two months ago we expressed sympathy with the American surgeon who had been fined and imprisoned for not disclosing to the police the fact that he had treated the injuries of JOHN DILLINGER, the gunman. Our enthusiasm for a principle proved somewhat provocative. A lay contemporary was ready to ascribe the surgeon's conduct to "blue funk" rather than to an honourable observance of the oath of Hippocrates. This comment was neutralised by another from a correspondent in the State of Minnesota. Writing of matters known in England mainly through dramatic fiction or travellers' tales, he warned us that gangsters have their underworld doctors and lawyers in every large city in America. Our heroics, in fact, were misplaced; we ought to judge the surgeon by his patients; the professional advisers of the gunman are not so much terrorised as profitably involved in a nation-wide conspiracy of large-scale murder. Among other commentators the *Listener* remarked that it is a dangerous doctrine that makes the surgery a sanctuary for the criminal and "places a man's loyalty to his profession above his loyalty to the State." This antithesis is stated in a form we cannot accept. The surgeon's obligation of secrecy is not founded on loyalty to his profession but on loyalty to the public—that is to say, loyalty to those members of the public who engage his services. The *Listener* was reminded of the conflict of loyalties devised with characteristic skill by GALSWORTHY in his play "Escape." The playwright, by committing a chivalrous gentleman to Dartmoor prison for an unfortunate accident in the first scene, was perhaps unfairly careful to secure the sympathy of the audience for the criminal from the outset. John Dillinger was probably a less lovable figure than Nicholas Hannen in the play. In fact, as the *Listener* concludes, circumstances alter cases. The conclusion is irresistible. The surgeon's duty of secrecy is based on public interest, but admittedly there may be awkward conflicts, and in other matters besides crime, when fresh aspects of public policy appear. Lord RIDDELL, who has written an illuminating essay on this subject, propounded the case of the engine-driver who thinks he is suffering from nervous exhaustion. The doctor, diagnosing G.P.I., tells the patient he is not fit to drive his train; the patient disagrees. Passengers' lives being thus in peril, is the doctor justified in reporting the facts to the railway company? The usual professional solution is to say that the doctor must prevail upon the patient to disclose the facts himself. If the patient obstinately refuses, how is the deadlock to be ended? Some analogy may be discovered in the statutory duty to notify infectious diseases; statutory examination of engine-drivers might create a similar duty of disclosure. Meanwhile the instance suffices to indicate the admitted conflict. There are, as Lord Justice BANKES observed in another connexion (in Weld-Blundell *v.* Stephens), "cases where public policy is better served by respecting the confidence than by abusing it." Nobody doubts that there are also cases where a strong argument can be advanced for disclosure.

The incident of Dillinger and his surgeon leads to a special consideration of professional confidence in relation to criminal cases. Here we shall naturally find that the medical tradition of non-disclosure is unacceptable to judges, directors of public prosecutions and police. This difference of outlook has been particularly marked in the demands made upon doctors to report cases where criminal abortion is suspected—demands which the medical profession has not always felt able to concede.[1] It is worth while to clear the ground by making certain distinctions. In the first place we can distinguish the duty to answer questions in the witness-box under direction of a judge from the disputed duty to report to the police what a patient may have said in the surgery. The doctor's duty as a witness may involve breach of his patient's confidence; the judge may insist on an answer and the witness must then decide how far he can carry his protest. Here the position remains as defined by the great Lord MANSFIELD in 1776 at the trial of the so-called Duchess of Kingston for bigamy. CÆSAR HAWKINS, the celebrated surgeon, was called as a witness and deprecated answering on matters within the rule of professional secrecy. MANSFIELD delivered the decision of the court that he must answer. "If a surgeon was voluntarily to reveal these secrets, to be sure he would be guilty of a breach of honour and of great indiscretion; but to give that information in a court of justice, which by the law of the land he is bound to do, will never be imputed to him as any indiscretion whatever." If we may first distinguish the doctor's duty as an actual witness in court from the demand that he should telephone to Scotland Yard any suspicions he may entertain about his patients, there is a second distinction to be made. It is one thing to give professional assistance in a deliberate plan to commit a crime—for instance, for a doctor to help a wife to poison her husband; that would be a criminal conspiracy. It is another thing to give medical treatment to a man who may be a criminal. The law is naturally prepared to punish those who aid and abet a felony and those who harbour the felon; but physician and surgeon are in a sense non-combatants. "It seems," wrote HALE, the famous 17th-century jurist, "even by the common law, if a physician or chirurgeon minister help to an offender sick or wounded, though he do know him to be an offender, even in treason this makes him not a traitor; for it is done upon the account of common humanity, not *intuitu criminis vel criminosi*; but it will be misprision of treason if he know it and do not discover him." The mysteries of misprision of treason we can leave aside until some registered medical practitioner is accused of the offence. In view of Hale's reminder that much may depend on the doctor's knowledge of crime or criminal, we may emphasise that suspicion is not knowledge nor is it the doctor's business to play the amateur detective. If the victim of a traffic casualty is brought to the surgery, must the patient be cross-examined as to the possibility of his having been criminally negligent? If so, it will be only fair to warn him that anything he may say in the surgeon's presence will be taken down and used in evidence against him.

---

[1] See, for example, THE LANCET, 1932, ii., 847, 862, 915.

The spectacular eminence of the Dillinger episode spoils the perspective. To see the principle of professional secrecy in proper proportion we must look at legal as well as medical practice. The confidences which pass between client and solicitor are absolutely privileged from disclosure. The ground of this rule, it has been authoritatively said, is not any special importance of the legal profession but the expedience of securing to every man the full protection of the laws; "a man would be practically precluded from obtaining the aid of skilled advisers if his communications with them were not thus protected from publicity." The rule is far-reaching. An attorney was once subpœnaed to give evidence and to produce certain papers before a grand jury upon an indictment for forgery preferred against one of his clients by whom the papers had been confidentially communicated to him. The court held that he was not compellable to produce the papers against his client, Lord Mansfield ruling that, instead of so producing the papers, the attorney ought, on receiving the subpœna, forthwith to have handed them over to the client. The privilege which English law recognises in the case of solicitor and client is no better justified than the privilege which English law declines to recognise in the case of doctor and patient. Members of the public can entrust their secrets to a solicitor with a guarantee against disclosure because, if they cannot fully confide in him, they lose the full protection of the laws. Members of the public may well demand similar non-disclosure on the part of their medical adviser lest they lose the full advantage of his advice. The judicial denial of medical privilege in England has been declared by a well-known legal text-book to be a rule "harsh in itself, of questionable policy and at variance with the practice and *code pénal* in France and the statute law in some of the United States." Advice on health is not of less public interest than advice on rights of property. For doctor or surgeon to win the patient's confidence is half the battle. The medical profession offers the public all the secrecy within its power. Unless the doctor is known to respect the patient's confidence, he will get neither the patient nor the confidence: but the principle of respect for confidence exists for the benefit of the public, not for the benefit of the doctor.

SKELETAL DISEASES OF DOMESTICATED ANIMALS

Last year, under the auspices of London University, Sir Arnold Theiler delivered at the Royal Veterinary College, London, three lectures on the osteodystrophic diseases of domesticated animals, and these have now been made accessible to a wider circle.[1] South Africa has offered him and his colleagues at the Onderstepoort department of veterinary research, Dr. P. J. Du Toit and Dr. H. H. Green, exceptional opportunity for the study of some of these diseases. Stijfsiekte, or stiff-sickness, is a phosphorus deficiency disease of cattle. The animals most affected are heifers with the first calf, cows in lactation, and growing cattle. They may develop an intense craving for bones, known as osteophagia, which compels them to travel long distances to find carcasses, and they may even kill and eat young lambs. On the veld the sound of crunching bones may sometimes be heard in the distance. The disease shows itself in retardation of growth and abnormal skeletal development, viz., thickening of the epiphyses of the leg bones, most pronounced at the metacarpus and first phalangeal joints. The gait is stiff and lame. In the young lactating animal there is usually rapid loss of condition, the lameness may become acute, and the animal tends to walk on its heels with hooves growing out. The bones may become fragile and fracture of the ribs and pelvis has been observed. Abnormal posture results, sometimes with curved spine, and in the last stages stiffness and lameness may prevent the animal from rising, and death from cachexia ensues. In the affected areas the soil and grass are found to be deficient in phosphorus—the hay may contain less than one-fifth of the normal amount—leading to a low level of inorganic phosphorus in the blood plasma, which may contain less than 2 mg. per 100 c.cm. There is no defect however in the calcium content of the fodder. Theiler and his associates have reproduced experimentally such aphosphorosis, and have shown it to be identical with the naturally occurring stijfsiekte. Low phosphorus rations were fed to heifers 12–18 months old in all of which the disease picture was produced in spite of daily exercise in brilliant sunshine, and no matter whether the calcium ration was high or low. The inorganic phosphorus of the plasma sometimes dropped to 1·3 per 100 even before the disease could be diagnosed clinically; blood calcium was normal. Vitamin deficiency had no adverse effect. Of the affected animals dying or killed some showed brittle, fragile, or fractured ribs, the whole of the skeleton being too light. In sections of bone Theiler found osteomalacia and rickets, in some cases in high degree, the osteoid seams being extremely wide. Further evidence that the condition was one of pure phosphorus deficiency was found in the fact that the disease could be prevented by supplementing the grazing with bran, which contains much phosphorus and little calcium. The routine preventive is bone-meal, of which the effective weekly ration is half a pound to two pounds a head, according to growth and lactation. This simple measure not only abolishes osteophagia and stijfsiekte, but leads to an increase of milk yield, better calves, more rapid growth of young stock, and superior fattening of adult cattle.

---

[1] Veterinary Journal, April and May, 1934.

THEILER then extended his investigations to skeletal diseases of equines, using material supplied by STURGESS and CRAWFORD from Ceylon as well as collected by himself from South Africa. He was able to confirm the view that the disease known as "equine osteomalacia" by some and "osteoporosis" by others, is not strictly osteomalacia at all, but a different pathological entity more comparable to osteitis fibrosa of man. It is properly described as osteodystrophia fibrosa. Somewhat loosely applied in veterinary literature in the past, THEILER uses these terms in their precise histo-pathological sense. Thus osteomalacia is identical histologically with rickets, being the adult variety of this disease, and is diagnosed histologically principally on the evidence of broad osteoid seams. In osteodystrophia fibrosa the seams are not widened, but the bone is extensively destroyed by osteoclastic lacunar resorption; proliferation of osteogenetic fibrous tissue is unable to keep pace with the destruction. The picture is one of fibrous bone. Within the last seven years osteodystrophia fibrosa of equines has formed the subject of experimental research in Ceylon, Japan, and the Philippine Islands. Many have supposed the disease to be of dietary origin, tradition being in their favour in the sense that "miller's disease" or "bran disease" of horses must be considered as an osteodystrophia connected with one-sided feeding on cereals or bran. Bran being poor in calcium but rich in phosphorus it was suspected that osteodystrophia fibrosa was due to an unduly wide ratio of CaO/P_2O_5. Proof of this is now to hand. A survey of the experimental data makes it clear that the main cause of the disease is a diet of low calcium, high phosphorus content; the disease may, however, occur even when the calcium appears adequate if the phosphorus is grossly preponderant.

The osteodystrophic diseases of domesticated animals—rickets, osteomalacia, and osteodystrophia fibrosa—may all be regarded as dietary diseases, even if dietary factors are not alone responsible for them. Deficiency of phosphorus leads to rickets and osteomalacia in cattle, excess of phosphorus and inadequate calcium to osteodystrophia fibrosa in equines. The animals however differ in their reactions. A ration which produces osteodystrophia in the horse does not produce it in cattle—indeed that disease is apparently unknown in the bovine. In the dog rickets and osteomalacia arise from deficiency of vitamin D. The mineral metabolism of an animal normally depends upon the harmonious interaction of the three factors: vitamin D, calcium, and phosphorus. But we cannot as yet predict the effect of deficiency of one of them on any particular species of animal. Different pathological pictures appear to result from identical causes, and the same picture may be presented by diseases of which the causation is different. The part played by the endocrines and the possible significance of different mechanisms in the control of mineral metabolism is a field quite unexplored in domesticated animals. In concluding his third lecture THEILER asks himself: Why does the bovine tolerate a CaO/P_2O_5 ratio which induces osteodystrophia fibrosa in the horse; and why does the equine escape osteomalacia on pastures which induce that disease in cattle? He is unable to explain. We may yet, he thinks, have to call in a concomitant disturbance of the parathyroids, the result of toxic or infectious agencies, to provide a full explanation for the ætiology of osteodystrophia fibrosa, even though at present all the evidence may be in favour of mineral imbalance as the cause. We may hope that THEILER's work will be as successful in tracking down the different reactions of different animals to mineral deficiencies as he was in finding the causal agent, which now bears his name, of the deadly red water fever of cattle.

PROGRESS OF THE BED-BUG

As we noted last week in these columns the flea is declining. But on another page of the same issue (p. 222) the progress of the bed-bug was celebrated by its introduction as a "fundamental housing problem" into the House of Lords. As Lord CRAWFORD rightly complained, the bed-bug has suffered in the past from a taboo which has served to conceal a serious question of public health, and subsequent discussion showed that even in so well-informed a body as the House of Lords, knowledge of it is distinctly patchy. In other spheres the effects of this taboo can be surprising. It has been seriously asserted by some that to state the degree to which certain houses or districts are infested with bed-bugs is to insult our working classes; and the efforts of public health authorities to reduce this infestation have been condemned by others as unwarranted interference with the rights of (human) individuals. In the debate referred to, Lord CRAWFORD created the impression, unintentionally no doubt, that the bed-bug is a problem chiefly in new houses. That, of course, is not the case. In old-standing slum areas in London, obvious infestation has been shown to exist in 90 per cent. of the houses, the actual infestation being probably nearer to 100 per cent. But since the landlords of many of the new houses are themselves those same public authorities who are concerned in combating the bed-bug, it has come to them as something of a shock to discover that many types of council houses, with ceilings and partitions of asbestos sheeting concealing open spaces behind, provide in fact ideal haunts for the bed-bug—haunts which it is not slow to colonise, and from which existing measures of fumigation and so forth seem powerless to expel it. It is this accident of modern construction which has brought the bed-bug to the fore. Perhaps some simple modifications in construction may defeat the bed-bug in the future. Housing schemes cannot be indefinitely suspended until such methods have been evolved, but anyone familiar with the magnitude and complexity of the problem will endorse Lord CRAWFORD's plea that a few pounds devoted to research along insecticidal and biological lines, as advocated by the Ministry of Health's own committee,[1] would be well employed. At the moment the difficulties appear so great that the prospect is depressing. But when one recalls that, little more than a hundred years ago, probably all houses in this country harboured a greater or lesser number of bed-bugs, whereas at the present day, even in London itself, at least a quarter of the houses seem to be free of them, there is ground for hope that the inculcation of cleanly ideas and practices, coupled with more strenuous activities on the part of the sanitary authorities, may in time reduce the incidence of this infestation still further. That the community, from the House of Lords and the Ministry of Health downwards, should have become what Americans would call "bed-bug conscious" is an important step.

ANNOTATIONS

THE CASE OF THE DEAF

DEAF people, as has been frequently pointed out, receive little of the profuse sympathy expended on the blind: but is their deprivation lighter? The blind person gives less trouble to those about him than the deaf, though this may not be immediately obvious. He must be led, it is true, but all love to lead him, whereas a deaf person cannot be helped thus easily. If he has some hearing capacity others feel ridiculous when going to his aid by shouting at him—they do not shout because they are angry, as those around may assume, but, alas, they sometimes get angry because they are shouting. And the totally deaf subject throws another sort of responsibility upon his companions; they must speak always facing him, so that he can watch their lips, and their attention may be strained to follow his speech. Few have sufficient courtesy and patience to make the deaf feel that their disability is of small account, and consequently many deaf persons live cut off from much normal intercourse. The situation has been forcibly and beautifully put by Miss Margaret Monro in a small book addressed to the deaf and their friends, illustrating how much the deaf can help themselves, but how much self-help depends on the intelligent sympathy of their environment. To a great extent most of what follows forms a comment on Miss Monro's words, which should be read by all who appreciate what general society loses through the existing apathy towards the deaf among us.[1]

No special legislation exists to protect the interests of the deaf apart from that which entitles deaf children to suitable education. So far their cause has been chiefly the concern of the National Institute for the Deaf, a voluntary body, and of the Counties Associations for the deaf, affiliated to it, and including in their membership both voluntary societies and those local authorities sufficiently interested to join. The National Institute for the Deaf is maintaining three organisations for deaf women and working deaf boys, and acts as a clearing house for the work of the County Associations; it is largely administrative. How the deaf are helped, and how they may help themselves, is well set out in "All About the Deaf," a handbook of information published by the Institute.[2] This is a revised edition of a previous publication issued in 1929, and Lord Charnwood, the president of the Institute, lays emphasis in his preface on the distinction between the cases of the deafened and the born deaf with whom the prevention of deafness has not to be considered, while this is one of the chief objects for which the Institute exists. The handbook contains lists of ear hospitals, homes maintained by the Institute, and other homes and hostels for the born deaf, schools and welfare societies, schools for the partially deaf—a scanty list—training schools for teachers, scholarships for the deaf, and societies granting pensions. It also includes authoritative articles upon the ascertainment and prevention of deafness, the use of the gramophone and audiometer and upon the development of speech in the child born deaf. A section is devoted to existing legal provisions which at present are solely devoted to the educational needs of deaf children. No State inquiry into the conditions of the deaf had been made since 1886 until the Ministry of Health and the Board of Education, in 1930, appointed Dr. Eichholz "to obtain fuller information than is at present available on the position in industry of deaf and dumb persons and of the facilities for their education and training and securing employment." This report was published in 1932, and the recommendations from it are printed in the handbook and criticised in two memoranda, drawn up by the Institute and by the National College of Teachers of the Deaf respectively. Both deprecate the lukewarm tone of the report, for though they value it as embodying the result of the first investigation by the State into the needs of the deaf over school age, they feel that far too little attention has been given, in it, to the needs of the deafened, who form a much larger class than the born deaf. Members of the Institute are anxious to see the compulsory school age lowered to five years for children born deaf, for if speech is to be acquired it must be acquired young; at present these children need not attend school until the age of seven. For deafened children they would like to see an extension of suitable educational provisions and opportunities for school leavers to acquire vocational training. Earlier old age pensions for those who through deafness are unable to support themselves by their own labour would bring the deaf into line with the blind, and a request for this reform seems just.

These, and other proposals, were discussed at length at a conference of the Institute and the Counties Associations held last December, under the chairmanship of Lord Charnwood, the proceedings at which have just appeared.[3] The practical outcome of Dr. Eichholz's report, so far, has been the issue of two circulars by the Ministry of Health: one of these urges local authorities to make use of the powers they possess to contribute to associations in aid of the deaf and dumb, so helping them to place their beneficiaries in employment; the second circular, addressed to maternity and child welfare authorities, draws their attention to the importance of the early treatment of ear disease following the exanthemata due to nose and throat defects. The feeling of the conference as revealed by the published procedure was that these circulars urging, as they do, only a more extended use of existing provisions, do not go nearly far enough. Mr. Maurice Birley, chairman of the Institute, thought that existing provisions, in so far as they were compulsory, began too late and ended too early, being only concerned with nine years of a deaf person's life. The conference was strongly in favour of asking for a "Deaf Persons Act" which should guard the interests of the deaf in much the same way that the interests of the blind are guarded. Dr. James Kerr, representing the Scottish National Association for the Deaf, remarked that a large number of deaf people begin to go down after middle age and end as dependants: eight times as many deaf people as normal people are admitted to workhouses; it would be cheaper to help them to help themselves than to support them outright in this way. A Deaf Persons Act need not involve nearly as much national expenditure as the Blind Persons Act, because the blind must usually spend their whole working life in workshops, whereas the deaf, when trained, can find a place in the regular labour market. The three publications, here reviewed, set out the arguments for such an Act clearly and without padding or gush; they deserve the attention of all.

THE BLOOD IN PREGNANCY

FROM elaborate examination of the blood in normal pregnancy Dieckmann and Wegner[1] conclude that there is an increase in both blood and plasma volume beginning in the first trimester. At term the average increase in volume is 23 per cent. and in plasma 25 per cent., and at eight weeks postpartum there is an average decrease of 16 per cent. in both. These workers describe, as others have done, a definite decrease in the percentage of hæmoglobin, the number of red cells for 100 c.cm. of blood, and the volume of packed red cells. This decrease is, they claim, only relative; if the absolute figures are considered instead of percentages there is an increase both in hæmoglobin and red cells. The increase in plasma volume, however, is greater, so that the hæmoglobin and red cells show a relative decrease and absolute increase. Dieckmann and Wegner think this increase in blood and plasma volume and decrease in serum proteins, red cells, and hæmoglobin to be an effort on the part of the body to reduce the viscosity of the blood and thus to reduce the amount of work done by the heart, while at the same time the increased maternal tissue and the fœtus are adequately supplied. In fact they seem to support the old theory of an apparent physiological anæmia of pregnancy. The patients they investigated were, however, from the hospital class, and in view of the high incidence of chronic iron deficiency anæmia in women of this class and of the demands made for iron during pregnancy it appears possible that the degree of apparent anæmia that they record as physiological is really due to an insufficient intake of iron. Only further research can settle this point. They suggest that a hæmoglobin under 10 g. per 100 c.cm. of blood should be regarded as pathological, and since they accept Wintrobe's figure of 14·3 g. per 100 c.cm. as normal their pathological level is a low one. They also describe a fall in serum proteins per kilogramme of body-weight, and an increase in the total amount of serum protein, accompanied by an increase in plasma fibrin. The variations in plasma cholesterol in the same women is, they state, "enormous." There is an increase in cholesterol both per kilogramme of body-weight and when calculated in absolute figures, and this increase they consider to be associated "with other changes in the chemical equilibrium, which is so markedly disturbed in pregnancy."

RESEARCH ON CANCER

THE Cancer Control Organisation for Edinburgh and South-East Scotland was founded with the object of encouraging and coördinating clinical, pathological, and statistical research on cancer, of facilitating the earlier diagnosis and treatment of the cancer patient, and of establishing an efficient follow-up system for each case. The booklet[1] of 72 pages before us is the first report of the organisation, and it is intended to submit a similar report every year. The organisation has the support of many of the leading clinicians and pathologists of Edinburgh and the surrounding district. Mr. J. J. M. Shaw, chairman of the executive committee, gives in a few pages a clear exposition of the present state of the cancer problem as it affects man and explains the scheme of the organisation, which aims at obtaining a record of the treatment and results of every cancer patient in the area. The collaboration of the general practitioner is assisted by the provision of vouchers, which enable him to send necessitous patients without expense to Edinburgh for purposes of diagnosis, treatment, or for subsequent appearances at the follow-up department. The booklet contains the results obtained since 1930. The clinical material is divided according to sites in clear tabular form, with short explanatory remarks. With the lapse of time the reports will greatly increase in value by giving clear evidence of the efficacy of the different forms of treatment adopted for each site. The work of the organisation is to be welcomed. Its annual cost is estimated by the Marquis of Linlithgow, one of the hon. presidents, at £5000. Since the results will benefit the general public the organisation deserves a liberal financial support.

THE DEFINITION OF BLINDNESS

THE number of people on the blind register on March 31st, 1933, was 63,408. This figure necessarily depends on the definition and arrangements for certification. In its annual report[2] the Advisory Committee on the Blind recalls that the Minister of Health has repeatedly emphasised the desirability of having the examination made by medical practitioners specially skilled in ophthalmology. In a circular issued last October he entered more fully into particulars.

> A medical practitioner with special experience in ophthalmology should be taken to mean one "who devotes his or her whole time to the practice of ophthalmology in all its branches or who is in charge of the ophthalmological department of a general hospital of not less than 100 beds; failing such practitioner, one who *holds* a diploma in ophthalmology from a university (or other examining body recognised by the General Medical Council)."

This recommendation has now been adopted by 30 county councils and 47 county borough councils, and others are following suit. The chief difficulty, of course, is with the borderline cases. According to the official definition, a patient with vision between 3/60 and 6/60 *with full visual field is not to be certified* as blind, even though he has nystagmus. He is not, it may be said, debarred from some occupation for which eyesight is essential, such as some sorts of work on a farm, but in the present economic condition of the country the chances are that he will drift into the army of permanently unemployed. These cases form a difficult problem for the certifying surgeon, and it is quite possible that where one surgeon would refuse another would consent to certify. Would it not be a good plan for these surgeons to get together and compare notes about their actual practice, and for the Minister of Health to confer with them once more?

THE EXPANSION OF THE R.A.F.

THE Air Ministry has announced a new system of entry designed to increase the number of pilots in the Air Force Reserve. The system provides for free flying tuition, and vacancies will occur for 40 candidates for direct appointment to commissions. Those only for the present will be eligible who have served in one of the squadrons maintained at Oxford and Cambridge and have obtained some flying experience and the certificate of efficiency. The selected candidates will commence their training at various dates in September at one of the reserve flying schools and the initial course will consist of a fortnight's instruction and 50 hours' flying, which would normally occupy about seven weeks. In addition to these 40 appointments applications are invited from civil pilots up to the age of 28 who are experienced up to the point needed to [illegible]st. There is no mention of the [illegible] passed any physical examination or of successful submission to any psychological tests. Perhaps both the civil pilots and the University candidates will be considered by previous training to have already satisfied official scrutiny in these respects, but the fact is not mentioned in the communiqué from the Air Ministry, while assuredly the public will expect reassurance on the point.

RADIOGRAPHY OF THE SELLA TURCICA

THE form of the sella turcica is affected not only by tumours of the pituitary body but also by tumours in its immediate neighbourhood and in remoter parts of the intracranial cavity. These changes have been analysed in considerable detail by Dr. Felix Smith[1] in a radiographic study of 500 cases of intracranial tumour at Prof. Brouwer's neurological clinic in Amsterdam. Abnormalities in the sella were found in 72 of them. A precise correlation between the type of sellar enlargement and the disposition of the tumour which is responsible for it appears, however, to be impossible; there is too much variability in such factors as the rate of growth of the tumour and the possibility, in young subjects, of compensation by widening of the sutures.

The pituitary adenomata cause in general a destruction of the floor, dorsum, and posterior clinoid processes of the sella without other radiological evidence of increased intracranial pressure. In this connexion it is noteworthy that P. Puech and L. Stuhl,[2] working at Vincent's clinic, report that they are able to distinguish radiologically between chromophobe and acidophil adenomata. In the former, they say, the sella turcica is enlarged in all dimensions but especially in the antero-posterior, while the bony walls of the sella are greatly atrophied. In the acidophil adenomata, on the other hand, the increase *in the size of the sella is principally in the vertical* direction and the walls, even while showing evidence of erosion, are thick. They attach great importance to the observation of an increased prominence of the tuberculum sellæ *in the acidophil type and* consider that this "bec acromégalique" (as they term it) is a diagnostic feature. At the same time it must be remembered that intracranial tumours, other than pituitary adenomata, may produce a very considerable destruction of the sella. Thus Smith has found that 58 per cent. of cases of supratentorial meningiomata and 52 per cent. of supratentorial gliomata gave rise to enlargement of the sella. In the gliomata this change was observed rather more often in the radiograms than were digital impressions and widening of the sutures—that is to say, evidence of a general increase of pressure. The combination of these general pressure signs and enlargement of the pituitary fossa is commoner in adults than in children, because in the latter compensation takes place through thinning of the cranium and separation of its sutures. Smith concludes that "a radiograph showing an enlarged sella in the presence of well-marked signs of increased intracranial pressure is almost certainly not that of a case of pituitary adenoma, and this even when the fossa is enlarged to the point of *obliteration of the sphenoid air sinus and complete* destruction of the posterior clinoid processes and the dorsum sellæ."

INDUSTRIAL HEALTH

THERE is so much medical research into diseases, their causes, treatment and prevention, that we are liable to forget the need for knowledge relating to health. The latest report[1] of the Industrial Health Research Board reminds us that study of health *reveals more problems than it solves.* Data are lacking about the physical condition of the working population as a whole, and about the incidence and kind of ill-health experienced in various occupations. *Initial difficulties* include the establishment of norms of physical fitness and of rates of sickness; indeed, the Board has to devise its own methods of approach and its own technique for each problem. Output, at best an indirect measure of activity, is no longer a sufficient criterion of health; yet it remains the only one available, except when some specific occupational disorder is under examination. An extension in the near future of firms employing their own medical staff and keeping records in comparable forms, seems to be the only hope for answering such a question as "Do puddlers suffer in excess from rheumatism?" Meanwhile, useful inquiry continues into environmental conditions. Improved lighting as tile-pressing gave an increased output ranging from 6 to 14 per cent.; noise has been shown to hamper the performance of weavers; warmth, ventilation and radiant heat affect the comfort of workers and can be scientifically adjusted. *Physical data are being* collected concerning men in different industrial occupations, and renewed attention is being directed to the psychological conditions of employment, such as personal reactions, likes and dislikes. Not least important of the investigations in progress is into accident proneness, which has already proved of such value and interest. The Board has done good work in the past, and the principles enunciated are steadily, *though slowly, being adopted in practice;* but much remains to be done in order to establish normal ranges of human physical fitness for different kinds of work, and the psychological cause of discontent and ill-health. While efforts on these lines are being made in this country, the progress of industrial medicine in civilised nations is watched by the International Labour Office at Geneva. Its report[1] for 1933 shows that world-wide action is being taken to prevent industrial poisoning from lead, mercury, phosphorus and other toxic substances, and that much is being done to meet the spread of anthrax and the ravages of silicosis, ankylostomiasis and occupational cancer. Legislation to protect women and children employed in industry is now in force in most countries, including Japan, India and China. It is fairly clear that unemployment and depression have led to malnutrition and morbidity in direct proportion to the non-existence in any country of social legislation on the lines of unemployment insurance, and throughout the report recognition is given to the part played by Great Britain in initiating and furthering industrial hygiene.

SERUM TREATMENT OF ACUTE STAPHYLOCOCCAL INFECTIONS

Dr. C. E. Dolman's work on the treatment of acute staphylococcal infections has been attracting a good deal of notice in Canada, and it is interesting to see the first two instalments of his report on it.[3] The results obtained in his 104 cases are summarised in the first paper, while the second provides a more detailed description of 40 in which blood culture was negative. The striking difference between the mortality in these "negative culture" cases (4 deaths among 40), and in the "positive" (35 among 64), shows that staphylococcal antitoxin cannot be expected to work miracles in face of an established septicæmia with multiple metastatic abscesses. The same is of course true of every other anti-serum—they are all of greatest service when employed before the disease has progressed too far—but it applies with special force to staphylococcal infections, because in these every secondary lesion means tissue destruction and the formation of a new abscess. In Dolman's series, as in others, it is exceedingly difficult to form a definite estimate of the effect of the antitoxin, because no two cases of severe staphylococcal infection can be reasonably compared. Since no satisfactory controls can be provided, one has to rely mainly on clinical evidence of improvement. Such evidence is by no means always reliable, but in the present cases it seems to indicate that antitoxin is of real value; and the significant fact appears that clinical improvement was commonly accompanied by an increase in the antitoxin content of the patient's serum. Amongst the more severe cases are 32 of acute osteomyelitis in children, in which blood culture was positive before operation, and Dolman makes the extraordinary statement that the usual mortality in such cases is approximately 50 per cent.; whereas in this country it is held by many that in osteomyelitis a positive blood culture before operation is so common as to have little prognostic significance. The serum was usually given intramuscularly, since it was found that intravenous injection gave rise to serious reactions, and the dosage was very variable. Superficial infections, such as carbuncle, seemed to respond as a rule to less than 100 c.cm.; in other cases, with a more general type of infection, the amount given was sometimes very large, reaching a total of 600 c.cm., but there were some examples in which pyæmia and toxæmia appeared to respond excellently to moderate quantities. Dolman rightly insists that the serum should be given at the earliest justifiable moment, and this presumably would tend to obviate the necessity for very large doses. In his first paper he describes the preparation of the serum, and in setting forth the various properties of staphylococcal toxin makes out a strong theoretical case for using the remedy; but in this section the criticism can be made that although he recognises the importance of staphylococcal leucocidin in the pathology of the infection, he does not seem to have tested his antiserum for its ability to neutralise this factor—the production of which by different strains does not run parallel with the production of hæmolysin. Although, however, the papers may be in some respects open to criticism, they deserve serious attention, especially perhaps from clinicians, who are apt to regard all "antisera," with one or two exceptions, as of little value, if not actually dangerous. Although the use of staphylococcal antitoxin can never take the place of skilful surgical intervention, it may often be of great assistance in combating infection and limiting its spread.

THE AMBULANCE WORK OF THE ORDER OF ST. JOHN

THERE is confusion, it seems, in the minds of many as to the constitution of the Order, and particularly as to the distinction between the St. John Ambulance Association and the St. John Ambulance Brigade. This is a pity. The primary object of the Association is the instruction of persons in first aid and kindred subjects; and that it has achieved its purpose is shown by the fact that since its inception it has issued over 2½ million certificates to students successful at its examinations, and this figure increases annually by some 40,000 or 50,000. Thus there will be found in the ranks of the police, on the railways and other forms of passenger transport, in mines, in industry, in fishing vessels, in lighthouses and among coastguards persons trained to give first aid properly. So valuable has this expert knowledge proved that qualification in its principles is often insisted upon by employers of labour and the subject has been introduced into the curriculum of schools and education establishments.

The dividing line between the Association and the Brigade is that the former issues the text-books of the Order, arranges for lectures and examinations, grants certificates to those who pass, and teaches the practice and principles of first aid to the different classes of the community just enumerated. But the certificated persons all use their first aid knowledge on the premises where they are employed, in other words the lost time is the employer's time. The Brigade give their services away from the place of employment, in their own time and at their own expense. This is a body of voluntary unpaid workers of whom there are in this country some 60,000 men and women, and overseas some 15,000. They practise in their spare time so that they may retain and improve their knowledge of first aid, and they give up their leisure in the evenings and at week-ends and holidays to the service of the public.

The call on the services of the Brigade to-day has been made acute by the development of motoring, bringing a sad roll of accidents in its train. The motor abuses are being treated homœopathically by the motor ambulance service of the Brigade. This can now set over 250 ambulances in action and so relieve the local police in the case of street and road accidents, in addition to transporting ordinary medical cases to centres of treatment.

CALMETTE'S ORDEAL

To the July number of the "Annals of Medical History" (New Series, Vol. 6, No. 4) Dr. K. E. Birkhaug, of Paris, communicates a short biography of Calmette to which we must apply the familiar adjective of charming. Both the facts of Calmette's wisdom and the traits of Calmette's character are brought out clearly, and certain passages in which the hardships inflicted on the French population by the German invaders in the early part of the war are illustrated by the methods employed to involve Calmette in charges of espionage which, if established, would have cost his life. When he was taken prisoner in his laboratory at the capture of Lille, he was accused of sending wireless messages to the French headquarters, it being suggested that his experimental pigeons were employed as messengers. His laboratory was ransacked and (damning fact) certain of his pigeons were found to be ringed with serial numbers. These pigeons, Calmette declared, were being employed in an investigation into the transmission of fowl tuberculosis, but the explanation was received with incredulity and the pathologist was placed under a threatening guard. Never was the value of keeping orderly records more dramatically shown. Calmette's files were searched through, and the bill of purchase of the birds was found, proving that the birds when *delivered were already distinguished by serial numbers.* The numbers could not therefore have reference to any secret code. An autopsy of the birds was ordered and was performed by a German pathologist, but only one pigeon was examined. It proved to be tuberculous and the accusation against Calmette was withdrawn but without apology. Calmette's comment is curious. "Fate," he said, "has played me a great boon, for among all the pigeons inoculated with the tuberculous material the pigeon examined was the only one that had contracted tuberculosis."

FINANCIAL SITUATION OF THE LONDON VOLUNTARY HOSPITALS

In its annual statistical review of last year,[1] King Edward's Fund *is able to record two remarkable facts.* In the first place the total maintenance income of the London voluntary hospitals exceeded £4,000,000 —which is unprecedented. Secondly, and perhaps more important, the number of hospitals with surpluses was higher than ever before, while the number and aggregate total of deficits were lower than ever. The voluntary gifts to the maintenance of the 145 hospitals covered in the review amounted to £1,830,000, or £133,000 more than in 1932. This was due to an increase of £152,000 in legacies, and these of course fluctuate in amount, though they have never in the last five years been less than £357,000. When receipts for building and endowment are included, the sum of the voluntary gifts in 1933 was no less than £2,239,000, an increase of £65,000 over 1932, while "receipts for services" again showed an advance, reaching a total of £1,536,000. The increase of £167,000 in the total income of the year more than covered the small increase of £29,000 in maintenance expenditure, and the net result was that the aggregate surplus of income over expenditure was £242,000, the highest recorded for ten years. Again, the number of hospitals with surpluses increased from 85 to 98, and those with deficits decreased from 60 to 47; the total amount of the surpluses rose from £201,000 to £303,000, and the total amount of the deficits fell from £97,000 to £61,000. The authorities of the Fund have good reason to congratulate themselves on these figures, which testify, it is held, how well in the aggregate, throughout the recent years of financial pressure, the current needs of the hospitals have been met, and how much has been done to *improve and extend their accommodation* and equipment.

RADIOTHERAPY OF UTERINE CANCER

In connexion with the international congress of radiology just concluded at Zurich, the Health Organisation of the League of Nations convened a conference to advise on the further prosecution of its international inquiry into the results of the treatment of utrine cancer by radium and X rays. At *this* conference, which met from July 21st to 23rd, Sir George Buchanan and Dr. Boudreau represented the Health Committee of the League, and the experts attending included Sir Comyns Berkeley and Colonel A. B. Smallman (England), Prof. Lacassagne (France), Prof. G. Forssel and Dr. Heyman (Sweden), Prof. van Rooy and Dr. Jansen (Holland), and Prof. Murdoch (Belgium). The Conference recommended that statistical statements with commentary should be annually issued, beginning next year, and relating especially to survivals for a minimum period of five years after the initial treatment. The principal object of these statements is regularly to present statistical information about the results of radiotherapy applied to patients suffering from cancer of the cervix at different stages when certain agreed rules for compilation of the data have been observed. It is proposed that the data should be obtained through special correspondents in different countries, and that the annual statements should be prepared under the advice of a small advisory council appointed by the Health Committee of the League.

FACTORIES AND WORKSHOPS

The annual report of the Chief Inspector of Factories and Workshops for 1933 is published this week (H.M. Stationery Office. 2*s.* 6*d.*). *It includes* a general description of industrial development, numerical summaries of the accidents falling under the indicated headings, notes on the safety organisations, and on the accident rates in the different industries. *Sections on health and employment* precede one describing certain large welfare schemes, and the report closes with a series of tabular statements supporting the general conclusions of the document.

INDEX TO "THE LANCET," VOL. I., 1934.

The Index and Title-page to Vol. I., 1934, which was completed with the issue of June 30th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of The Lancet, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Large Bequest to a Cottage Hospital.—It *is* now announced that the sum payable to Melksham Cottage Hospital, Wiltshire, under the will of the late Mrs. L. Ludlow-Bruges will be nearly £196,000. The hospital has at present 30 beds and its invested funds are about £2000.

PROGNOSIS

A Series of Signed Articles contributed by invitation

XIII.—PROGNOSIS IN INJURIES OF THE ELBOW-JOINT

INJURIES about the elbow-joint give rise to more anxiety than those involving any other joint in the body. Permanent stiffness will result in a certain proportion of the cases in spite of the utmost skill and care. No joint is quicker in taking advantage of the slightest error of judgment on the part of the surgeon. Complications, some of them rarely seen elsewhere, are not very uncommon, and these may be extremely serious. On the average dislocations involve a greater risk of permanent limitation of movement than fractures, though the most serious of all complications, ischæmic paralysis, usually follows a fracture. Some of the minor fractures—e.g., of the radial head, and of the coronoid process, and separation of the internal condyle, are produced by what we might term attempted dislocation, the whole joint being severely wrenched. This explains in some cases the unexpectedly poor results, though the excessive amount of swelling should have warned the surgeon of the true nature of the damage.

In children the supra-condylar fracture of the humerus is the commonest lesion. Transcondylar fractures and separation of the epiphysis are much less common and demand no separate consideration. The fracture is very rarely compound, and if it is—the skin wound is usually no more than a puncture—the prognosis is but little affected. It is of paramount importance that in all these fractures the displacement, often considerable, should be corrected without delay. If the reduction is at least fair, if not perfect, and as a result flexion is obtained without undue force, and is maintained for a sufficient time, the prognosis in the vast majority of cases is excellent. It is essential, however, that after fixation for four weeks, movement should be restored only by relaxation of the fixation apparatus and by encouraging active use of the arm: all passive efforts to extend the joint must be avoided. Too vigorous treatment by an ambitious masseur alone can be responsible for a disastrous result unless the error be discovered in time. The worst mistake that can be made is to give an anæsthetic and forcibly to extend the joint. Such treatment invariably makes matters worse and produces the opposite effect to that anticipated. Supposing the lower fragment is still displaced behind the upper and yet, in spite of the risk, flexion well above a right angle has been achieved, the final result, although in jeopardy, is by no means hopeless. Some of these cases in which the "setting" of the fracture has failed, nevertheless give good results.

Operative reduction in a difficult case should only be considered within the first few days. Late attempts—i.e., after the first week at the most, to correct displacement by open operation are to be condemned; the prognosis will be worse rather than better after such interference. In a case seen some weeks after the injury with flexion checked by the displaced upper fragment, the outlook as regards full flexion, though bad, is not hopeless. In some cases, at any rate, as a result of absorption of the bone in front, full flexion may be gradually restored in the course of several months. Although this happy progress cannot be relied upon with confidence, the possibility should always be waited for. A not uncommon error in the setting is a tilt inwards of the lower fragment, which eventually produces the gun-stock deformity, or cubitus varus. This can be revealed by X rays after setting, and should always be looked for; an effort should be made to overcome it by a second manipulation, though this is difficult. If it is not detected till later, it is better not to operate, but to wait till extension is restored and then see whether the degree of deformity warrants osteotomy. This deformity sometimes causes considerable inconvenience, besides being unsightly.

Fracture of the elbow-joint may involve injury to one of the main nerve trunks. As a rule complete recovery follows conservative treatment. Very rarely the median nerve is gravely damaged or even divided.

TWO GRAVE COMPLICATIONS

Besides limitation of movement due to fibrosis of the capsule or permanent displacement of the fragments, two grave complications may be met with: (1) ischæmic paralysis or contracture, and (2) myositis ossificans.

Ischæmic paralysis.—This is usually associated with an excessive amount of swelling, and almost without exception a considerable degree of unreduced displacement. Possible contributing factors are flexion of the joint beyond the limits of safety under the circumstances, and tight bandaging. The complication can be avoided by adequate reduction of the displacement, by not flexing the joint till this is achieved, and by fixing the forearm at an angle somewhat lower than it is possible to flex it without undue force. Though the ischæmia is now said to be due to acute venous obstruction, feeling the radial pulse at the wrist when the joint is setting is a useful guide. If, in spite of every care, signs of ischæmia develop, considerable improvement may be achieved by freely incising the deep fascia and thus relieving tension: the degree of flexion should be reduced and the arm placed on a pillow. By these means a case with a very black outlook may eventually give an excellent result, at any rate so far as *ischæmic* contracture is concerned. If the condition is well established the prognosis is undoubtedly very bad. Though gangrene, except for a patch of skin, is uncommon, complete recovery from any but the mildest degree of this complication is impossible.

In so-called *myositis ossificans*, calcification and ossification occur in the capsule or muscles or both. Here again the early recognition and prompt treatment of the condition have a profound influence on the result. This is true of children to a far greater extent than of adults, in whom the prognosis is much less favourable. If the complication is recognised early in a child and promptly treated by complete and absolute fixation of the elbow, the opacities seen in the X ray often disappear within a few weeks, and the result may be still be perfect. If, however, abnormal shadows are seen both in front and behind, if the true nature of the trouble has not been recognised early, and particularly if it has been aggravated by injudicious attempts to force a return to mobility, then the outlook as regards mobility is extremely bad. However, even in such cases patience may eventually be rewarded. In adults the response to prompt treatment is usually disappointing, and the prognosis is much less promising, though even here movement may return after many months of fixation. Removal of the new-formed bone in the early months is worse than useless. Later, operation offers a chance of increasing the range of movement, but anything approaching a perfect result must not be expected. This complication is also met with after dislocations.

DISPLACEMENT OF THE CONDYLES

Separation of the [illegible] is probably produced by forcible [illegible] forearm, and therefore the joint may have been severely wrenched; if treated by simple flexion, as a rule the prognosis is good. The desire to avoid even the slightest disability in a lad who has shown an exceptional aptitude for games may justify operation. Occasionally the separated epicondyle is sucked into the joint and caught between the humerus and ulna, and this may occur with or without complete dislocation. Open operation is usually necessary and the prognosis is not quite so good as in simple cases. The ulnar nerve may be bruised, but usually recovers after the operation. Condylar fractures which involve the articular surface, are more serious. The external condyle is more commonly displaced in children, and, as a rule, the loose fragment is rotated on an antero-posterior axis, often through an angle of more than 90 degrees. This calls for open operation: the result, though good, is often imperfect. When the true nature of the lesion, particularly as regards the rotation of the condyle, has been overlooked, the result may be surprisingly good in spite of the fact that union has failed to occur. The carrying angle will be accentuated. By the time middle age is reached osteo-arthritic changes will be giving trouble, while in addition there is always present the possibility of neuritis of the ulnar nerve. This complication may commence many years after the fracture. Fragments chipped off the head of the radius and displaced should be removed without delay; the outlook is then good. If their removal is delayed, when superior judgment should have led to their removal earlier, the result is much less favourable.

FRACTURE OF THE NECK OF THE RADIUS

The final result in fracture of the neck of the radius depends on the ability of the surgeon by open operation to restore the head to something very close to its normal position. The younger the patient the more likely is this to be achieved. If it has been found necessary to remove the head of the radius, permanent weakness may result: later osteo-arthritic changes are inevitable. In a child, when the head cannot be restored to perfect position, and yet its removal is considered unnecessary and inadvisable, a guarded prognosis should be given. The result may be good, but is often imperfect.

DISLOCATION

Dislocations in children as a rule do well, and even in adults the results are often surprisingly good. Each case, however, should be regarded as one of potential myositis ossificans and treated with the utmost gentleness after reduction. In dislocation of the radius alone, the results depend on the early course of the case. If dealt with promptly, and successfully, the reduction being apparently stable and easily maintained by simple flexion, all should be well. If, on the other hand, delay has occurred before reduction is attempted, or, when attempted, difficulties are encountered and, though apparently reduced, the head is unstable, and when perhaps a second anæsthetic is given for further efforts to be made, permanent impairment of function to a varying degree is certain to occur, particularly in adults. Periarticular calcification and ossification can occur with surprising rapidity in some of these cases.

COMMON FRACTURES IN ADULTS

In adults the common fractures involve the olecranon, the head of the radius, or the coronoid process. *Olecranon* fractures with displacement are treated as a rule by operation and give excellent results. The *probability of osteo-arthritic changes* depends largely on the operative skill of the surgeon. Even in elderly patients the results without operation and with movements commenced not later than four weeks after the fracture may be all that they require. Fractures of the *head and neck of the radius*, whether operation is deemed advisable or not, do fairly well if treated by early active movements and massage—i.e., as soon as the wound has healed if operated upon and sooner if not. Fractures of the *coronoid* probably result from "attempted dislocations"; the severity of the general damage to the joint and the degree of the resulting swelling determine the final result. The more severe the injury appears to be the greater the need for initial rest and extra care in restoring mobility. It is unwise in an adult to maintain flexion above a right angle for more than a fortnight.

LESS COMMON FRACTURES

Of the less common fractures, a *transverse juxta-articular fracture of the humerus* is always difficult to treat, since any attempt to move the elbow before union is firm only results in bending the callus and delaying the union. T and Y fractures should be treated by operation and, if possible, fixation of the fragments, so that movements may be commenced reasonably early. Much depends on the skill of the surgeon and the accuracy of the replacement. These are grave fractures and, on the whole, the results are far from perfect. Severe trauma to the elbow, even in the absence of clear evidence of fracture, may lead to the formation of loose bodies in the joint, with impairment of function and a varying degree of disability. This is more commonly seen in adults than in children. In some cases the capitellum is broken away and displaced forwards and upwards. Its prompt removal—it is rarely possible and wise to replace and fix it—leads to a fairly good early result, but eventually, as after removal of the radial head, it is certain to be marred by osteo-arthritis. In assessing the degree of disability likely to occur after a particular injury of the elbow-joint, the sex, occupations, and work of the patient should be given every consideration.

H. A. T. FAIRBANK, M.S., F.R.C.S.,
Senior Orthopædic Surgeon, King's College Hospital.

ROYAL SEA-BATHING HOSPITAL, MARGATE.—The report of this hospital for 1933 shows that the average daily number of occupied beds was 308, the same, within a minute fraction, as in the preceding year. The average cost per occupied bed was £117 10*s.* 11*d.*, as against £122 18*s.* 10*d.* in 1932. The medical superintendent, Dr. R. W. Armstrong, reports that the proportion of cases discharged as "quiescent" reached the satisfactory figure of 77 per cent. for those suffering from surgical tuberculosis, and 61 per cent. for the non-tuberculous. The latter group comprised a considerable number of cases which were not susceptible of cure. Last summer there were few days on which heliotherapy was unable to be practised. He adds: "There were long periods, however, when wind, which is ordinarily so characteristic of the climate of Thanet, was completely or almost completely absent, and it was noticeable that during these periods many patients tolerated sun-treatment relatively ill, and on the whole one rather formed the impression that less benefit accrued than in the more normal type of summer."

SPECIAL ARTICLES

BRITISH MEDICAL ASSOCIATION

MEETING IN BOURNEMOUTH

BOURNEMOUTH, according to its medical officer of health, Dr. H. Gordon Smith, is a place of peace[1]; for the young and active desiring stimulation and excitement, he adds, the district is not suitable. We do not dispute his dictum that "at certain times of the year it has a soothing effect," but last week, at any rate, it provided enough stimulation and excitement not only to satisfy the young but to rejuvenate the elders. The first two days of the Representative Meeting furnished ample controversial matter to enliven dinner tables over the week-end but, in fact, a sunny atmosphere prevailed on Sunday, which for the most part was spent out of doors in cars or boats, some private parties were arranged, the facilities offered by the Corporation of Poole at a new bathing centre at Branksome Chine being much appreciated. A large contingent accepted the same Corporation's invitation to lunch and a tour round the harbour on motor-boats. In the evening the famous municipal orchestra of Bournemouth, under Sir Dan Godfrey, gave a Wagner concert. During the first days of the following week the representatives, still hard at work, were gradually joined by visitors from "those two long, dull, parallel streets where, it is commonly believed, the waters of healing are laid on at the main." At the president's reception on Tuesday the guests filled the ballroom of the Pavilion, and also the huge concert hall, where music, a variety programme, and films were provided in turn for those who did not want to dance. Some had been up before nine that morning to attend the opening by the president of the exhibition of surgical instruments and appliances, food, drugs and books set out in the Winter Gardens; a far greater number were roused very early on Wednesday by the fear that they would be too far back in the queue to acquire tickets for the dinner and dance to be held on Friday at Southampton, on board *R.M.S. Aquitania*. The mornings of this and the two following days were taken up by the sectional meetings held at the Municipal College, in which the available accommodation had been nicely adjusted to the expected distribution of members. For the most part, estimates of attendance had been fairly accurate; on the first day only the debates on ante-natal care and on the use of narcotics in the treatment of nervous and mental patients (see p. 272) were held in somewhat over-crowded rooms, while larger ones appeared to be less well filled. The pathological museum, in the spacious basement, contained some interesting material, notably a "clinical picture gallery," mostly dermatological, exhibited by Dr. Watson Smith; the specimens and photographs of pancreatic and renal changes in mental patients lent by the Royal Bethlem Hospital; a series of malignant tumours experimentally produced by methylcholanthrene at the Research Institute of the Cancer Hospital (Free); and the exhibit of parasites, mostly tape worms, and capsules and cysts recovered from human muscle and brain, lent by the Royal Army Medical College, Millbank. Most of the sections concluded their discussions each morning in good time for lunch, and the afternoons were spent at garden parties in different parts of Hampshire and Dorset, in tours by land or by sea, or in recumbent posture on bed or beach in preparation for renewed activity at civic reception, Association dinner, or popular lecture in the evenings. The most flattering tribute to the efficiency of the secretariat of the Association, which is ultimately responsible for the organisation of these annual meetings, was the general acceptance of the good things offered to the mind and the body without comment, as part of the traditional hospitality of the British Medical Association.

PROCEEDINGS OF THE REPRESENTATIVE BODY

(Concluded from page 202)

The Staffing of Welfare Centres

THE provision of any pegs in the wall by which whole-time medical officers might "climb into the orchard of the general practitioner and steal his diminishing stock of fruit" was deprecated by Dr. B. H. PAIN (Tunbridge Wells) in connexion with the qualifications to be demanded of officers of welfare centres. Prof. R. M. PICKEN, as chairman of the public health committee had brought forward the motion that "it is desirable" that such officers "should have had experience in general practice." Manchester, in the person of Dr. A. Gregory, wished to strengthen this pronouncement by substituting the word "essential" for "desirable" and by specifying two years as the minimum period of such experience; while Newcastle wished to extend the period to three years. Dr. PAINE feared that insistence on this proviso would strengthen the influence of the full-time medical officer, who would be able to say: "I've been in general practice, and *I know*." Sir HENRY BRACKENBURY emphasised the danger of adopting a policy in conflict with the agreement embodied in the Askwith memorandum on salaries of whole-time officers in public health services. Under this memorandum a period of three years' professional experience "in the practice of his profession" was required of a candidate, not more than one of these years being spent in public health work as a temporary officer. Sir Henry held that it would be unwise to alter this arrangement while it was acceptable to those concerned as prospective employers and employees. Dr. E. H. T. NASH supported this view, and Prof. PICKEN pointed out that while a medical officer of a welfare centre should have some knowledge of conditions in the homes of the people, which could well be gained in general practice, insistence ln a prolonged experience would so extend the period of apprenticeship for public health work as to discourage men from attempting to enter a branch of medicine which held out no glittering prizes, even to its most successful votaries.

It was agreed to adopt the motion, leaving the time of experience in general practice unspecified.

The Use of Anæsthetics and Analgesics by Midwives

Prof. RALPH PICKEN drew attention to the action of the Council in informing the Ministry of Health and the Central Midwives Board that "it views with apprehension the proposed extension of the freedom of the midwife to administer drugs on her own responsibility, believing it to be dangerous and contrary to the public interest." Sir EWEN MACLEAN supported this action, on the grounds that the indiscriminate use of drugs by midwives would have serious results to the patient. It would lead not only to a rise in the forceps rate, but to difficulty in maintaining asepsis. A committee of the College of Obstetricians and Gynæcologists had been appointed to look into the question of the use of drugs by midwives; at the present time, influential persons were pressing for a relaxation of the rules in what Sir Ewen deemed an unwise fashion. Sir Henry Brackenbury said that the medical profession were not less anxious than the lay public that relief of pain in childbirth might be available for the poor as well as for the rich woman. Their opposition to the use of analgesic drugs by midwives on their own responsibility arose not from a jealous regard for their own emoluments, but from concern for the welfare of the patient. No administration of chloroform or ether could be made quite foolproof, and a full medical training should be required from those to be entrusted with their use. Possibly a new method of giving nitrous oxide, now under trial, might be made foolproof, under district as well as under hospital conditions; if the anæsthetic could be administered by the patient herself rather than by the midwife, the problem might be solved.

---

[1] The Book of Bournemouth. A series of 23 essays, richly illustrated, edited by Dr. S. Watson Smith. Bournemouth: Pardy and Sons. 1934. Pp. 212.

The section of the supplementary report on public health, in which the attitude of the council on this matter was made clear, was adopted.

The Law relating to Abortion

The question whether the council should itself initiate a general inquiry into the law relating to abortion or should merely express willingness to contribute expert medical assistance or evidence to any committee set up by the Government on this subject was eventually settled by the decision to set up a committee with a limited reference "to consider and report on the medical aspects of abortion."

Dr. J. W. Bone, as chairman of the public health committee, pointed out that the subject falls under two main heads: (1) therapeutic abortion, and (2) abortion used as a normal method of decreasing the number of births. With regard to (1) it had been said that some practitioners are unwilling to induce abortion on therapeutic grounds, because they are insufficiently protected by the existing law; the council of the Association did not believe either that practitioners failed in their duty in this respect or that protection was insufficient. With regard to (2), abortion was legalised in certain European countries, and in Soviet Russia it had been stated that 11,000 abortions had been performed in a year with no deaths and few cases of septic infection. It was the information that the mortality and morbidity associated with the operation were so much reduced when it was legalised that had attracted the attention of certain medical men to the legal position. The council took the view that this was a broad public issue rather than a purely medical one, and had thus put forward a restricted proposal for the appointment of a committee on the medical aspects of abortion. In the course of the discussion, it was said that democratic governments tend to shirk issues of this kind, and that a corporate body of 100 years standing could, and should, give guidance and help to form and educate public opinion. Dr. Parry, of Brighton, was not satisfied of the wisdom of setting up a committee unless the Government established an inquiry on broad lines, since the *medical* indications for abortion were already well known; Dr. Hawthorne agreed that these were clearly set out in text-books and appeared to be concerned lest the committee should venture too far afield in its deliberations and report. Dr. E. R. C. Walker held that the profession was concerned with the whole personality of the patient, not only with her physical condition; and Dr. J. S. Manson, for Warrington, obtained an assurance on behalf of the council that the forensic and preventive aspects of the subject would not be ignored. The suggestion that the matter might safely be left to obstetricians and gynæcologists was opposed by two prominent members of this specialty, Prof. James Young and Sir Ewen Maclean. The former held that difficulties arose in practice because the law was uncompromising in regard to penalties and yet left the circumstances under which action was permissible very vague. Sir Ewen Maclean regarded it as an important duty to ascertain whether this grave social menace was as prevalent in this country as had been suggested. He found it difficult to believe that the rough-and-ready methods of inducing abortion, said to be practised on a large scale in Russia, were really so free from mortality and morbidity as had been claimed.—Dr. E. W. G. Masterman held that a pronouncement, following investigation by the Association, was highly desirable; an appalling number of cases of abortions was received in municipal hospitals.

In spite of gloomy forebodings by Dr. Hawthorne the meeting eventually decided to set up a committee with the limited reference indicated above.

Secret Remedies

The publication many years ago of the book entitled "Secret Remedies" was described as one of the best pieces of work done by the Association, in a motion by Kensington pressing for its periodical re-issue. The proprietary remedies on the market had altered greatly since 1914, and there was a general demand for information as to their content. Sir Robert Bolam and Mr. Souttar pointed out the difficulties of the proposed task, which had to be approached with great caution, and the motion was accepted in a modified form.

The Direct Representatives

Speaking for Marylebone to a motion—

> That the council be requested to consider the arrangements under which the selection of candidates within the British Medical Association for nomination to the General Medical Council is at present conducted, with a view to removing if possible the objections which have been advanced against the existing practice—

Dr. B. Spurgin outlined the present procedure. A meeting of the profession was summoned in every divisional area to select by vote the candidate most approved; then in the town where the annual meeting was held a meeting of the representatives of the English and Welsh constituencies was summoned to make a final choice from among those nominated.

The principle underlying this procedure was that the Association would support the candidate favoured by the majority of the local professional meetings, but in this case no central meeting need be held, since the results of voting in each area could be sent by post to headquarters. If no such meeting had been held in any area, then the representative of the area had no right to vote. On the present plan the vote at the central meeting was taken by a ballot and there was thus no guarantee that the representatives did actually vote according to the opinion expressed by their divisions. One of the complaints, especially in the provinces, was that under the existing scheme no candidate had any chance unless he happened to be a prominent member of the B.M.A.; and again, that a candidate who wished to stand and had the support of his division was excluded from testing the feeling of the whole constituency.

It was sometimes said that the central meeting was not a meeting of representatives or of members of the Association, but of the whole profession, but a meeting open to the whole profession could hardly be called into existence at the particular town in which the B.M.A. annual meeting is held.

Dr. Hawthorne, supporting the amendment, said that no one doubted that under the existing scheme the best possible representation had been secured, or that the active interest taken by the Association in the election had given it a vitality previously lacking. It was sought only to regularise procedure by some means. On this understanding the motion was passed.

Miscellaneous Business

Many of the sections of the Council's report were adopted either with little comment or after discussion which led to no material results in amendment of motions, though often points of general interest emerged. For example, a motion by Dr. J. Cohen (for Kensington) that though separate sessions for contributing patients in V.D. clinics were open to objection, the principle of payment for services rendered should be encouraged, was lost, the meeting accepting the view expressed by Dr. Nash and Dr. Willoughby that to exact a fee from any patient would harm the work of the clinic.—The announcement by Dr. Le Fleming, as chairman of the relevant committee, that the Report on Nutrition had been an outstanding success, more than 12,000 copies having been sold, was received with enthusiasm. For the first time, he said, the calorie had been translated (1) into terms of food, and (2) into terms of money, and this could be reckoned a great achievement.—Mr. Bishop Harman's favourable report on the progress of the National Ophthalmic Treatment Board also caused general satisfaction. The memorandum of evidence tendered to the Departmental Committee on Health Services in Scotland by the Scottish committee of the Association was presented by Dr. J. B. Miller. The criticism that it should have been submitted to the divisions for approval was fully met by an explanation of the time factor, and no other major criticism of its provisions was offered. Dr. Walker's description of the document as a better exposition of B.M.A. policy than any hitherto issued was received with good-humoured applause.

THE ANNUAL DINNER

Dr. S. Watson Smith, the President, took the chair at the annual Dinner held on Thursday evening. Sir Crisp English proposed the health of the county borough of Bournemouth, expressing the appreciation of the Association of the hospitality it had received. There must, he said, be thousands and thousands of people who would gladly join in this toast in gratitude for the return of health. The Association wished him particularly to express its recognition of the coöperation that existed in Bournemouth between the authorities and the medical profession. He concluded with a tribute to Sir Dan Godfrey, the director of the municipal orchestra.—Alderman J. R. Edgecombe, mayor of Bournemouth, responded, attributing a great part of the popularity of the town to the recommendations of doctors in years gone by. The town had changed its character, from being a health resort only to being also a pleasure resort. It put the finishing touches to the healing work the medical man had started.

The Earl of Malmesbury proposed the health of the Association, which he described as one of the most important bodies in civilisation. Laymen recognised to the full the magnificent work that the Association was doing.—Sir Henry Brackenbury responded, observing that the reply to this toast was the last duty of a retiring chairman of council and offered congratulations to his successor, Dr. Kaye le Fleming. He expressed gratitude to the towns of Bournemouth, Poole, and Christchurch for their abundant generosity and kindness. There had been of recent years two special features of the Association's work: the number and wide extent of the overseas representation and the activities of the Association as a great social service. The Association was not only a great medical but also a great imperial concern. The interests of the profession were one and the same as the interests of the public. The health of the people had become increasingly a concern of the State and of the local authorities, but there were many overlapping interests and neglected opportunities. The Association had always been in the forefront of the communal concern for health. It was not unreasonable to expect the authorities to consult and use the medical profession. The services of the State, though preventive in aim, had become largely clinical in their expression. There were still some local authorities which had not been wise enough to accept the aid proffered by the Association which, he assured them, was proffered in no wish to gain more work and emoluments for its members, but in order that it might play its part in social service.

Dr. F. W. Broderick proposed the health of the Guests, to which Sir Henry Page-Croft, M.P., and Dr. D. M. Embleton (Melbourne) responded.

Dr. E. K. le Fleming proposed the health of the Chairman. He said that the local division, recently in a great difficulty, had followed scriptural advice to look to the hills for help, and had looked to Scotland, finding among themselves an exile from that land, bearing his lot with patience and fortitude. The position which the president-elect had been unanimously chosen to fill was no easy one; Dr. Watson Smith had already undertaken many tasks in connection with the annual meetings, including the publication of the "Book of Bournemouth." For the first time in its history, the Association proposed to carry the flag right round the world during the President's year of office. The hospital question, in which he took keen interest, was going to become of universal importance during the next few years.—The President, in reply, declared that he had not come South in search of gold, but of something far more valuable—viz., health. He had deliberately chosen Bournemouth to live in and later to work in.

ANNUAL GENERAL MEETING

The new president, Dr. S. Watson Smith, was formally inducted to the chair on July 24th at the 102nd annual general meeting of the Association. Prof. T. G. Moorhead, in investing him with his badge of office, referred to the sympathy felt for Mr. F. W. Ramsay, lately president-elect, who through ill-health found himself unable to proceed to the chair. At a moment critical for the Bournemouth meeting, he said, Dr. Watson Smith had stepped forward and guided the organisation with evident success. The incoming president spoke of the gifts of intellect, manner, and heart that his predecessor had brought to his year of office and, in reply to a vote of thanks moved by Sir He[illegible] Brackenbury—"not merely as an expression of th[illegible] to the president, but as a tribute to the man"—Dr. Moorhead referred to the help given him by his wife and the consideration shown him by the officers of the Association. He expressed his hope that, during the coming year, a much larger and more united medical organisation would be formed in Ireland than any now existing, and that it would be an integral part of the British Medical Association.

SECTION OF MEDICINE

Prof. W. LANGDON BROWN (Cambridge) presided over this section, and Dr. A. F. HURST (Windsor) opened a discussion upon

The Clinical Importance of Achlorhydria

Dr. Hurst said it was most important to determine how achlorhydria could be prevented or, failing this, how to cure the underlying condition instead of merely treating it symptomatically by means of artificial gastric juice. Referring to some fundamental facts concerning the physiology of the stomach, he said that protein digestion was carried on equally well in the intestine in the absence of pepsin and hydrochloric acid. The antiseptic action of the gastric juice was more important, since it protected against infection with bacteria present in food and drink. Dysentery and similar infections occurred much more commonly in people with achlorhydria or hypochlorhydria, and he was sure that the Services would save much invaliding if men with achlorhydria were not sent to the tropics. The diminished alkalinity of the intestinal contents following achlorhydria favoured extremely rapid ascending invasion with *B. coli* which are found in large numbers in the duodenum. Infection with streptococci from above and *B. coli* from below, together with mechanical irritation of the mucous membranes by insufficiently-softened and broken-up food might lead to chronic enteritis which was, therefore, frequently associated with achlorhydria. Reference was also made to the presence of hæmopoietin and neuropoietin in the gastric secretions. Most people with hyperchlorhydria suffered sooner or later from gastric or duodenal ulcer, while those with [illegible] developed achlorhydria. In both [illegible] result of chronic gastritis following irritation of the mucous membranes, either mechanical irritation (bolting food, or taking excess of coarse vegetable material), or chemical irritation (alcohol, especially on an empty stomach or mixed with other irritants in cocktails; strong tea or coffee; excess of condiments; drugs such as bromides, mercury, digitalis; or tobacco).

Chronic gastritis would also follow on excretion of toxins through gastric mucous membranes after acute infections. These causes were so universal that few with the hyposthenic or hypersthenic gastric constitution escaped. Achlorhydria was often familial but it was still uncertain whether it was ever congenital. The mucous membrane attempted to protect itself by the secretion of mucus which neutralised some of the acid but also blocked the mouths of the acid-secreting tubules. The inflammation of the mucosa depressed the functional activity of its glands—the more delicate oxyntic cells suffering first. Thus, in individuals with a hyposthenic gastric constitution, achlorhydria resulted, so that removal of the mucus by lavage would restore free acid in the gastric juice. Restoration of hydrochloric acid secretion even after the injection of histamine was impossible in some cases where there was severe chronic gastritis with achlorhydria associated with secondary bacterial invasion and progressive atrophy of glands leading to achylia. In these severe cases of true achylia, the production of hæmopoietin and neuropoietin was diminished sufficiently to give rise to Addison's anæmia and subacute combined degeneration. Dr. Hurst had seen three cases in which hydrochloric acid had returned following the treatment of the gastritis. After gastro-jejunostomy for duodenal ulcer, the acidity was partially reduced by alkaline duodenal secretions. When achlorhydria was present after such operation it was generally a sign that the operation had been needlessly performed on a patient with achlorhydria, or on one with chronic gastric ulcer in which hyperchlorhydria had been replaced by hypochlorhydria as a result of chronic gastritis. Although achlorhydria made it impossible for anastomotic ulcers to form, there might be chronic diarrhœa, cholecystitis, or simple achlorhydric anæmia, while a deficiency of hæmopoietin would allow development of Addison's anæmia. The complete achylia following removal of the entire stomach might lead to the onset of this anæmia owing to the loss of the glands producing hæmopoietin. Partial gastrectomy, however, might also be followed by simple achlorhydric anæmia.

Achlorhydria was present in some 65 per cent. of patients with cancer of the stomach. The achlorhydria was caused by chronic gastritis, and the growth was a result of malignant degeneration of the chronically inflamed mucous membrane. Carcinoma of the stomach might be seen associated with simple anæmia, Addison's anæmia, and subacute combined degeneration, which also were associated with chronic achlorhydric gastritis. Dr. Hurst had seen five such cases and John Wilkinson had recorded 22 others. He believed that with the prevention of recurrences of pernicious anæmia by modern treatment an increasing number of these cases would develop cancer. Cancer never developed in a healthy stomach, but in 25 per cent. of cases followed simple ulcer, and in 75 per cent. of cases followed chronically inflamed mucous membranes. It should be possible to prevent the development of cancer of the stomach by preventing chronic gastric ulcer and chronic gastritis, or recognising and overcoming them at an early stage. Gastritis should always be treated, and treatment would bring about the return of secretion of acid in 80 per cent. of these cases. Infection of teeth, tonsils and sinuses must be overcome; milky feeds were advisable at the beginning of treatment with omission of alcohol and tobacco, followed late[illegible] diet. Stomach lavage should be [illegible] no more mucus came away; thereafter less frequently. Hydrochloric acid and pepsin should be given to those in whom achlorhydria persisted. The disappearance of gastric cancer would depend upon the prevention [illegible] gastritis.

DISCUSSION

Dr. K. SIMPSON (London) consi[illegible] certain fallacies associated with gastric histology, holding that it was impossible to estimate secretory function from a histological examination of post-mortem material. The character of the mucus secreted was important, only certain forms being capable of neutralising hydrochloric acid. Gastritis of the recoverable type was of a more superficial character; when it extended to the deeper parts of the mucosa recovery was not to be expected.

Dr. JOHN F. WILKINSON (Manchester) referred to the effect of histamine in stimulating the production of free acid in the gastric juice in cases of apparent achlorhydria; for that reason its use was often of value for the detection of true achlorhydria, the pure gastric secretion removed at ten-minute intervals being examined before and after the injection of histamine. He did not agree with the suggestion that histamine stimulated only free acid secretion and had little influence on the enzymes secretion, for the output of the latter was also increased along with the acid. The gastric enzymes played a greater part than did the acid in the prevention of certain diseases, particularly hæmopoietin (the anti-anæmic enzyme) and pepsin. True achlorhydria was most commonly associated with pernicious anæmia and gastric carcinoma, but it was also frequently found in many other conditions. There was considerable evidence that it was not only familial, but might be unassociated with signs or symptoms.

Achlorhydria was frequently associated with symptoms referable to the gastro-intestinal tract; thus flatulence might be present for years, vomiting was uncommon, and nausea and heartburn might be troublesome. Chronic diarrhœa might be associated with flatulent dyspepsia or even epigastric pain. In a series of 135 cases suffering from chronic diarrhœa 43 (32 per cent.) had achlorhydria and 41 (30 per cent.) hypoacidity, making a total of 62 per cent. with secretory dysfunction. The cause of the diarrhœa in these cases was uncertain, but the immediate improvement following the administration of hydrochloric acid was very striking. Soreness of the tongue, often with ulceration, was commonly associated with anacidity, but a few cases might show hyperacidity. In a group of 47 cases 12 (25·5 per cent.) had achlorhydria and 17 (36·2 per cent.) hypoacidity—showing gastric dysfunction in 62 per cent. of the cases. The importance of treating these cases of achlorhydria must not be neglected, said Dr. Wilkinson, since he had seen gastric carcinoma or pernicious anæmia occasionally develop in them; an examination of the case histories in pernicious anæmia often disclosed that the first symptom had been sore tongue or diarrhœa. In pernicious anæmia, achylia was practically essential for correct diagnosis, and it had been almost invariably present in his series of 554 cases. Occasionally cases resembling pernicious anæmia had been seen with free acid in the gastric juice. Many of these were "hæmolytic anæmias" of pregnancy (with good prognosis). Others presented difficulties, and were undoubtedly hæmolytic anæmias quite distinct from pernicious anæmia; in these repeated blood transfusions formed the best measure but was only of a temporary value, for the prognosis was poor. The extreme rarity of pernicious anæmia (or subacute combined degeneration of the cord without anæmia) in the presence of free hydrochloric acid in the gastric juice called into question the correctness of the diagnosis in these cases. Recent work had shown that hæmopoietin was a more important constituent of gastric juice than free acid or pepsin. Hæmopoietin was present in normal gastric juice and normal human and animal mucosa; it was absent from the gastric juice and mucous membrane in pernicious anæmia and subacute combined cord degeneration. Interaction of hæmopoietin and the extrinsic food factor furnished the liver anti-anæmic principle which was present in normal liver but absent from the liver of relapsing pernicious anæmia. Achylia always preceded the onset of pernicious anæmia, and the latter followed the complete destruction of the gastric mucosa, either by chemical agents, gastrectomy, or gastroenterostomy.

He had records of 160 families containing two or more members with pernicious anæmia, nearly 70 families showing pernicious anæmia and achlorhydria in different members, and a further 30 families showing familial achlorhydria without anæmia. He discussed the association of achlorhydria and microcytic anæmia, referring to the close relationship between microcytic and macrocytic anæmias with achlorhydria and the conversion of one into the other. These changes were particularly liable to take place after gastric operation, for the hæmopoietic system being unstable reacted excessively to anti-anæmic treatment. He indicated the very marked familial tendency in microcytic anæmia, and also drew attention to the occurrence of pernicious anæmia when chronic intestinal obstruction was associated with achlorhydria. In 554 cases of pernicious anæmia two had developed gastric cancer and two carcinomata of the colon.

Dr. C. C. **Ungley** (Newcastle-on-Tyne) said that yeast owed its effect in pernicious anæmia to the extrinsic factor (Castle). Some cases of histamine-refactory achlorhydria with pernicious anæmia retained to a variable extent their ability to secrete intrinsic factor; thus a hæmopoietic response to yeast was an indication of this functional ability on the part of the stomach. The evidence pointing to a separate neuropoietic substance was based upon (i) the lack of parallelism in incidence, course, and response to treatment between the anæmia and subacute combined cord degeneration; (ii) the rarity of this neurological condition in tropical pernicious anæmia where factors other than gastric defect played a large part; such cases often had free acid which was almost never found in true subacute combined degeneration; (iii) the high incidence of nerve involvement in pernicious anæmia associated with extensive gastric lesions; in nine cases of polyposis there were six with pernicious anæmia, four having neurological symptoms; (iv) the dietaries of cases of pernicious anæmia with and without subacute combined degeneration failed to show extrinsic differences in the two groups, and, judged by the yeast response, intrinsic differences (hæmopoietin, chlorides, pepsin) in the gastric secretory functions.

Some cases of nutritional (idiopathic) hypochromic anæmia with achlorhydria showed moderate pepsin values, and about half could secrete neutral red in the gastric juice; in many the ability to secrete pepsin, chlorides, and neutral red resembled that in pernicious anæmia. The lack of the substance produced by the action of gastric juice on meat, spinach, and yeast might cause defective absorption of food iron, and symptoms such as sore tongue, dysphagia, koilonychia, easy bruising.

Dr. J. H. **Anderson** (Ruthin) referred to the association of achlorhydria with large numbers of diseases, and said that it was important not to think of this condition only in terms of cancer of the stomach or pernicious anæmia. He had seen 20 cases of complete achlorhydria in a consecutive series of 225 fractional test-meals. The achlorhydria occurred equally in both sexes, the majority in early middle life. More than half the patients were abstainers from alcohol and tobacco, or used these drugs sparingly. The most prominent symptom could not be correlated directly with the stomach, although 17 had some digestive disability of which flatulence, lack of appetite, and nausea supplied more than half. The illnesses had varied in duration from 6 months to 36 years, and in half the cases childhood and adolescence had not been healthy. Chronic infections were frequent, but in only two did an acute infection usher in the present bad health. The diagnosis on which treatment was based did not in many cases bear directly on the stomach. Glossitis was rare, the blood picture was often normal, or showed a simple secondary anæmia, and except in a few cases the rate of emptying of the stomach was unaltered. Constipation was a usual feature, and two of the three cases of diarrhœa could be explained by other than gastric causes.

He considered that gastritis could be recognised by careful radiography with the aid of good profile and strial pictures. It was present in 11 out of 14 cases. Further research was necessary into the incidence of achlorhydria in a large number of healthy young people with adequate controls with a follow-up of their medical histories for at least a generation.

Dr. **Gillespie** referred to the antiseptic action of the stomach secretions, and said that in China he had found it particularly useful to give hydrochloric acid as a prophylactic during epidemics of cholera.

Dr. G. W. **Goodhart** (London) said it was important to remember that the stomach possessed a muscular wall in addition to a mucous membrane, and that the character of the stomach contents would vary with the rate and quality of the gastric secretion, the addition of food, the rate of emptying, and the degree of regurgitation. He did not think that Dr. Hurst was consistent when he considered that mucus was a sign of gastritis, but did not indicate an inflammatory condition of the colon; gastric lavage was really a method of resting the stomach, and thus enabled it to regain its normal functions. In the majority of cases in which gastro-enterostomy was carried out a previously good secretion of hydrochloric acid was followed by achlorhydria; when the acid returned at a later date in some of these cases the symptoms also returned. Dr. Goodhart quite agreed that there were two forms of mucus, but did not think that they could be distinguished at the present time. It appeared possible that these were secreted in different parts of the stomach. No amount of mucus would neutralise the acid in a freely-secreting hyperacidic stomach. He could not believe that mucus prevented acid secretion by blocking the ducts, otherwise what would happen to the strong acid thus held back? He thought the best way of investigating gastric secretory function was to give the ordinary gruel test-meal followed at the end of one hour by histamine, so as to get some idea of the motor functions of the stomach. He also commented upon the difficulty of reporting cases of anæmia adequately in the medical journals.

Dr. **Alison Macbeth** (London) asked whether there was any evidence for the existence of neuropoietin in addition to hæmopoietin, and considered that it might only be a difference of individual susceptibility to one and the same deficiency. She also wished to know whether there was any evidence as to the nature of the substance in yeast described by Dr. Ungley.

Dr. **Dorothy Hare** (London) asked whether any value could be attached to estimations of the volume of gastric juice secreted after histamine in differentiating achlorhydria and achylia.

REPLY

Dr. **Hurst** (replying) said that mucus in the stools showed not colitis but a normal response to irritation by hard fæces; on the other hand, a test-meal was not an irritant, therefore mucus in the stomach meant gastritis and was pathological. He had some difficulty in explaining how the mucus caused a diminution of acid secretion, but it must act chemically or mechanically—the acid was produced under very low pressure so that blockage of the tubules would readily prevent its production. He could not believe that regurgitation had anything to do with achlorhydria. Flatulence was a genuine symptom of achlorhydria, the latter being the commonest cause of chronic diarrhœa. He agreed with Dr. Wilkinson that diarrhœa and sore tongue were extremely important symptoms requiring serious attention.

Dr. **Ungley** did not think that the yeast principle was similar to the liver principle since it differed slightly in its clinical behaviour.

Dr. **Wilkinson** agreed that the fractional gruel test-meal was the most useful clinically but histamine was often of great value. It was not possible to differentiate between achlorhydria and achylia from the ten-minute volume of the secretion. Hypo-acidity was also familial, and therefore might be a precursor of achlorhydria.

SECTION OF SURGERY

Mr. **Grey Turner** (Newcastle-upon-Tyne) presided, when Mr. G. **Gordon Taylor** (London) opened a discussion on

Bad Surgical Risks

Quoting Mr. Basil Rooke's definition of a bad surgical risk as "a type of patient whose prospect of recovery from active surgical interference falls much below the average," he said the focus of the discussion was on the patient rather than on the operation; there was, therefore, no intention of discussing heroic and formidable operative procedures such as excision of the thoracic œsophagus or of large hepatic adenomata, extraction of emboli from the pulmonary artery, or such attainments as that of Pierre Duval in extracting a bullet from the pericardial portion of the inferior vena cava. He was, he said, in agreement with the accepted view that extensive operations were more than usually hazardous when performed on members of the Jewish race. He did not think it was possible for a Jew to recover from an abdomino-perineal resection of the rectum, and he considered it unusual for him to survive gastrectomy for carcinoma of the stomach. Indians he had found to be bad surgical risks; but the Chinese stood operation well, and, contrary to the accepted view, his war experience had led him to regard the Irish as good subjects for operation. A long-lived ancestry must be looked on as a great asset when surgery was contemplated. Certain operations, such as extirpation of the rectum by the combined method, were better borne by women than by men. Women, on the other hand, were more liable to anæmia following gastrectomy than were men. An important point to be borne in mind was the disastrous result that might follow the performance of a radical breast operation during the menstrual period. There was more risk attached to operations performed at the extremes of life than to those performed in the prime of life. It must be allowed, however, that operations in the first three months of life, if carried out by skilled and experienced surgeons, were characterised by a remarkable degree of safety. Rammstedt's operation for pyloric stenosis and herniotomy (when considered essential at this early age) were absolutely safe in competent hands. In emergency operations in the first few days of life, the danger was related rather to the serious nature of the condition calling for operation than to the age of the infant. The prognosis in non-gangrenous intussusception was excellent, despite its occurrence in 50 per cent. of cases between the fifth and ninth months of life. Injury and severe operation were ill-borne by the aged, but he had successfully performed colostomy for cancer of the rectum in a woman of 98 years, and he had resected under light general anæsthesia, a carnoma of the transverse colon in a man of 85, who was alive six years after.

Obesity greatly increased the mechanical difficulties of operation, both on account of the depth of the wound and because of the presence of subperitoneal fat. The likelihood of a deposit of fat around the heart must be kept in mind, and the fact that these patients were more liable to suffer from chest complications and from emboli. He thought it was wise, where there was no special urgency in the case, to spend time deliberately in reducing weight before attempting operation. A few days spent in bed were of value, and might decrease the pain experienced. Excess in alcohol and tobacco increased the risk of surgical procedures. Antecedent and intercurrent diseases were serious handicaps, especially when latent or unsuspected. He had seen pulmonary tuberculosis flare up in patients apparently recovering from perforation of a gastric ulcer. Even very definite cardiovascular degeneration did not preclude the possibility of recovery from major surgery. A low blood-pressure was a more serious handicap than was hypertension. Renal disease was a serious drawback, particularly in genito-urinary surgery. Insulin and glucose therapy had now rendered the risks of operation in diabetes almost negligible. Antecedent infections constituted a definite danger. It was known that erysipelas might recur during the convalescence of a patient who had suffered from it in the past. Recrudescence of tetanus might occur in reopening a wound infected years before; he had seen a most alarming flare up of a streptococcal infection after an operation for diaphragmatic hernia by the transthoracic route, caused by a gunshot wound ten years previously. Operation should not be undertaken in those who had recently suffered from colds, influenza or pneumonia; it was wise to allow months to elapse.

The "psychological undesirables" presented much anxiety. He would advise surgeons to avoid, if possible, operation on patients who needed persuasion and over-persuasion, and to view with alarm the sight of stacks of books at each side of the bed, more particularly if they were French novels. Other danger signals were the reading of the paper upside down, and delaying the theatre in order to put the last few lines to an autobiography. Patients, usually women, who changed their religion the night before an operation usually died. Loquacity often heralded surgical disaster.

Surgical risks were at a minimum in operations on the pelvis, which might almost be said to be the surgeon's playground. The surgery of thyro-toxicosis was at one time one of the most dangerous of fields; the work of physician and biochemist had now rendered it one of the safest. At the Middlesex Hospital the mortality rate for all cases of toxic goitre operated on by all the surgeons was under 1 per cent. Preoperative administration of iodine and repeated investigation of the basal metabolic rate had reduced the surgeon to a mere carpenter in the hands of the physician and biochemist, who seemed to know the exact hour at which operation would be best tolerated. In the field of gastric surgery a great deal of judgment was needed, there was danger of too much being attempted in a patient who would not stand it. Bleeding from a chronic ulcer at once converted a patient into a bad surgical risk, but he was, if anything, a worse medical risk, and after a second hæmorrhage the mortality without operation was about 78 per cent. The operative mortality, after a single hæmorrhage, in his own cases was 19 per cent. All gastric cancers were bad risks; whereas a patient who had had a gastrectomy done for ulcer would always try to live, if it had been done for cancer he would always die if he could. Almost every case required a transfusion of blood. The danger of post-operative thrombosis was increased when there was a high initial blood-platelet count. To minimise the danger of resections of the colon in difficult cases, and in patients who were considered bad risks, the Paul-Mikulicz type of operation should be employed more often. In his hands it carried a mortality of only 1–2 per cent. Drainage of the bowel, preliminary or simultaneous, the use of lateral incisions directly over the growth, and drainage of the abdomen at the site of the anastomosis also made for safety. In cancer of the tongue or mouth radium therapy now provided an alternative to operation.

In conclusion Mr. Gordon Taylor expressed his opinion that the development of the craftsmanship of surgery was not yet finished, and that bad risks of to-day might well become the certainties of to-morrow.

Mr. ERNEST MILES (London) said that with few exceptions the minor operations on the rectum carried no risk. But in operations for piles there was risk when excessive bleeding had led to progressive anæmia; in the patient with cirrhosis of the liver, when "stopping the leak" might lead to post-operative hæmorrhage, and where bleeding from piles was a symptom of high blood-pressure apoplexy might result from stopping it. In operating for fistula it had to be remembered that in 14 per cent. of cases the origin was tuberculous and repair might not occur. The apparently very severe operation of rectosigmoidostomy for complete anal prolapse rather surprisingly showed no mortality and was followed by perfect healing. Cancer of the rectum he regarded as "public enemy No. 1." Since without operation the condition was always fatal in two to four years, operation had to be attempted and the surgeon must put up with the material supplied to him. In the days of inhalation anæsthesia he had been wont to regard the patient over sixty as a poor risk. The fat patient was always a great problem, but the worst risk was the patient who had suffered from prolonged and severe constipation in the presence of a foul and necrotic ulcer, and had a marked degree of toxæmia. At least a week's preparation was then essential, consisting of daily enemeta, and repeated wash-outs. Where there was definite obstruction at the rectosigmoidal junction it was wise to do a cæcostomy (his own choice) or a colostomy in continuity, without division of the bowel, as a prelininary procedure.

Mr. ERNEST FINCH (Sheffield) said that to the question what was meant by "poor resistance" there was at present no satisfactory answer; he felt confident it was only a matter of time until physiology supplied one. One of the most important factors, he thought, was fluid circulation in the body. As pointing to danger in delay, he cited visible peristalsis in the case of pyloric stenosis, and dribbling urine in enlargement of the prostate. He had been particularly struck with the high mortality attaching to operations for empyema. As regards patients with cardiac lesions, it should be realised that, whatever else surgery might be responsible for, it did not cause decompensation. There was as yet no real test of liver efficiency, and we still met with unexpected fourth and fifth day deaths from failure of liver function. He looked on prostatic cases as amongst the worst risks; in Sheffield practically all the cases reached the hospital in the stage of acute retention. The catheter he regarded as the curse of prostatectomy. He pointed out that although hæmorrhage from a gastric ulcer was an indication for operation, this was not the same thing as saying that hæmatemesis was an indication for operation. He considered blood transfusion more valuable as a pre-operative than as a post-operative measure. He strongly advocated the Paul-Mikulicz type of operation in cancer of the colon in certain difficult cases; it was better, in the words of Frank Jeans, to have "a living problem than a dead certainty."

Mr. MAX DANZIS (Newark, N.J.), from his experience in a hospital in which 60 per cent. of the patients were Jews, was convinced that no greater risks were encountered in operating on Jews than on the rest of the population.

Mr. MCADAM ECCLES (London) thought it was probably the Continental Jew who constituted such a particularly bad risk. The English Jew, possibly because he was not under fear, was a better subject for operation. A preceding bout of insomnia in a patient normally accustomed to long hours of sleep formed a particularly unfavourable preparation for surgical procedures. He had also noticed that bad sailors, and bad travellers in general, took anæsthetics badly.

Dr. BERGSTROM (Sweden) said he considered one of the most important points was not to be in a hurry to operate. The heart should be treated if necessary, and time taken to X ray the lungs and test the kidney function. In prostatectomy he employed catheter drainage, was careful to ensure adequate hæmostasis and used a very large tube. In gall-bladder cases which had to be opened when they were acutely ill he employed regional and intercostal anæsthesia only.

Mr. JAMES RUSSELL (Glasgow) said he regarded as dangerous adrenaline in conjunction with local anæsthetics. It was wise to pay attention to the judgment of the ward sister in deciding when a patient was ready for operation.

Mr. E. W. G. MASTERMAN (London), from experience in Palestine, said there was no doubt that the Eastern Jew was a much worse subject for operation than was the Arab. He had operated on a girl with diabetes, under treatment and free from glycosuria. The appendix had been removed under cocaine anæsthesia, with the result that after 48 hours she had gone into a fatal coma.

Mr. R. L. SPITTEL (Colombo) said that from his experience of Indians the normal individual in his normal environment, if well-fed, constituted no worse risk for operation than members of other races.

Mr. R. B. BLAIR (Hull) thought the nervous patient was often a most satisfactory person on whom to operate, once his confidence had been obtained.

Dr. W. N. LEAK (Winsford) had come to the conclusion that the condition of surgical shock was an avitaminatosis due to failure in storage of vitamin A in the liver. He had obtained encouraging results by injecting this vitamin in post-operative cases.

Mr. BASIL ROOK (Bournemouth) said he was impressed with the psychological factor. The Norfolk labourer did not seem to suffer from shock. The person of high mentality was a worse risk than the person of low mentality. He had found the professional man, even when in the prime of life, a bad patient, because he worried about his work. The fat cheerful type of patient reacted favourably to operation.

Mr. GORDON TAYLOR, in reply, agreed with Mr. Miles about the value of preliminary cæcostomy. One of the most valuable aids to the surgeon was the coöperation of the anæsthetist.

SECTION OF NEUROLOGY, PSYCHOLOGICAL MEDICINE, AND MENTAL DISEASES

Dr. LIONEL A. WEATHERLY (Bournemouth) presided over this section and asked speakers to confine themselves to the use of hypnotics, for their abuse did not imply any inherent fault in the drugs themselves.

A discussion was then opened by Lord HORDER on the

Use of Narcotics in the Treatment of Nervous and Mental Patients

Lord Horder said that it was convenient to make a distinction between pain killers and sleep producers. The two groups overlapped; all narcotics were also hypnotics, but all hypnotics were not necessarily narcotics. If the cause of sleeplessness was pain then even mild doses of narcotics, by allaying pain, might induce sleep indirectly rather than directly. The key to the successful treatment of insomnia, he said, was to find its cause or causes. Psychical causes had been called "primary"; these included anxiety (i.e., mental pain) in various forms, especially anxiety about not sleeping; and also the emotions of joy, sorrow, fear, love, anger, remorse. These required psychological treatment. The attitude of the patient towards sleep was extremely important, especially the fear lest want of sleep should cause permanent harm. Most people slept more than was necessary, and this should be made clear in reassuring the patient. Over-stimulation of the mind might be a cause of insomnia. It was necessary to inquire as to the manner in which the patient spent the latter part of the day. Over-fatigue of the body generally might be another factor. Dyspepsia in various forms, fever, usually associated with toxæmia, circulatory and respiratory lesions, the psychoses, excited and depressive states, all these, either separately or in combination might be the causes of sleeplessness. In regard to remedies, it was advisable first of all to consider all possible general measures. The next line of approach was by way of drugs; alkalis, salicylates and aspirin, the bromides, valerian, pyramidon. The place of alcohol as a hypnotic must also be considered, and its obvious risks taken into account. A night-cap at bed time was often helpful. Opium and its derivatives were indicated in certain cases where sleeplessness was due to severe pain. Hyoscine and the older hypnotics had long been used for the relief of insomnia and to allay mental excitement. The newer group of hypnotics—the barbiturates—marked a great advance because of exactness of dosage and constancy of effect. The ideal hypnotic, unfortunately, did not exist. It was not the drug but the development of a drug-habit that called for condemnation. This was equally applicable to tobacco and to alcohol, to tea and to cocaine. Sedative drugs formed a means of escape from life and its troubles. Sleep itself was a form of escape from life. Lord Horder urged the necessity of adopting a scheme of dosage for each patient. Sedatives were not necessarily best taken at bed-time. He was convinced that the ill effects attributed to hypnotics were considerably exaggerated.

DISCUSSION

Dr. R. CUNYNGHAM BROWN stated that he had helped in working out the results of an inquiry, which the Board of Control for some years sent out to the medical officers in charge of mental hospitals as to the amount and kind of sedatives used and their equency of administration. The Board reported at there was a great variation in the kind and mount of sedatives used, and that it seemed clear at the order and tranquillity of mental hospitals ad little relation to the extent to which sedatives ere used. A further report was still in preparation. His own views on the employment of sedative drugs vas that they had a valuable place in treating mental atients to relieve feelings of anxiety and distress; o alleviate excitement; to reduce violence; and, comparatively infrequently, as pure hypnotics. Insomnia per se seldom arose in mental hospitals or among psycho-neurotics.

Dr. JAMES COLLIER (London) confined his remarks to the actual effect on the nervous system of the barbiturates, which he describes as most valuable remedies. They tended to concentrate in the cerebro-spinal fluid and thus acted specially upon the nervous system. Removal of cerebro-spinal fluid most effectively relieved cases of barbiturate poisoning. Their earliest and chief effect was upon oculomotor mechanisms in the mid-brain and upon the region of the third ventricle, including the sleep region, and the temperature regulating mechanism, and upon the red nucleus which was really a part of the cerebellum. In some cases poisoning occurred without over dosage, probably due to abnormal retention; symptoms might suggest tumour of the quadrigeminal region. He considered the barbiturates safe and valuable drugs and had not found any ill results from controlled medicinal administration. They might, however, be very dangerous where vitality was low and oxidation processes slow, and would therefore be absolutely contra-indicated in pneumonia.

Dr. HAROLD SIMMONS (Bournemouth) stated that from the point of view of general practice, the relief of immediate symptoms was a preliminary necessity. Hypnotics were therefore often necessary as a first-aid measure. The need for hypnotics ranged from immediate relief of asthma by ephedrine or aspirin to the relief of mental fatigue, mental distress and insomnia which formed a large part of general practice; they were needed for the treatment of physical pain and for the production of basal narcosis. For nerve-racked patients he used bromide combined with some tasteless form of valerian, often replaced by small doses of luminal or chloralamide. In most cases, however, barbiturate was usually necessary to produce sleep. It must be realised that to rely upon hypnotics without seeking out and treating the condition underlying the demand for them was asking for trouble. The doctor's place as confidant often enabled great psychological help to be given by a general practitioner. In 35 years' experience, Dr. Simmons had never seen a case of habitual addiction following the use of barbiturates. Recently he had cured a case of persistent hiccough of cardiac origin by a combination of belladonna and phenobarbitual known as Belladenal.

Dr. MARGARET VIVIAN (Bournemouth) stated that her experiences in her own nursing home for mental patients was that narcotics should be regarded as emergency measures and not as remedies likely to lead to cure. Of all forms of restraint drug restraint was the least desirable. Administration of narcotics over a long period was a confession of failure to discover the cause of the symptoms demanding such treatment. Patients suffering from serious insomnia were never easy to deal with. Drug addicts suffering from withdrawal symptons were also a very grave problem. Dr. Modinos, the physician in charge of the European hospital in Alexandria, had been treating many cases of rheumatism by auto-sero-therapy—i.e., he blistered the patient and re-injected the blister fluid. One day a patient who wished to be treated for rheumatism proved to be a cocaine addict, and to the doctor's surprise, he found that after three injections of the blister fluid, the patient neither needed nor desired the drug. There were many drug addicts in Egypt, and Dr. Modinos decided to try his blister fluid on all those who sought his help. In a communication to the Paris Academy of Medicine he had described the treatment of eight typical cases, including patients addicted to morphine, heroin, cocaine and hashish. From two to five injections of the blister fluid sufficed to cure them all of any need or desire for their drugs. The word "cured" meant that the patient no longer needed or desired his drug. If he relapsed, he did so deliberately and no power on earth would prevent that type of fool from reverting to his folly. So far, she had tried this method on only one case, but the result was astonishing. The patient was a doctor, who had been taking up to 3½ grs. of morphia for nearly three years. He was anxious to be cured, but had failed to cure himself. After the first blister fluid injection, his daily dose was comfortably reduced to 1 gr. in the 24 hours. The second injection produced the most surprising result, the morphine being discontinued without any of the usual distressing withdrawal symptoms. A third injection, as Dr. Modinos usually gave, had caused mild protein shock, which hindered complete recovery, but the patient was able to go home at the end of the third week, and he assured her that he had no craving for morphia.

Dr. EDGAR MARTIN (Salisbury) said that although narcotics multiplied, sufferers from mental illness, like the toll of the road, went on increasing. It was not the drug that was to be blamed, but the use made of it. Each patient must be considered individually and the narcotics carefully chosen to suit individual needs. Doctors should not permit themselves to be dominated by outworn opinions and customs, but should have the courage of their convictions and experience.

Dr. R. EAGER (Exminster Mental Hospital, Devon) spoke of the lack of available guidance in the use of narcotics and the tendency to their indiscriminate use. Paraldehyde, for example, was given in mental hospitals in this country, because it was regarded as safe and not habit forming; its excretion through the lungs, however, made it a dangerous irritant of the mucous membrane. It was given far too often without respect to the individual. The use of alcohol as a nightcap was, as Lord Horder had said, of considerable value. Dr. Eager discussed the uses of various other narcotics in some detail, but in conclusion stressed the importantce of seeking the cause of symptoms rather than resorting to hypnotics. Attention to general health and the way in which the day was spent, and the wise use of occupation therapy, which was greatly encouraged in his own hospital, should go far to remove the necessity for the use of narcotics for mental patients.

Sir ROBERT ARMSTRONG JONES (London) spoke of the essential need for sleep and stressed the danger of noise to the nervous system.

Dr. T. A. WILLIAMS (Bordighera) referred to Pavlov's definition of sleep as an inhibition. It was a form of escape from metabolic tension which otherwise would lead to exhaustion. It was important to remember this when dealing with cases of insomnia. He stressed the psychological factor, especially anxiety as a cause of sleeplessness.

Dr. AGNES SAVILL (London) referred to treatment by the constant current which was started by Dr. Leduc. She had found it of great value in cases of mental strain and fatigue resulting from mental work. She thought that the use of music as a sedative had not been sufficiently considered.

Prof. W. S. DAWSON (*Australia*) spoke of the value of sedatives in the treatment of nervous children, especially by small doses of bromide and the barbiturates. He stressed the importance of a full inquiry into all the circumstances of the child's life. Psychological difficulties could not be cured by drugs alone. He spoke of the experiment in the treatment of dementia præcox by prolonged narcosis with somniphaine, which he had carried out with Dr. Mary Barkas at the Maudesley Hospital; the results had been very disappointing.

Dr. EDWARD MAPOTHER (London) said that he had tried morphia on depressed and melancholic patients with unsatisfactory results. He said that somniphaine was useful on account of its persistent effects, but that it had considerable danger when used to produce twilight sleep.

Dr. DORIS ODLUM spoke of the value of ammoniated tincture of valerian as an adjuvant to bromide, especially in the treatment of the psycho-neuroses. She had found that the ordinary B.P. drug was more effective than the proprietary odourless preparations.

REPLY

Lord HORDER, in summing up, agreed that the adolescent was better for too much sleep rather than too little, but after the age of 20, over-sleeping was nothing but a bad habit and represented an attempt to escape from the realities of life; it should be resisted strenuously. Daylight saving ought not to interfere with the sleep of children merely from the point of view of going to bed by daylight. Darkness ought not to be essential to sleep. In regard to Leduc's treatment by the galvanic current, he thought the effects might be largely attributed to suggestion, but if it succeeded in soothing the patients, it was by no means to be despised on this account. He agreed as to the value of valerian.

NOTES FROM INDIA

(FROM OUR OWN CORRESPONDENT)

THE INDIAN MEDICAL COUNCIL

THE Medical Council for India is now a *fait accompli*. The Act which brought it into being was passed through the Assembly only with difficulty and in the face of much unofficial opposition. It was hard to see what particular features of the Act were distasteful to the medico-political "left wing," but in these days anything that has official backing is accordingly suspect. The catch phrase used by the critics of the Act was "the dictation of the General Medical Council" or, alternatively, "of the British Medical Association" (they appeared to consider them synonymous). The Council is not a "packed" official body, but at the same time sufficiently responsible, we should imagine, to satisfy the General Medical Council whose "dictation" amounts to the suggestion that there shall be some central body in India with which they can deal and which, amongst other things, will be responsible for maintaining the standard of the examinations for the degrees that they, the General Medical Council, are asked to register in England.

The Council held one meeting early in the year, and another in June, and have now elected their inspectors of examinations, Dr. Farquhar Macrae, Sir Kedar Nath Das, and Dr. R. S. Tirodkar. A somewhat inauspicious incident marked the opening meetings. At the first meeting, apparently through a misapprehension as to the significance of the decision, it was agreed that members of the Council should not be eligible for election as inspectors of examinations and that this should apply to the secretary also. As the secretary was particularly chosen for his experience in inspecting examinations which no one else in India has had, the decision was very unfortunate; the subject was, therefore, reopened at the next meeting, and the decision, in so far as the secretary was concerned, was reversed. It seems a pity that the Government representatives on the Council, who were apparently able to carry their motion at the second meeting, did not take more trouble to do so at the first and thereby obviate a charge of irregular procedure.

EPIDEMICS AND INOCULATIONS

Cerebro-spinal fever appears to be getting a firm footing in India. Small outbreaks have been reported in jails and other institutions during the last few years, but this year minor epidemics of the disease in Bombay and Delhi have attracted a good deal of public notice. In Calcutta a steady incidence of about a hundred cases a month for over a year has apparently not stirred either the authorities or the public. Admittedly most of these have been sporadic cases, and it has not been possible to trace any focus of the disease. The central research institute at Kasauli have now prepared a serum from local strains and are issuing it for trial in hospitals in various towns in India. Practically all the provinces of India have now decentralised their anti-rabic treatment. Bengal was one of the last to fall into line. An interesting result has been a falling-off in the treatments given; this suggests that a number of patients came for treatment for the sake of the joy ride to Calcutta; for not only did they get a pass on the railways for themselves and their attendants but they also got a subsistence allowance in Calcutta. Cholera has been comparatively quiescent in India for some years, but this year it is showing signs of increasing in a number of places. Lucknow has recently been "in the news" on this account, the United Provinces reporting a thousand deaths a week from this disease. The health authorities are carrying out an extensive inoculation campaign. Now news comes of a sharp outbreak in the Simla Hills, following the return of a pilgrim from Hardwar to his native village; prompt action by the Punjab health department appears to have resulted in an early control of this epidemic.

MALARIA IN MONKEYS

The chance discovery, in the kala-azar research department of the Calcutta School of Tropical Medicine two years ago, of a scanty plasmodium infection in a *Silenus irus* monkey and its passage to a monkey of another species, *S. rhesus*, which then developed a fulminant and fatal infection, has led to an enormous amount of experimental work with monkey plasmodia, not only in India, but in Europe and America. In two recent papers in the *Indian Medical Gazette* the relative effects of quinine and Atebrin, administered by different routes, on monkey plasmodial infections have been shown. The action of quinine is slower than that of atebrin—this is demonstrated very dramatically in four photomicrographs—but with the latter drug the parasites reappear after about fifteen days, whereas with quinine, though a low grade of infection usually persists for some months, it seldom reaches the clinical level, and eventually without any further treatment it appears to die out. Another interesting point is that in the case of relapse following atebrin, one dose will usually control the infection and save the monkey's life. Intramuscular injections appear to be more efficacious than intravenous.

NKS BETWEEN LONDON HOSPITALS

LAST week we published news of a closer association ween the medical schools of St. Bartholomew's, y's, and St. Thomas's. Immediately afterwards a port was issued by the London Voluntary Hospitals mmittee (L.V.H.C.) which describes other associa- ons and agreements and shows that London's hospital eds are being envisaged as a whole.

This committee, whose chairman and secretary are spectively Lord Riddell and Prof. L. S. Dudgeon, .R.C.P., has been conferring with the hospitals and edical services committee of the London County ouncil, now presided over by Mr. Somerville Hastings, .R.C.S. At a meeting on June 7th Mr. Hastings romised that the L.V.H.C. would be told at the arliest possible moment of any proposed alterations nd extensions in the Council's service which were of ufficient magnitude and importance to interest the voluntary hospitals. He also said that his committee would be glad to discuss any such alterations with the L.V.H.C. This was in response to the suggestion of Lord Riddell, who, in reference to the fact that there were 96,000 beds in question, pointed out that "certain parts of the area seem to have no hospital accommodation at all; other parts are infested by hospitals." If the council thought the accommodation in any particular district was inadequate it might be well, he said, to agree on a joint plan of action and thus avoid future friction. He on his side promised that the arrangement should be mutual—that is to say, the L.V.H.C. will notify the London County Council of any important extensions or changes proposed by the voluntary hospitals.

An example of the efforts now being made to prevent overlapping was provided by a discussion on the extension of the out-patient department and receiving accommodation at the St. Andrew's (L.C.C.) Hospital at Bow.

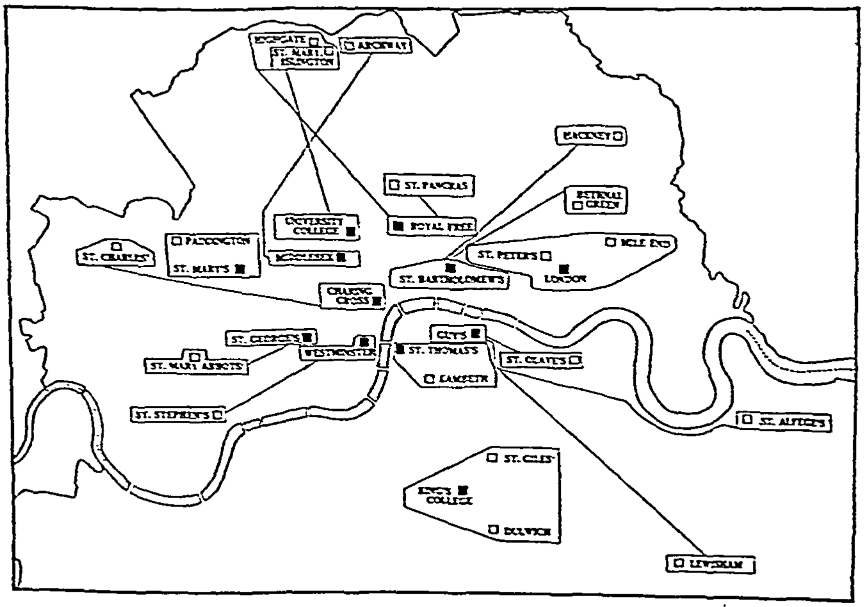
St. Andrew's is not far from the Poplar Hospital for Accidents, a voluntary hospital which has recently started to rebuild its out-patient department, and two representatives of the Poplar Hospital were present at the conference. The hospitals and medical services committee explained that there was no intention at this or any other L.C.C. hospital to provide a general out-patient department in the sense in which the term is used by voluntary hospitals, but merely to provide accommodation for the classes of cases (i.e., casualties, accidents, and other emergencies, antenatal and postnatal examination and treatment, after-care treatment for patients who had already been treated in the hospital, patients entitled to outdoor medical relief, &c., which may be admitted as out-patients to the Council's hospitals under a regulation made in 1931. The committee also pointed out that the areas from which most of the patients are drawn by the two institutions are materially different. The Poplar representatives were satisfied with this explanation and expressed their thanks to the chairman of the hospitals and medical services committee for the frank and friendly way in which they had been received.

The accompanying map shows the way in which the medical schools are now connected with municipal hospitals belonging to the L.C.C. The associations are as follows:—

Charing Cross	St. Charles'.
Guy's	Lewisham; St. Alfege's; St. Olave's.
King's College	St. Giles'; Dulwich;
London	St. Peter's; Mile End.
Middlesex	Archway.
Royal Free	Highgate: St. Mary, Islington; St. Pancras.
St. Bartholomew's	Hackney; Bethnal Green.
St. George's	St. Mary Abbot's.
St. Mary's	Paddington.
St. Thomas's	Lambeth.
University College	St. Mary, Islington.
Westminster	St. Stephen's.

As regards instruction in obstetrics special facilities have been provided by which students are allowed to reside for a fortnight at municipal hospitals, about ten cases being allotted to each of them during this period. Arrangements of this kind have been made between St. Thomas's and St. James's; the London and Mile End; St. George's and Lewisham: St. Bartholomew's and St. Giles's and St. Andrew's. It is hoped that facilities for this class of teaching will be extended.

Finally, mention must be made of the proposal to establish if possible a strong central committee to deal with the affairs of the London voluntary hospitals. It is felt that the London Voluntary Hospitals Committee covers too much of the same ground as the London regional committee of the British Hospitals Association, and a letter has been sent to King Edward's Hospital Fund for London recommending that "the voluntary hospitals should be represented by an elected executive body to take the place of the two existing bodies, and comprising adequate medical representation." The proposed committee is to be formed "with the object of promoting the efficiency



Sketch map illustrating the linking of medical schools (black squares) with L.C.C. hospitals (white squares).

of the service rendered to the public by the voluntary hospitals."

Both the present committees are elected by the hospitals, and they have, indeed, eight members in common. The British Hospitals Association Committee, however, has no medical representatives among its 33 members; whereas the 39 members of the L.V.H.C. include 21 doctors—namely, Mr. Bright Banister, Lady Barrett, Mr. L. E. Barrington-Ward, Mr. R. Davies-Colley, Prof. Dudgeon, Dr. Geoffrey Evans, Dr. Anthony Feiling, Dr. Hope Gosse, Dr. A. M. H. Gray, Sir Henry Jackson, M.P., Mr. J. P. Lockhart-Mummery, Dr. J. M. H. MacLeod, Mr. Robert Milne, Mr. Denham Pinnock, Dr. Eric Pritchard, Dr. Harold Pritchard, Mr. Cecil Rowntree, Dr. Bellingham Smith, Mr. T. G. Stevens, Dr. Hugh Thursfield, and Dr. C. M. Wilson.

MEDICINE AND THE LAW

Cross-infection at a Hospital: Negligence Claim Fails

An interesting dispute over standards of hospital technique came before the Privy Council last week on an appeal from British Columbia (Vancouver General Hospital *v.* McDaniel). Miss McDaniel, suffering from diphtheria, entered the Vancouver Infectious Diseases Hospital, and there (it was alleged) caught small-pox. In effect, the question was whether it was negligence not to isolate small-pox patients in a separate building staffed by separate nurses. The plaintiff, on the advice of her doctor, Dr. Kennedy, became a paying patient of the hospital on Jan. 17th, 1932; she was to be attended by the hospital nurses and by Dr. Kennedy. Vancouver was then encountering a small-pox epidemic. On the 18th a small-pox patient was placed in the room next that of the plaintiff; three days later another was placed in another adjoining room; a week later a third was placed in a room almost opposite, and the next day four more were placed in other rooms on the same floor. Miss McDaniel, being thus surrounded by small-pox patients, Dr. Kennedy asked that she be moved to another floor where there were no such patients and where a different set of nurses was in charge. This was done. On Feb. 3rd she was discharged cured of diphtheria and she went home; but within ten days afterwards she was found to be suffering from small-pox, which, when she sued the hospital for negligence, the hospital's legal advisers were willing to assume had been contracted by cross-infection. She claimed damages for this illness and for the consequent disfigurement and was awarded 5000 dollars in the Supreme Court of British Columbia, the judgment being affirmed in the local Court of Appeal.

The Privy Council came to the conclusion that no negligence was established; the award has therefore been upset and the hospital's appeal has succeeded. The plaintiff had said it was negligence (*a*) to put small-pox patients so close to her on the same floor, and (*b*) to let her be attended by nurses who were also attending small-pox patients. The hospital's answer was twofold. First, it claimed that its technique had been adopted on competent medical advice. Lord Alness, delivering the judgment of the Privy Council, thought this defence had not been definitely established; it was, however, proved that the technique had, in material particulars, been endorsed by every medical witness called by the hospital. The evidence of these witnesses had been unambiguous, and it has been contradicted by no one except Dr. Kennedy. The hospital's second line of defence was that its technique was in accord with approved modern practice. This issue was to some extent covered by the same evidence. Dr. Kennedy again was the main authority adduced for the plaintiff. "In spite," he said, "of recent teachings, he preferred the old system of isolating small-pox cases in a separate building, to the new system which, in effect, substituted sterilisation for isolation." The technique of the Vancouver Hospital was proved to be in vogue throughout the rest of Canada and in the United States, and no instance was given of a hospital not following the technique preferred by Dr. Kennedy. This being the state of the evidence, the Privy Council found it hard to affirm that negligence had been proved against the hospital in respect of the technique complained of. Dr. McEachern, responsible for an annual survey of 3464 hospitals in the United States and Canada, had said that the Vancouver Hospital's system was the best known to medical science to-day. The proximity of small-pox patients to other patients in an infectious diseases hospital, he said, was quite an accepted modern procedure in the modern method of handling infectious disease; so also was the use of a common nursing staff.

"A defendant charged with negligence," observed Lord Alness, "can clear his feet if he shows he has acted in accord with general and approved practice." In their lordships' opinion the Vancouver hospital had done so by a weight of evidence not to be ignored. The judicial members of the Privy Council were offering no opinion of their own on the merits of the unit system as distinguished from the isolation system in small-pox treatment; they merely decided that, in view of the evidence, the charge of negligence failed.

Protest Meeting against Hospital Report

The Vancouver case indicates that it is reasonable to take the view of medical authorities as to the proper conduct of a hospital. The popular view is not always the same. About 1500 people attended a meeting held in the Free Trade Hall at Manchester to demand a public inquiry into the death of Mrs. Taylor who, in circumstances described in THE LANCET of July 21st, died in Crumpsall Hospital after her removal from St. Mary's Hospital, Whitchurch-street, Manchester, where she had just given birth to a child. The facts appear in the report, summarised here last week, of a committee on which expert gynæcological opinion was well represented. Speakers at the meeting complained that a committee composed entirely of men could not appreciate Mrs. Taylor's mental stress at such a time, and that a committee consisting only of medical members could not be trusted to criticise the actions of doctors. There was a complaint that the whole truth had not been told in the report, and it was declared that Mrs. Taylor died of "an overdose of red tape." A motion for a public inquiry was carried with one dissentient, against whom there was some demonstration at the close of the meeting.

MIDDLESEX HOSPITAL.—Speaking last week at a special meeting of the court of governors of this hospital, in which he reviewed the story of the rebuilding, Prince Arthur of Connaught took the opportunity of replying to suggestions that the new nurses' home had set up an "almost luxurious standard." He pointed out that the anonymous donor intended to give something in the nature of a university status to women of high degree of education and training, and to provide the finest nurses' home in the world.

PANEL AND CONTRACT PRACTICE

Mortgaging the Practice

SEVERAL times recently public attention has been drawn (see THE LANCET, 1933, ii., 1324) to the position of practitioners tied hand and foot to money-lenders who have made advances for the purchase of a practice. Some of these young doctors have signed a blank form of resignation from the medical list as a condition of obtaining a loan, which means that they may at any time be evicted upon completion of this form by the money-lenders. There are cases in which panel practitioners have surrendered their practices and the first intimation to reach the insurance committee concerned has been a notification that the mortgagees have appointed a locum tenens to carry on pending the sale of the practice. Such appointments cannot be recognised, for in the event of complaints arising it may be impossible to trace the original practitioner who is of course responsible for the conduct of the practice until his resignation has been accepted by the committee and the patients properly transferred or given the option of being transferred to some other insurance practitioner on the committee's list. This trafficking in practices is on the increase—in London alone there are more than 200 cases in which fees have been assigned—and the Insurance Acts Committee and the National Association of Insurance Committees are considering their action. It was decided in a recent case (O'Driscoll and Another v. Manchester Insurance Committee) that the remuneration to which a practitioner who is on the medical list of an insurance committee is entitled is a debt which is capable of attachment and, this being so, is a *chose in action* and capable of assignment. The London Insurance Committee suggest an emendation of the National Health Insurance Act, 1924, somewhat on the lines of Section 21 of the Act which runs:

> "Every assignment of or charge on, and every agreement to assign or charge, any benefits shall be void, and, on the bankruptcy of any person entitled to any benefit, the benefit shall not pass to any trustee or other person acting on behalf of his creditors."

This would not prevent a practitioner entering into an agreement with a corporation or company to advance money for the purchase of a practice and instructing his banker to make appropriate periodical repayment. The committee say they have no desire to interfere with legitimate arrangements for the purchase of practices, realising that in many instances practitioners cannot buy at all without borrowing, but an insurance committee should not be forced into the position of agent for either party. A resolution in the sense of the emendation mentioned above is to be tabled for the coming annual meeting of the National Association of Insurance Committees. This will make void every assignment of or charge on any sum payable by an insurance committee to a medical practitioner in respect of medical benefit except for such purposes as may be agreed between accredited representatives of the medical profession and the Minister of Health. The resolution if passed will establish the broad principle, leaving the actual drafting to specialists.

Health Propaganda

While the main function of an insurance committee is to administer medical benefit to insured persons living within its area, it is also charged with the duty of health propaganda. Many committees are not in a sufficiently strong financial position to do much of this sort, others take it up in the form of lectures on "how to keep fit." When one remembers the amount of health literature sent out by M.O.H.'s, and published in newspapers, to say nothing of lectures by numberless health societies, the question arises whether there is any need for set lectures by practitioners. Do not the young people of to-day already tend to become neurotic over every little ache or pain? And is not this one of the contributing causes of so much sick pay amongst married women? Birmingham does not think so. Last year its insurance committee decided that a series of lectures on "How to Keep Fit" should be delivered during the autumn and winter by practitioners with over a thousand insured persons on their lists who had not lectured during the last five years. Notice was to be given by an explanatory letter addressed to the insured person enclosing an invitation card and a reply-paid postcard. Twenty such lectures were given, 41,444 invitations being sent out, and 4517 persons attended—an average of 10·9 per cent. of those invited. The attendance at a particular lecture varied from 376 to 100, and the cost from £18 14*s.* to £8 16*s.* The total cost of the lectures was £274, or 1*s.* 1½*d.* per person attending. Since 1925 when these lectures began, 250 have been given at a cost of £2913; the highest attendance was 19 per cent. in the first year, and the lowest 6·5 per cent. in 1930–31. Some people would doubt whether this expenditure produces results commensurate with the money spent. It will be noted that last winter at best only one person attended out of five invited, while the cheapest lecture cost nearly £9. It might be argued that if those who took the trouble to go to the lecture really wanted to know how to keep fit they could consult their own doctor.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Capts. C. V. Griffiths to *Victory* for R.N. Hospital, Haslar, and J. G. Danson to *President* for course.

Surg. Lts. S. R. G. Pimm to *Victory* for R.N.B., and H. de B. Kempthorne to *Victory* for R.N.B.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Sub-Lts. R. J. Carr and J. D. Spillane to be Surg. Lts.

ROYAL ARMY MEDICAL CORPS

Lt.-Col. L. G. Gibson retires on retd. pay.
Maj. J. B. A. Wigmore to be Lt.-Col.

ARMY DENTAL CORPS

Capt. J. L. Craig to be Maj.
Lt. F. J. McCarthy to be Capt.

TERRITORIAL ARMY

Lt.-Col. W. F. Denning resigns his commn. and retains his rank, with permission to wear the prescribed uniform.

General List.—Lt. D. L. Cran resigns his commn.

INDIAN MEDICAL SERVICE

Lt.-Col. A. W. Overbeck-Wright retires.

ROYAL AIR FORCE

Squadron Leader A. J. O. Wigmore is placed on the retired list on account of ill-health.

PUBLIC HEALTH

London Sewage and the River Thames

THE two most important tributaries of the River Thames are the great outfall sewers which discharge into it within a few miles of each other, at Barking on the north side and Crossness on the south. The treatment of these effluents has been the subject of a Royal Commission, and has continually occupied the attention of the Metropolitan Board of Works and its successor, the London County Council. The vastness of the problem has caused these bodies to walk warily, and, although experimental work has been undertaken on behalf of the Council by its officers, no material change in treatment has been effected since the system of sedimentation, either with or without the aid of chemical precipitants, was introduced in the last decade of the 19th century. It has however for some time been felt that further treatment of the increasing volume of effluent was necessary, and in a recent report to the Council the Fire Brigade and Main Drainage Committee note complaints about offensive smell from the river and suggest that it is the Council's duty without delay to improve things.

The activated sludge process had been tried on a small scale at the Crossness works, using a plant of rather special design in which the liquid to be treated was impelled by simple paddle wheels through long channels where its surface was exposed to the air and allowed to return through a lower channel. This was found to work extremely well and a much larger unit was authorised for the Barking outfall on similar but improved lines. After a sufficient amount of sludge had been prepared by aeration of successive volumes of settled sewage and conservation of the flocculent sediment thus produced the first large unit was put into commission in November, 1931. It was found that with volumes of sewage up to 8 million gallons a day an effluent was produced which could not possibly do any harm to the river, the maximum economy being obtained when treating 10 million gallons a day with from 7½ to 10 per cent. of activated sludge. Substantial economies have been effected by locating the re-aeration channels in a portion of the precipitation channels, thus taking advantage of existing works, and by the use of double compartment aeration channels. The Council have now decided to construct five additional units of similar capacity, which, with the existing plant, will enable rather more than one-third of the total dry-weather flow at Barking to be treated by this process. The estimated cost of the new plant, which will be spread over some years, is £520,000, apart from outlay on detritus pits and sludge digestion. The cost of running, including debt charges, is estimated at £40,000 a year, or a rate of about one-third of a penny.

These proposals, which seem to have attracted little public attention, are probably on a larger scale than anything before attempted; they are the end-result of long continued research, first on laboratory scale, through stages representing a small town and one of (say) 300,000 inhabitants. The new plant is based on the same principles as the old one-acre filter-bed at Barking which was the first attempt at biochemical treatment of sewage in this country. The essential agent being dispersed in the liquid to be treated as free humus the installation will be far more compact than one in which the agent is spread over a solid surface. The minor improvements mentioned should aid in sedimentation of the sewage before treatment by sludge, should reduce the amount of foul sludge which has to be dumped in the sea, and yield a useful source of power from the gases of fermentation. Substantial improvement may be expected in the summer condition of the Thames in the metropolitan reaches. Is it too much to hope that salmon will again consent to breed in the upper reaches?

Port Medical Service

A new edition of the "International Quarantine Directory," first issued in 1930 as the "Quarantine Annual," has just been issued by the Office International d'Hygiène Publique, and an English translation can be obtained (price £1 1*s.*) on application to the Ministry of Health. While the directory is of special interest to port sanitary authorities and port medical officers in connexion with their quarantine and other port sanitary duties, it should also appeal to shipping companies, to masters of ships and to ships' surgeons, who will find it particularly useful to have information conveniently to hand on port sanitary dues, costs of fumigation, quarantine anchorages, boarding stations, arrangements for medical treatment and on many other matters concerning the health organisation of the various ports at home and abroad.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 21ST, 1934

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0 (last week 2); scarlet fever, 2517; diphtheria, 1260; enteric fever, 38; acute pneumonia (primary or influenzal), 611; puerperal fever, 46; puerperal *pyrexia, 81; cerebro-spinal fever, 26; acute* polio-myelitis, 13; acute polio-encephalitis, 1; encephalitis lethargica, 6; dysentery, 8; ophthalmia neonatorum, 93. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on July 30th–31st was as follows:—Small-pox,
0; scarlet f[illegible] 49; measles, 736 (last
week 894); [illegible] peral fever, 30 mothers
(plus 8 babie[illegible] 269; poliomyelitis, 2;
"other disea[illegible] t's Hospital there were
20 babies pl[illegible] lmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 1 (1) from enteric fever, 22 (3) from measles, 6 (1) from scarlet fever, 12 (0) from whooping-cough, 38 (3) from diphtheria, 29 (12) from diarrhœa and enteritis under two years, and 14 (3) from influenza. The figures in parentheses are those for London itself.

Of the deaths from measles 2 each were reported from Gateshead, Newcastle-on-Tyne, Birmingham, and Stoke-on-Trent. Whooping-cough proved fatal in 2 cases at Croydon, Kingston-upon-Hull, Leeds and Liverpool. Diphtheria caused 5 deaths at Leeds. Three fatal cases of diarrhœa were reported from Liverpool, no more than 2 from any other great town.

The number of stillbirths notified during the week was 241 (corresponding to a rate of 35 per 1000 total births), including 43 in London.

ROBERT JONES AND AGNES HUNT ORTHOPÆDIC HOSPITAL.—The report for 1933 of this Oswestry hospital states that a beginning had been made with the scheme of reconstructing the temporary buildings, and a programme of work up to 1936 has been decided upon. During the year 1328 patients were treated—787 adults and 541 children. The daily average of 324 in-patients was larger than usual in consequence of extra provision having been made for the treatment of new cases of poliomyelitis. The average stay of each adult was 118 and of each child 105 days. The ordinary account showed a credit balance of £310, mainly due to the larger number of patients, and the increase of voluntary subscriptions.

OBITUARY

MARCUS SEYMOUR PEMBREY, F.R.S., M.D. Oxon.

LATE PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF LONDON

WE regret to announce the death of Prof. Pembrey which occurred unexpectedly at Oxford in a nursing home on Monday, July 23rd. He had recently retired from his professorship, and had arranged to continue much scientific work in his new home near Oxford.

Marcus Seymour Pembrey was the son of an adept in oriental languages connected with the Oxford Clarendon Press. He gained at Christ Church, Oxford, at an unusually early age, an exhibition in science, and graduated in arts in 1889, took the M.B., M.Ch. degrees in 1892, and proceeded to the M.D. in 1895, having secured a Radcliffe Travelling Fellowship. In accordance with the rules of this prize he conducted medical research abroad during the period of its tenure, mainly at Würzburg and Kiel, after which he returned to Oxford as demonstrator of physiology under Burdon-Sanderson and collaborated with Prof. J. S. Haldane in varied scientific research. Valuable work now began to appear from him in the columns of the *Journal of Physiology* and of the *Philosophical Magazine*, among other papers being one in coöperation with Haldane on the determination of the composition of the air, and one, in association with August Gürber, on the influence of bleeding and transfusion on the respiratory exchange. This field of physiological chemistry he continued to cultivate for a long period, writing on the reaction of mammals to changes in temperature, on the influence of bleeding upon the respiratory exchange, and upon the effects of temperature on the output of carbonic acid, and making contributions to literature along similar channels—all worth while, and none more so than his papers in the *Guy's Hospital Reports*.

PROF. PEMBREY

[Photograph by Elliott & Fry

From Oxford Pembrey went as lecturer on physiology to the Charing Cross Hospital Medical School, and had made his mark as teacher when he transferred his services to the school of Guy's Hospital. While lecturer at Guy's he wrote with Dr. C. P. F. Phillips a short manual on the physiological action of drugs. The experiments described were planned to form an introduction to the investigation of the action of medicines upon the living human subject. The modes of applying electric and thermic stimuli to the muscles were set out, and numerous tracings given showing the effects on muscular contraction and on cardiac beats under the administration of saline solutions, and solutions of alcohol, chloroform, strychnine, cocain, digitalin, suprarenal extract, and many other active principles. In 1922 Pembrey was elected F.R.S., and in the same year he collaborated with Prof. Cathcart and the late Prof. Noël Paton in a valuable treatise entitled Practical Physiology." The book was based on a previous one written by Dr. A. P. Beddard, Pembrey himself, and others, and Pembrey contributed the section on advanced experimental physiology. The work rapidly went into further editions, the excellent features of the elementary experimental course being recognised while in Pembrey's section, where the animal work naturally took a more prominent position, the application to man was never lost sight of, and the human subject was profusely used.

We have received the following from two of Prof. Pembrey's colleagues; a fine picture of him is given in their direct words. "As a physiologist Pembrey's interests were distinctly catholic. A devoted lover of nature, he gleaned a wealth of information from the events of everyday life and the texts of his discourses were frequently taken from the farm. He was an ardent "vitalist" and the phrase "all things work together for good" was his guiding principle. He revelled in the struggle for existence and constantly preached the doctrine of self-determination. His early work dealt with respiratory exchange and his measurements of the respiratory quotients of the marmot still form the basis for discussions on the interconversion of fats and carbohydrates. His investigations of the variations in body temperature led to work with the Royal Army Medical Corps upon "heat-stroke" and the equipment of the soldier, and to research into questions of temperature-regulation and sweating. The physiology of reproduction was a constant interest and he published many papers upon the fœtus and newly-born. As a teacher he was not orthodox and his remarks savoured little of the text-book. He always considered that discussion and question and answer were far more satisfactory for educational purposes than systematic lectures. To foster this principle he founded at Guy's the Students' Physiological Society, and for over thirty years it has flourished as a nursery for debate and business procedure. Profoundly impressed by the wide range of variation in the so-called "physiological constants" he continuously waged war upon the term "normal" and to him places of decimals were anathema.

"Pembrey was very happy at Guy's and did everything possible to bring together clinicians and workers in the scientific departments. From his early days at the hospital, when he investigated the physiological aspects in Cheyne-Stokes respiration with the late Sir Frederick Taylor, he was a frequent visitor to the wards, and all the original work in his laboratories was of a practical character. Nowhere can students have received greater encouragement to carry out scientific investigations, and numerous papers in the *Journal of Physiology* and the *Guy's Hospital Reports* testify to the encouragement he gave to team work in research. To his juniors, in these combined exercises, he was a constant source of stimulation, and he was most punctilious as to the even distribution of both responsibility and credit. Almost all of the physicians on the hospital staff were his demonstrators or students, and they would find it difficult to express how much they owe to his friendship and his interest in their work and careers.

"He was indefatigable in his attendance at school meetings. He was almost too fond of arguing, but the school will always be indebted to him for the soundness of his advice and his wise counsel in times of difficulty. A candid and outspoken critic, a loyal friend, his intense humanity made him the repository of the troubles of many of his students and colleagues. He never spared himself in his efforts to assist those whom he deemed worthy, and his cheery optimism helped to dispel gloom from many a difficult situation.

A. F. H.
W. R. S.

WILLIAM FOSTER CROSS, M.R.C.S. Eng.

Dr. W. F. Cross, who died in his sixty-second year on July 14th, at Falmouth, where he was living in retirement, was the son of Mr. W. H. Cross, Clerk to St. Bartholomew's Hospital from 1866 to 1905, and like his elder brother, Dr. E. W. Cross, was born and brought up within its precincts, going to school within a stone's throw—at Merchant Taylors'. Foster Cross qualified in 1896, held resident appointments at Tottenham Hospital and then returned to Bar[illegible] as senior house physician, in that capacity administ[illegible]ing as was then the custom a large number [illegible] anæsthetics. When his term of office expired he to[illegible] up anæsthetics as his career. In 1905 he succeeded Edgar Willett, and in 1916, on Richard Gill's retirement, became chief administrator. Early on he made a contribution on somnoform and was interested in new developments, but as time went on he limited himself more and more to the sequence gas-ether induction with Clover's inhaler followed by chloroform given on a piece of lint; being absolute master of this method he made it look [illegible] was a painstaking teacher, an[illegible] have cause to remember him [illegible] always courteous and good humoured and was never known to be put out even under considerable provocation. On the golf course he was a genial and friendly soul.

CORRESPONDENCE

UNEMPLOYMENT ASSISTANCE: DETERMINATION OF NEEDS

To the Editor of THE LANCET

SIR,—We understand that under the new Unemployment Act a very large number of the unemployed and their families will come to depend partly or entirely for their support upon the allowances granted by the Unemployment Assistance Board.

Our experience, as physiologists and members of the medical profession, leads us to believe that there will be grave danger of widespread physical deterioration, especially among the growing generation, if a considerable section of the population, obliged for reasons beyond its control to depend for maintenance on public funds, is unable to purchase sufficient food and other necessaries for healthy existence.

We therefore welcome the provision made in the Act that the allowance granted to an applicant "shall be determined by reference to his needs, including the needs of any members of the household . . . who are dependent upon him." The definition of "needs" is necessarily left to the Board to determine; it is stated, however, that it is the function of the Board to promote the welfare of the unemployed and "to provide for the re-establishment of such persons with a view to their being in all respects fit for entry or return to regular employment." We suggest that a standard of needs which will fulfil the intention of the Act can only properly be arrived at in consultation with medical and other expert opinion qualified to estimate the minimum requirements of healthy living and the cost of satisfying them for families of various sizes.

"Needs" are conveniently divided into (1) food, (2) rent, (3) fuel, (4) clothing, (5) light, cleansing materials, and sundries. With regard to food, scientific knowledge has now reached the point where it is possible to determine fairly accurately the minimum necessary to maintain health and working capacity. The findings of the recent joint conference representative of the British Medical Association and Ministry of Health committees on nutrition on the constituents of a physiologically desirable dietary and the work of the B.M.A. Committee on specimen minimum diets can no doubt be used as a basis for estimating the minimum expenditure necessary.

With regard to other needs further investigation might have to be undertaken before a satisfactory standardisation could be agreed upon. An adequate expenditure on food will only be secured if some margin is allowed for the small conventional necessities of civilised life.

A scientifically determined scale such as we have in mind would obviously have to be adjusted to changes in the cost of living from place to place and from time to time.

We are, sir, yours faithfully,

RE-EXAMINATION OF MENTAL DEFECTIVES

To the Editor of THE LANCET

SIR,—The judicial *obiter dicta* expressed in a recent case have been adequately commented upon by yourself. Towards the end of the first and second years that a patient has been under the Mental Deficiency Act of 1913 he is visited and, if found *to be still feeble-minded, he will not be officiall*[illegible] *by the Visitors for another five years, when a* [illegible] report has to be made upon his condition and [illegible] whether, if he is discharged, his further supervision and care will be adequate.

Now to make a report prognosticating a patient's state for five years would, indeed, in many cases be an impossible burden to impose upon the Visitors were it not that they are aware that the continuance of a patient under the Act can at any time be determined by others than themselves. But so far as their own powers are concerned, I believe it to be generally *deemed that the arbitrarily ordained period of five years is absurdly long. The cases with which the Visitors are concerned are unhappily for the most part of so feeble-minded a degree that neither at the end of one, two, five or any number of years, is there any likelihood of discharge from the protection of the Act; but the trial upon which you comment is an excellent illustrati*[illegible] *a great difficulty which often confronts th*[illegible]*ors and in which they feel the five-year perio*[illegible]*ous—namely, the case of the young person who* [illegible] *easily pass for normal in the class in which he or she has being, whose defect lies in an incapacity to appreciate current standards of moral conduct, whose volition is feeble and his scholastic* ntellectual capacity below the average. The young male of this character tends to become an "in and ut" delinquent and the young female a more or ess overt prostitute and the mother of babies of arious or unknown paternity. In these cases the Visitors may be in much perplexity as to whether a person of this character should be somewhere Where "Liberty" is interfered with but the means of supervision and care are adequate or in a situation of which prostitution and accidental and unintended motherhood are the likely incidents.

Whatever our views as to the conduct of the defendant in the recent case, it is at least conceivable that like offenders in like circumstances might be as much impressed with the normal appearance and conduct of the girls they have to do with as was the Judge in the case under discussion and the fact that the girl was under the Mental Deficiency Act as little reasonable and proper as it appears to have seemed to him.—I am, Sir, your obedient servant,

Harley-street, W., July 30th. E. D. MACNAMARA.

DISPLACEMENT OF THE INTERNAL EPICONDYLE INTO THE ELBOW-JOINT

To the Editor of THE LANCET

SIR,—I was much interested to read the comments of Mr. Fairbank and Mr. St.J. D. Buxton on my article. I am in complete agreement with them that the title should be reserved for the condition of subluxation with nipping of the epicondyle in the joint, and that cases of outward dislocation of the elbow with epicondylar fracture should be excluded from the category of intra-articular interposition of the epicondyle.

Their insistence on open operation, even in early cases where manipulation is possible, is prompted partly by the fear that the manipulation may damage the ulnar nerve and partly by the necessity for inspecting the damaged nerve, and, if necessary, transposing it. The latter reason is backed up by quoting the general principle that all fractures complicated by nerve injuries should be subjected to open operation. Those surgeons who follow this principle will naturally have no place for a manipulative reduction in their armamentarium. On the other hand, conservative measures in relation to closed fractures complicated by nerve lesions are very widely practised, and it is by no means generally held that such cases should be operated upon immediately. The musculo-spiral nerve, for instance, is not thus treated in closed fractures of the humerus complicated by wrist-drop.

It follows that in the type of case under discussion surgeons who do not see any necessity for immediate exploration of the ulnar nerve will rely on a manipulative reduction in those cases in which it is possible. If the nerve lesion persists an anterior transposition can be performed later and no harm has been done; if it recovers, the need for an operation has been entirely avoided with obvious benefit to the patient. The possibility of inflicting damage upon the ulnar nerve during the manipulation seems a very remote one, but until our practical experience of the method is greater the importance of this factor must necessarily be a matter of individual opinion.

Mr. Fairbank and Mr. Buxton in their letter dealt with many points in connexion with the mechanism of production, and I regret that the desire to be brief prevents me from discussing this aspect of the condition which is of very great interest to me.

I am, Sir, yours faithfully,

Liverpool, July 28th. NORMAN ROBERTS.

CALLING THE ANÆSTHETIST

To the Editor of THE LANCET

SIR,—Recently in the lay press a protest was made against the calling of an anæsthetist to give evidence at an inquest where death had occurred under an anæsthetic while an operation was being performed. The view was put forward that it is very rare for the anæsthetic to be the cause of death. This is also my experience, based on several years' post-mortems conducted on deaths occurring under anæsthetics, and during the present week I have had four such cases consecutively: three from large teaching hospitals, the fourth from a large municipal hospital, where the surgeon and anæsthetist were men of wide skill and experience. The causes of death in these cases were so unusual that I think they are worth recording.

CASE 1.—A man, aged 56, who had previously been cystoscoped, was undergoing an operation for papilloma of the bladder. A question had been raised as to whether this growth was malignant. The patient was prepared with avertin and given gas and oxygen anæsthesia. The papillomatous growth was widely excised by a diathermy knife. After 20 minutes the patient suddenly changed colour and collapsed on the table. The usual restoratives were applied without avail. The post-mortem in this case revealed an old patch of myomalacia cordis with a sclerotic right coronary artery which had been completely occluded. Death was due to coronary thrombosis in which clearly the anæsthesia played no part.

CASE 2.—A woman, aged 62, was being operated on for a carcinoma of the breast which she had had for some months, but had refrained from seeking medical advice. She was prepared in the usual way with avertin and a gas-oxygen-ether anæsthesia was used. The surgeon stated that, after making the usual incisions preparatory to amputating the breast and cutting the pectoralis major, he heard a slight hissing sound. Shortly after the patient collapsed, becoming cyanosed and, finally, respiration ceased. The usual restorative measures, including cardiac massage, were unsuccessful. In this case the post-mortem showed a carcinoma of the left breast, with a large mass of glands in the axilla and in close relation to the axillary vein. The lungs were collapsed; there were a few enlarged glands which looked malignant in the mediastinum. On opening the heart, the whole of the right side was full of froth and blood. The tricuspid valve was raised by a mixture of air and blood. The heart was in diastole. The cause of death in this case was clearly air embolism, and again the anæsthetic had nothing to do with the death.

CASE 3.—A patient, aged 28, a meat porter, was undergoing an operation for a submucous resection of the septum. He was a perfectly healthy man. The nose had been previously packed with 10 per cent. of cocaine and adrenalin. The anæsthetic used was A.C.E. administered through a Hewitt's airway. The posterior nasopharynx was carefully packed by the surgeon with a marine sponge. The operation proceeded normally, and after ten minutes or a quarter of an hour the patient became cyanosed, respiration failed, and he collapsed. Again the usual restorative measures were used without success. The post-mortem in this case revealed a perfectly healthy man. The trachea and lungs, however, were full of blood, which must have come by some means from the naso-pharynx. Death in this case was due to asphyxia from hæmorrhage into the lungs, and again the anæsthetic was not responsible.

CASE 4.—A woman, aged 40, was being operated on for exophthalmic goitre. The right lobe of the thyroid had been removed and half the left lobe. Ether and avertin was the anæsthetic employed. She was returned to the ward in fair condition, and some time afterwards respiratory embarrassment began and she was cyanosed and dyspnœic. The resident, thinking that there was some blood-clot in the wound, took out a few stitches and released a little clot. Her condition, however, did not improve, and later the surgeon returned and did a tracheotomy, having previously passed a catheter into the larynx. The patient died during the second operation, a few hours after the first, under a gas anæsthesia. In this case there was a large hæmorrhage down both scalene muscles and behind the sternum: the lungs were slightly congested. The abdomen showed advanced tuberculous peritonitis. Death in this case was due to hæmorrhage from the thyroid wound and shock, possibly accelerated by the abdominal condition. Clearly the anæsthetic here played no part in the ultimate issue.

I have stated these cases, which happen to be the last four post-mortems I have done this week, of death under anæsthetic to add strength to the contention that the anæsthetist is rarely to blame. It is also true—and we have it on the authority of Sir Thomas Lewis—that the heart is very rarely unable to stand the strain of an anæsthetic. Therefore, I would add my plea to the anæsthetist mentioned in the beginning of this letter, that no useful purpose is served by calling an anæsthetist in these cases except where there has been an obvious accident, such as the wrong joining up of a Junker apparatus. To do so frightens the public and achieves no useful object. Death, in my view, is far more likely to be due to surgical interference, and if evidence is required, then I think the surgeon and not the anæsthetist should be called. In any case, it is the surgeon who is responsible for the operation. I am, Sir, yours faithfully,

Harley-street, W., July 25th. GERALD SLOT.

PERINEO-ABDOMINAL EXCISION OF THE RECTUM

To the Editor of THE LANCET

SIR,—In reply to Mr. Gordon-Taylor it must, I feel sure, be well known that Prof. Grey Turner in 1920 described perineo-abdominal excision as a second stage operation after colostomy. Cases treated by this operation have been shown at the Royal Society of Medicine on many occasions in recent years, and Mr. Gordon-Taylor has given the support of his great experience to it. (Proc. Roy. Soc. Med., 1930.) Within the last two years I have referred with appreciation to this operation in the Index of Prognosis (4th Edition, p. 466), and in my book on rectal surgery where, after describing Prof. Grey Turner's operation, I mentioned (p. 216) two cases in which I had done perineo-abdominal excision in one stage. My recent paper is the outcome of further experience on these lines.

The majority of new operations or manœuvres are developed from already existing methods, and in the present instance I had thought that the title "perineo-abdominal excision *in one stage*" would indicate that the operation to be described was a new or different modification of the existing method. There was no intention on my part to claim originality for the title "perineo-abdominal," and I regret the omission of a reference again to Prof. Grey Turner's original two-stage operation; by doing so the evolution of the one-stage operation would have been shown more clearly, particularly to those who had not seen my previous references.

I am, Sir, yours faithfully,

Harley-street, W., July 30th. W. B. GABRIEL.

THE TREATMENT OF CORNS

To the Editor of THE LANCET

SIR,—During the recent discussion about the recognition of Chiropody at the British Medical Association meeting, it was freely accepted that corns should be cut, also that "long continued treatment" is needed for corns. It is certainly true that, if corns a treated by being cut, they must be treated for a lo time. When, however, it is realised that corns a the result of pressure due as a rule either to faul footwear or to faulty muscle balance, treatment i brief and its results are lasting. Incidentally, restoration of normal muscle balance, the use of suitable shoes, and the *eradication of corns* saves the patient from foot strain and other disabilities.

I am, Sir, yours faithfully,

JAMES K. MCCONNEL.

St. John's Wood, N.W., July 30th.

GLANDULAR FEVER AND INFECTIOUS MONONUCLEOSIS

To the Editor of THE LANCET

SIR,—In his first Lumleian lecture, appearing in your last issue, Dr. H. L. Tidy, referring to the case which I reported to the Royal Society of Medicine in 1915, kindly credits me with something which rightly *belongs to another. It* was Dr. Parkes Weber who, in the discussion that followed my paper, called attention to the similarity of my case to those published by Marchand and Cabot, and referred me to their papers. Dr. Parkes Weber's wide knowledge of medical literature has in the past so often helped me in the investigation of obscure cases that I hasten to take this opportunity of acknowledging my indebtedness to him in this instance. It may be of some general interest to add that the patient whose case was recorded in 1915 is to-day a healthy active man, who has never had a day's illness since his attack of glandular fever in 1911.

I am, Sir, *yours faithfully,*

Sheffield, July 31st. ARTHUR J. HALL.

TRAFFIC IN WOMEN IN THE EAST

A CONFERENCE on this subject was held on July 25th at the London School of Hygiene and Tropical Medicine under the auspices of the joint standing committee of the British Social Hygiene Council and the Conference of British Missionary Societies. Lord Lytton presided at one session and Sir Cecil Clementi, late Governor of the Straits Settlements, at the other. The objects of this preliminary conference were to consider means of making the conference proposed to be held by the League of Nations (probably in Singapore) effective, by increasing interest in the subject among non-official organisations in the East, so that coöperation between governments and non-official organisations in combating the traffic in women might be made easier. Support for these objects was given by the High Commissioner for India, by representatives of the Chinese and Japanese Legations, the Dutch East Indies, and the League of Nations, and by the Bishop of Singapore, prominent members of Protestant and Catholic Missions in the East, and the Salvation Army. The Colonial Office, the Home Office, and the War Office were also represented. Notice was taken of the general movement in the East, as well as in Europe, for the elimination of the tolerated brothel system, and it was stated that medical authorities had very largely ceased to believe in the effectiveness of this system in preventing disease and in assisting in the maintenance of the health of the community. Abolition of regulation and toleration and the setting up of free and efficient venereal diseases treatment centres, available for the whole community, were now believed to be the line of progress on the medical and health side, so that there was no longer any serious conflict between the moral and medical outlook.

A number of resolutions were carried strongly supporting further action by the League of Nations and by the various Eastern Governments, with a view to securing inter-governmental action, which at present, it was stated, is the main hindrance to the elimination of the traffic in women and children.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Summer Adjournment

Both Houses of Parliament adjourned on Tuesday, ly 31st, for the Summer recess. They will reas-mble on Oct. 30th, but in accordance with recent rocedure power was given to the Lord Chancellor nd the Speaker of the House of Commons to summon heir respective Houses earlier if necessity should rise.

Safety and Health in Mines

On July 17th, in Committee of Supply, Mr. E. BROWN, Secretary for Mines, said that there were now open and completed at the moment 145 pithead baths provided out of the Welfare Fund, and 25 were under construction, making a total of 170. Previous to the establishment of the Fund there were 32 other baths, so that at the moment they had 202 pithead baths either constructed or under construction, and the number of employees provided with baths was 248,332, or nearly one-third of the men on the books of the collieries. He had heard the great reform undertaken in the new regulations regarding lighting described by a prominent mining engineer as in his judgment the greatest reform for a generation.

The new Order fell into three parts. Part I., which comes into operation on Sept. 1st next, dealt with lighting by means of safety lamps; Part II. dealt with lighting by means otherwise than by safety lamps; and Part III. dealt with lighting above ground and with the very important subject of whitewashing underground. Part II. came into operation on July 1st this year, and Part III. comes into operation on Sept. 1st this year. Part I. was designed to raise the standard of lighting by means of safety lamps, and it was estimated that inside the two and a quarter years allowed for the change-over the lamps provided under the new standard would give twice as much light as the lamps now used, and 300,000 lamps would have to be replaced. As regarded Part II., in safety lamp mines the use of fixed lights provided by current from the electric mains had hitherto been restricted to areas not within 300 yards of the face. Part II. extended this lighting under special precautions to roads ventilated by intake air up to 50 yards from the working face, and in other roads up to 100 yards from the working face. Part III. provided for sufficient lighting on the surface where persons regularly worked, and underground at shaft insets and shaft sidings; while the whitewashing would take place compulsorily at important places underground such as sidings, landings, pass-bys, offtakes, and rooms containing engines, motors, and other appliances.

DEEP MINES

Mr. TINKER called attention to the extreme depth—over 4000 feet in some cases—at which miners were called upon to work and the high temperatures which they had to endure. He said he hoped that this matter would be dealt with as mines were getting deeper and deeper.

Lord BALNIEL said that infinite trouble and care had been taken in order to deal with this problem. He did not think that anything more could be done considerably to reduce the temperature. Modern science did not know the way.

Mr. DUNCAN GRAHAM urged a rigid fixed working day for miners, a maximum beyond which he should not be asked to go, and a shorter working day for the men in deep mines.

Mr. BROWN, in reply, quoted Dr. J. S. Haldane, who pointed out in a note dated November, 1933, that the Royal Commission on Health and Safety in Mines (1900) unanimously drew the conclusion that "on the whole we do not think that any good object would be served by prescribing a limit of wet bulb temperature for the carrying on of work in mines." Neither the Royal Commission of 1909, Dr. Haldane went on, nor any report of the Deep and Hot Mines Committee, has suggested any definite limitation of the depth at which coal could be worked beyond pointing out that the greater the depth the better the ventilation must be. The idea that 4000 feet would prove to be about the maximum depth at which men could work dated from a time when knowledge of the subject was still very limited.

Unemployment and Health Insurance

Mr. CLARRY said that in response to a request by certain of his constituents he begged to present a petition signed by 16,390 persons, mainly resident at Newport (Mon.), protesting against the provisions of the new Unemployment Act and the National Health Insurance (Amendment) Act, 1932. The petitioners alleged that the provisions of these Acts embodied a savage attack on the unemployed and their families, and further that they would inflict severe privations on thousands of men, women, and children, and cause disruption of family life and the pauperisation of the unemployed through circumstances over which they had no control.

Progress of Town Planning

In the House of Commons on July 26th, on a vote for the Ministry of Health, Sir P. HARRIS said that housing and town planning ought to be regarded as one problem. In Liverpool they had a complete town planning scheme, and in the County of London already there were 18 town planning schemes covering an area of something like 37½ square miles. That was all to the good. He understood that the London County Council were going to make a complete survey and a complete scheme of town planning inside their boundary. But he believed that the Minister of Health would agree that all boundaries made for town planning were more or less artificial. There was now no real division between the town and the country. In London, what made the problem so difficult was that of the increase of 920,000 persons according to the last census fewer than 500,000 was due to natural increase, or the ordinary growth of the population. The balance was made up by the migration of over 400,000 people. They were flowing into this big area unorganised, unplanned largely, and there was no authority that was big enough to apply its mind to the position except the Government, particularly the Ministry of Health, and he might add the Ministry of Transport and the Ministry of Labour. More than half of this increase of population was outside the county; inside the county the population was going down. In the greater London area there were 135 local authorities. This led to a division of responsibility in the matter of town planning which made the problem almost insoluble. The first thing to be done was to have a green girdle round London to stop the further urban development of London unless there was a reasonable provision for parks, gardens, and open spaces. He urged the Minister of Health to give a lead to the local authorities, to get them together and encourage and stimulate their coöperation so that they might have town planning, not next year or the year after, but in 1934.

Sir FRANCIS FREMANTLE said that houses were growing up generally in a way that was a disgrace to the present age. Town planning required to come first and the housing afterwards. Planning was slacking unnecessarily owing to difficulty in visualising the future. He asked the Minister to tell local authorities that it was in their power now to plan provisionally for areas now purely rural, leaving the way open for a supplementary scheme later. It was essential to plan for the immense movement of population. About 100,000 persons were being moved out of London every year and settling down in the areas round. As far as possible they wanted to associate that movement with the resiting of factories. From a national point of view they did not want to encourage factories to move down from the North. The movement of factories must be allowed largely to decide itself, and the placing of houses ought to follow the placing of factories.

Sir HILTON YOUNG, Minister of Health, said that housing work and planning work had been brought together into a single department. His policy had always been directed towards the promotion of regional planning committees wherever they were required. Wisdom and progress were to be obtained by promoting reasonable coöperation between those authorities and not by arbitrarily overriding them. In ten years they had increased the number of executive committees from one to 75. He thought they had probably the most practical and efficient arrangement that they could get for the planning of London as long as London government was on the present lines. But he agreed that a problem for the future was the rationalisation of London government as a whole, in order, among other things, that the planning of London might be dealt with on a more reasonable basis.

Road Traffic Bill

In the House of Commons on July 26th a motion to agree with the Lords' amendments, deleting the provision in Clause 1 that the speed limit of 30 miles an hour should not apply in built-up areas between midnight and 5 A.M., was carried by 158 votes to 24. The House also agreed with the new clause inserted by the Lords making it illegal to sell a motor vehicle which was not fitted with an efficient silencer.

HOUSE OF COMMONS

THURSDAY, JULY 26TH

Encephalitis following Vaccination

Mr. GROVES asked the Minister of Health whether his attention had been called to the death of Leonard George Jennings, aged 18 years, who died from encephalitis resulting from vaccination, performed as a condition of employment with the Gas Light and Coke Company; whether he was investigating this case; and whether he would call the attention of employers of labour to the possible dangers of vaccination.—Sir HILTON YOUNG replied: The answer to the first two parts of the question is in the affirmative. As regards the last part, the opinion has already been expressed in circulars issued by my Department that it is not generally expedient to press for the vaccination of children of school age or of adolescents who have not previously been vaccinated, unless they have been in personal contact with a case of small-pox or directly exposed to small-pox infection.

Maternal Mortality Circular

Captain ELLISTON asked the Minister of Health when he proposed to issue to local authorities the promised further circular on maternal mortality.—Sir HILTON YOUNG replied: I hope to issue this circular in the early autumn.

MONDAY, JULY 30TH

Eggs Supplied to Pensions Hospitals

Captain HEILGERS asked the Minister of Pensions the country of origin of eggs supplied to patients in the Queen Mary's Hospital, Roehampton.—Captain HUDSON, Lord of the Treasury, replied: The country of origin of the eggs used at this and other Ministry hospitals varies according to the season and current contract prices. A preference of 25 per cent. ad valorem is given to English eggs over foreign.

Diphtheria at a Grammar School

Mr. HALES asked the Minister of Health if his attention had been called to a serious outbreak of diphtheria at the Chipping Campden grammar school and that the outbreak was stated to have been spread by those students attending the school who used a private swimming pool at Broad Campden, the water of which was not changed more than once a year; and if he would take steps to have all su pools brought under the supervision of his inspectors. Mr. SHAKESPEARE replied: Only one case of diphth was notified in the Campden Rural District during the l four months. In his annual report the Medical Officer o Health reported that 21 cases occurred in 1933, most o them at this school. My right hon. friend has no information that the outbreak was attributed to infection from bathing, and he is not aware that the causal organism of diphtheria has ever been found in water. As regards the second part of the question, the Public Health Act, 1875 gives the local authority or any of their officers a right of entry to any premises for the purpose of ascertaining whether any nuisance exists, and my right hon friend does not think that it would be good policy for detailed inspection of swimming pools to be carried out by officers of the central authority.

Inspection of Private Swimming Pools

Mr. HALES asked the Minister of Health what control was exercised by his department over private swimming pools for which a charge for admission was made; if regular inspections were made by qualified inspectors of the water; and, if not, would he in the public interest take the necessary steps to see that they were brought under his jurisdiction.—Mr. SHAKESPEARE replied: My right hon. friend has no statutory powers to exercise direct control over these pools. As stated in my answer to a previous question the Public Health Act, 1875, gives a right of entry to the local authority or any of their officers for the purpose of ascertaining whether any nuisance exists and my right hon friend proposes to call attention to these powers in his next annual report, which will shortly be issued.

Exhaust Fumes of Motor Vehicles

Mr. ALBERY asked the Minister of Transport whether any steps had recently been taken to ascertain what harmful effects are being suffered in crowded thoroughfares as a result of the exhaust fumes of motor vehicles.—Mr. HORE-BELISHA replied: This matter came under the consideration of a Home Office Departmental Committee a year ago. Their report did not suggest that there was any such evidence of injury being caused by exhaust fumes to the health of drivers and conductors or of persons using the highway as would justify legislative action. I may, however, add that the examiners appointed under the Road Traffic Act, 1930, and the Road and Rail Traffic Act, 1933, are required to look for defects in exhaust pipes in the public service vehicles and goods vehicles which they examine.

Use of Motor Horns at Night

Mr. WILLIAM SHAW asked the Minister of Transport whether it was his intention to schedule areas in which during certain night hours the use of motor-horns would be forbidden; and whether this experiment was to be confined to the metropolitan area.—Mr. HORE-BELISHA replied: I intend to try this experiment and not to limit it to the metropolitan area.

Hospital Treatment of Pensioners

Sir WILFRID SUGDEN asked the Minister of Pensions the future policy of his department in regard to hospital treatment of pensioners; whether it was proposed to continue the existence of Ministry of Pensions institutions or whether pensioners would receive in-patient treatment in voluntary and/or rate-aided hospitals at the Ministry's expense; when such change, if any, would be effected; and if he would state the number of pensioners admitted to Ministry institutions for treatment for the years 1931, 1932, and 1933, and the number admitted to other institutions for treatment, approved by the Ministry, for the same years.—Major G. C. TRYON replied: The policy of the Ministry is to make use of civil hospitals as far as possible consistently with the interests of the Ministry's patients, but there are certain types of war disability as, for example, nervous and mental disorder, epilepsy, paraplegia, and certain types of surgical case, for which either ordinary civil institutions do not provide which can be more suitably dealt with in specialised nistry institutions. No change is contemplated in s policy, which will continue to be pursued so long as the erests of the patients demand. The particulars asked for the remainder of the question are as follows:—

Number of cases (not including pensioners certified as unsound mind in Public Mental Hospitals) admitted hospital as in-patients—

	1931	1932	1933
military hospitals, including Queen Mary's Hospital, Roehampton	7,501	6,264	5,790
a voluntary hospitals and general civil hospitals ..	3,478	2,541	1,966
Total	10,979	8,805	7,756

TUESDAY, JULY 31ST

Medical Inspection of Mental Defectives

Dr. O'DONOVAN, asked the Minister of Health if his attention had been drawn to remarks by the Recorder of the City of London concerning a woman detained at Epsom under sub-section (1) of Section 11 of the Mental Deficiency Act, 1931; and if he would institute inquiries whether any special amendment of the Act with regard to the frequency of medical inspections was called for in the light of experience of the working of the Act.—Sir HILTON YOUNG replied: Yes, sir. These remarks appear to have been based upon inadequate information. Apart from the periodical statutory reviews to which the Recorder referred, mental defectives in institutions are under the constant observation of the medical staff. Suitable cases are frequently given leave of absence to test their fitness for discharge, and the Board of Control can discharge any patient at any time. The second part of the question does not, therefore, appear to arise.

Certified Dairy Herds in Scotland

Commander COCHRANE asked the Secretary of State for Scotland whether he was aware that, in the case of a certified herd, the Department of Health for Scotland stated that the proprietor had no right of appeal against the decision of a county veterinary surgeon and had declined to appoint an impartial arbiter at the expense of the proprietor; and whether, in view of the importance of the matter to all proprietors of certified herds, he proposed to take any action.—Sir GODFREY COLLINS replied: Under the Milk (Special Designations) Order (Scotland), 1930, which regulates these matters, there is a right of appeal to the Department of Health by the licencee of a certified herd against the decision of a licensing authority to refuse or revoke a licence. There is no provision for an appeal on any other ground, and I understand that although the Order, or one in similar terms, has been in operation for many years, no request has been made for an extension of the right of appeal. The Order is at present under revision in view of the provisions of the Milk Act, 1934, and the question whether the Order should be amended in this direction will be considered.

Turkish Compensation for Death of British Officer

Mr. EDEN, Lord Privy Seal, stated that the Turkish Government had of their own initiative expressed a desire to make a voluntary payment to the relatives of the late Surgeon-Lieutenant Robinson, who was shot dead by a Turkish sentry off the coast near Samos. The compensation, he said, amounted to £2000, and he understood that this sum had already been paid.

MEDICAL NEWS

Royal College of Physicians of London

At a meeting on July 26th, with Lord Dawson of Penn, the president, in the chair, the following fellows of the college were elected officers for the ensuing year:—

Censors: Prof. W. Langdon Brown, Dr. Charles Bolton, F.R.S., Dr. Gordon M. Holmes, F.R.S., and Dr. Letheby Tidy. Treasurer: Dr. S. P. Phillips. Registrar: Sir Raymond Crawfurd. Harveian Librarian: Dr. Arnold Chaplin. Assistant Registrar: Dr. C. E. Newman. Library Committee: Dr. H. R. Spencer, Dr. J. J. Conybeare, Dr. A. E. Clark-Kennedy, and Dr. J. D. Rolleston. Curators of the Museum: Dr. G. E. Beaumont, Dr. Maurice Davidson, Dr. H. Gardiner-Hill, and Dr. R. A. Hickling. Finance Committee: Dr. T. Watts Eden, Dr. C. R. Box, and Sir Charlton Briscoe.

The following were elected examiners:—Chemistry: Mr. Herbert Lambourne and Mr. C. S. Gibson. Physics: Mr. W. H. White and Prof. F. L. Hopwood. Materia Medica and Pharmacology: Dr. Philip Hamill, Dr. K. D. Wilkinson, Dr. E. Gordon Holmes, Dr. Clifford Hoyle, and Dr. R. St. A. Heathcote. Physiology: Prof. C. A. Lovatt Evans, F.R.S., and Prof. D. T. Harris. Anatomy: Dr. Thomas Yeates. Pathology: Dr. C. M. Wilson, Dr. C. F. T. East, Prof. Geoffrey Hadfield, and Dr. P. N. Panton. Medical Anatomy and Principles and Practice of Medicine: Dr. David Forsyth, Dr. C. M. Hinds Howell, Dr. Theodore Thompson, Dr. A. G. Gibson, Sir Maurice Cassidy, Dr. Reginald Miller, Dr. H. C. Cameron, Dr. A. E. Naish, Sir Stanley Woodwark, Dr. Anthony Feiling, Prof. W. H. Wynn, and Dr. J. W. McNee. Midwifery and Diseases peculiar to Women: Mr. J. M. Wyatt, Mr. A. J. McNair, Mr. Leslie Williams, Prof. Daniel Dougal, and Prof. R. P. Ranken Lyle. Public Health: (Part I.) Prof. M. E. Delafield, and (Part II.) Dr. C. T. Maitland. Tropical Medicine: Prof. R. T. Leiper, F.R.S., and Dr. N. Hamilton Fairley. Ophthalmic Medicine and Surgery: Dr. W. J. Adie. Psychological Medicine: (Part I.) Dr. R. D. Gillespie and (Part II.) Dr. S. A. Kinnier Wilson and Dr. A. A. W. Petrie. Gynæcology and Obstetrics: Mr. J. P. Hedley. Laryngology and Otlogy: Mr. Lionel Colledge. Radiology: Mr. James Hancock Brinkworth, D.Sc., and Dr. H. K. Graham Hodgson.

The following appointments were announced: Sir Henry Dale, F.R.S., as Harveian orator, 1935 (the forthcoming Harveian Oration in October next will be delivered by Dr. James Collier); Dr. D. T. Davies as Bradshaw lecturer, 1935; Dr. J. S. Bolton, F.R.S., as Lumleian lecturer, 1935; Dr. A. A. Moncrieff as Goulstonian lecturer, 1935; Dr. J. D. Rolleston as FitzPatrick lecturer, 1935; Prof. C. R. Harington, F.R.S., as Oliver-Sharpey lecturer, 1935; Prof. C. G. Seligman, F.R.S., as Lloyd Roberts lecturer, 1935; and Sir Bernard Spilsbury as Croonian lecturer, 1936.

The Murchison scholarship was awarded to Stanley George Browne, M.R.C.P., of King's College Hospital medical school. Sir Humphry Rolleston was re-elected a representative of the college on the executive committee of the Imperial Cancer Research Fund, and Dr. Letheby Tidy the representative on the General Medical Council.

The college expressed its full sympathy with the efforts of the Anti-Noise League to secure an abatement of avoidable noise.

The President briefly reported on the valuable work done at the request of the college by Dr. D. T. Davies, Dr. L. E. H. Whitby, and Dr. H. K. Graham Hodgson in a joint research into pneumococcal penumonia. The college undertook to sponsor the publication of this report.

The President reported the progress of the tuberculosis survey scheme, which had been approved by the comitia in principle on a previous occasion. He explained that it was intended to investigate pre-clinical tuberculosis, by means of clinical investigation radiological examination, and Mantoux-testing. A series of expert committees had sat and reported on standard techniques for the radiological and tuberculin investigations, so as to ensure uniformity throughout the working of the scheme. There had been great difficulties in arranging for the widespread coöperation between many different bodies and persons, by which means alone so large an enterprise could succeed, but all these problems appeared to have been solved. It is, however, proposed to institute the survey only on a limited scale, in the boroughs of Camberwell, Bermondsey, and Westminster, during the first year, in case of difficulties arising, but it was the unanimous opinion of the experts who have been consulted that even if the scheme as a *whole cannot be carried through very valuable information* will be obtained.

A report of the committee of management was considered and the following recommendation of the committee was approved :—

> "That the present regulations regarding the admission of graduates in medicine and surgery of recognised foreign universities be revised as from Oct. 1st, 1934, to provide that such graduates be admissible direct to the examination in anatomy and physiology, and, after passing in these subjects, be required to follow for 36 months the practice in medicine, surgery, and midwifery of a recognised medical school and hospital in Great Britain or Ireland before they are admissible to the final examination."

The following candidates satisfied the censors' board and were admitted members of the college :—

Clifford Edward Allen, M.D. Lond. ; Charles Barry Bamford, M.D. Liverp. ; Hugh Astley Cooper, M.B. Lond. ; James Fenton, M.D. Birm. ; David Glass, M.B. Belf. ; Idris Griffiths Jones, M.B. Lond. ; Kenneth David Keele, M.B. Lond. ; Alexander Kennedy, M.B. Lond. ; George Raymond Kirk, M.B. N.Z. ; Don John Telesphor Leanagé, M.D. Lond. ; Terence Joseph Lee, M.B. Melb. ; Leslie George Norman, M.B. Lond. ; Wilfred Harding Owles, M.B. Oxf. ; Albert Ray Southwood, M.D. [illegible] herland Strachan, M.D. Glasg. ; Edı [illegible] M.D. Lond. ; and Hovsep Aghék Y [illegible]

Licences to practise were conferred upon 159 candidates (141 men and 18 women) who have passed the final examination of the Conjoint Board and have complied with the college by-laws. The following are the names and medical schools of the successful candidates, viz. :—

Winifred L. L. Acraman, Cardiff ; M. Altmann, Frankfurt and London ; Alberta I. Andrews, Royal Free ; Margaret D. Baber, Univ. Coll. ; K. C. Bailey, Camb. and St. Thos. ; Mary Barber, Royal Free ; T. L. Barbour, Camb. and Guy's ; C. Bard, London ; F. R. Berridge, Camb. and St. Geo. ; R. H. Blazeby, Guy's ; C. H. Bliss, St. Thos. ; J. R. Bodington, Camb. and London ; A. G. W. Branch, Bristol ; N. P. Brown, Camb. and Middx. ; E. J. Bury, Camb. and St. Mary's ; I. Byer, St. Bart.'s ; W. A. Carey, Camb. and King's Coll. ; R. M. Case, Birmingham ; Jean M. Cass, Royal Free ; A. M. Chapnick, Westminster ; S. C. Chatterjee, Calcutta and West London ; R. F. Clarke, St. Bart's S. G. Clayton, King's Coll. ; H. M. Clegg, Leeds; Gladys E. Clyne, Royal Free ; S. G. Collingwood, St. Bart.'s ; A. B. Concanon, Liverpool ; D. D. Cranna, Manchester ; F. H. Culshaw, Camb. and St. Bart.'s ; R. S. Dale, St. Mary's ; D. H. Davies, Camb. and Middx. ; D. L. L. Davies, St. Bart.'s ; G. M. Denning, Camb. and St. Mary's ; F. H. D'Souza, Guy's ; N. J. Dias, St. Bart.'s ; Bessie Dodd, Liverp. ; Dorothy S. R. Drew, Royal Free; R. C. Easterling, King's Coll. ; T. S. Eddy, Cape and Guy's ; K. C. Eden, Univ. Coll. ; J. D. Fergusson, Camb. and St. Thos. ; I. C. Fletcher, Camb. and Middx. ; A. F. Fowler, St. Thos. ; P. S. Fox, Leeds ; C. S. France, Manchester ; I. N. Fulton, Camb. and St. Bart.'s ; E. Galinsky, Univ. Coll. ; R. H. Gardiner, Oxon and King's Coll. ; J. C. Garland, Middx. ; D. J. Gilbert, King's Coll. ; A. J. [illegible] St. George's ; C. H. Goodliffe, Birmingham ; M. E. [illegible] O'D. C. Grattan, Camb. and St. Thos. [illegible] ; P. R. Greeves, Oxon and Middx. ; A. V. [illegible] V. P. Gupta, Lucknow and West London ; A. H. Hall, Univ. Coll. ; H. A. Hamilton, Camb. and Guy's ; M. Hamilton, Univ. Coll ; E. A. Hardy, Westminster ; E. E. Harris, Camb. and St. Bart.'s ; O. L. Hewson, Birmingham ; J. H. Hovell, Charing Cross ; T. H. Howell, Camb. and St. Bart.'s ; J. H. Hudson, Leeds ; H. C. Hugh, St. Bart.'s ; J. Hughes, Camb. and St. Bart.'s ; C. C. Hurst, Manchester ; J. R. Hutcheon, London ; I. H. Jenkins, St. Thos. ; J. R. R. Jenkins, St. Bart.'s ; B. S. Jirge, Bombay and London ; D. M. Jones, Cardiff and St. Bart.'s ; E. J. Jones, Cardiff and Middx. ; E. I. Jones, King's Coll. ; J. E. V. Jones, Camb. and St. Thos. ; R. N. Jones Birmingham ; W. M. P. Jones, Cardiff ; Nora L. Keevil, Royal Free ; J. H. Kellgren, Univ. Coll. ; M. B. Khan, Leeds ; D. M. King, Cape Town ; N. F. Kirkman, Manchester ; R. M. Kirkwood, St. Bart.'s ; Freda H. Knight, Manchester ; R. W. G. [illegible] Oxon and Manchester ; J. L. Lanceley, Liverpool [illegible] Camb. and St. Thos. ; J. V. Laverick, [illegible] Lewis, Manchester ; F. D. M. Livingstone, Camb. and St. Bart.'s ; M. C. W. Long, St. Mary's ; A. J. McCall, Liverpool ; D. C. MacCarthy, St. Bart.'s ; D. P. McCoy, Camb. and St. Bart.'s ; G. G. Macdonald, Univ. Coll. ; E. H. Markby, London ; T. D. M. Martin St. Thos. ; A. G. C. Mason, Middx. ; E. B. Z. Masterman, Camb. and St. Bart.'s ; S. G. Mayer, Camb. and London ; A. Moore, Univ. Coll. ; G. H. Moore, Manchester ; P. Morr [illegible] Moynahan, Univ. Coll. ; P. H. Newma [illegible] Guy's ; Ivy E. Oliver, Royal Free ; M [illegible] G. R. C. Palmer, St. Thos. ; R. S. [illegible] R. Peters, Univ. Coll. ; R. A. Piachaud, [illegible] T. H. Pierce, Liverpool ; E. H. Platts, Camb. and Leeds ; R. H. Purnell, St. Bart.'s ; L. Rabinovitch, Leeds ; F. Riggall, Western Univ. (Ontario) ; W. G. S. Roberts, Birmingham ; A. T. Roden, St. Bart.'s ; Katharine C. Rogers, Royal Free ; M. Rooms, Leeds ; W. T. Ross, Cape and St. Bart.'s ; C. R. St. Johnston, Birmingham ; Irene E. Sandford, Royal Free ; D. Sanyal, Lucknow and London ; R. S. F. Schilling, St. Thos. ; E. A. Schott, Heidelberg and Guy's ; S. K. Sen, Patna ; H. H. S. Sherwill, Edinburgh ; H. G. Silvester, Univ. Coll. ; N. Sivolella, St. Bart.'s ; K. Soddy, Univ. Coll.; A. W. Stal Camb. and St. Bart.'s ; J. Starkie, Manchester ; J. R. St. Stead, London ; F. G. St. C. Strange, London ; J. S. F. Sut Guy's ; J. C. Thomas and M. J. H. Thomas, U Coll. ; Mary G. Thomas, Bristol ; L. N. Trethowan, Guy R. H. A. Turner, Camb. and Westminster ; T. H. Tulp Bombay and West London ; R. W. D. Turner, Camb. and Thos. ; J. K. B. Waddington, Liverpool ; R. C. Walch, Manchester and St. Bart.'s ; Kathleen M. Webster, Royal Free ; B. Weiner, St. Bart.'s ; O. C. Wilkinson, Birmingham ; M. W. Williams, Univ. Coll. ; F. L. Wollaston, Bristol ; B. L. E. Wong, Guy's ; G. M. Woolford, St. Thos. ; Fanny D. Wri Royal Free ; K. H. Wright, Guy's ; and Betty M. Zeal, Univ Coll.

Diplomas were conferred (jointly with the Royal College of Surgeons) upon candidates whose names were given in our issue of July 21st (p. 172).

The college will be closed for cleaning on Saturday, August 4th, and will reopen on Monday, Sept. 17th.

University of London

At recent examinations the following candidates were successful :—

M.D.

Branch I. (Medicine).—H. G. Anderson, St. Bartholomew's Hosp. ; W. E. K. Coles, Univ. College Hosp. ; T. A. L. Davies, St. Thomas's Hosp. ; S. N. Evans, Guy's Hosp. ; Anderson Garland, King's College Hosp. ; J. C. Heather, Guy's Hosp. ; L. H. Howells, London Hosp. ; K. D. Keele, St. Bartholomew's Hosp. ; Alexander Kennedy, St. Thomas's Hosp. ; F. P. L. Lander, Middlesex Hosp. ; L. G. Norman (University Medal), Univ. College Hosp. ; † Edward Renbom, St. Bartholomew's Hosp. ; T. S. Stone and F. W. Ta'Bois, London Hosp. ; M. R. Thomas, Univ. College Hosp. ; F. W. Willway, M.S., King's Coll. Hosp. ; and A. L. Wingfield, St. Thomas's Hosp.

† Awarded a Mark of Distinction.

Branch II. (Pathology).—Dorothy Woodman, Lond. (R.F.H.) School of Med. for Women.

Branch IV. (Midwifery and Diseases of Women).—Marian J. Cunning, Lond (R.F.H.) School of Med. for Women ; and K. M. Masani, Middlesex Hosp.

Branch V. (Hygiene).—R. C. Cohen, Univ. College Hosp. and Lond. School of Hyg. & Trop. Med. ; D. D. Payne, St. Thomas's Hosp. and Lond. School of Hyg. & Trop. Med. ; and G. E. B. Payne, Univ. College Hosp. and Lond. School of Hyg. & Trop. Med.

B. St. J. Steadman has satisfied the examiners in the third (B.D.S.) examination in dental surgery and R. F. Pusey has passed in Group I. of the examination.

Royal College of Physicians of Edinburgh

The council will shortly award two Kirk Duncanson fellowships for medical research. Particulars will be found in our advertisement columns.

Royal College of Surgeons of Edinburgh

At a meeting of the college on July 25th, with Dr. A. H. H. Sinclair, the president, in the chair, the following, who passed the requisite examinations, were admitted Fellows :—

George Herbert Cashmore, M.B. Adel. ; John Rupert Crumbie, M.R.C.S. Eng. ; Philip Norman Cutner, M.B. Edin. ; Henry Leslie Nugent Davies, M.B. Birm., Alexander Duff, M.B. Glasg. ; Ronald Walter Graham-Campbell, M.R.C.S. ; Bruce Rudolph Hallows, M.D. Melb. ; Rowland Anthony Harold Krynauw, M.B. Edin. [illegible] Kellar, M.B. Sydney ; Nathan Pencharz, [illegible] Wilfred Pottinger, M.B. Sydney ; Suresl [illegible] M.B. Calcutta ; Cyril Francis Sullivan, M.D. Ontario ; Abraham Track, M.D. Toronto ; Desmond Coleman Trainor, M.B. Sydney ; Albertus van der Poel, M.B. Edin. ; Andrew Watt, M.B. Edin. ; Robert James Wilson Withers, M.B. Belf. ; and Arthur Greville Young, L.R.C.P. Edin.

The following candidates were granted the diploma of L.D.S.

S. H. Harrison, Eleanor L. Mackinnon, I. J. G. Mowat, G. H. Fletcher, E. I. Kohn, E. M. Hope, Ernst Levy, Siegfried Bendix, N. G. Henry, and W. M. Hendry.

Scottish Conjoint Board

At recent examinations by the Board of the Royal Colleges of Physicians and Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow, the following candidates were successful :—

L.R.C.P., L.R.C.S., AND L.R.F.P.&S.

[illegible] rtz, Eleonore Bergmann, John [illegible] Koebner, Ernst Lucas, S. K. [illegible] C. H. Rothschild, C. Becker, [illegible] Walter Auerbach, Werner [illegible] Kurt Samson, [illegible] Alfons [illegible] ltmann, [illegible] Perkins, Erich Gostynski, M. S. Khan, [illegible] Hans A. S. W. Buchanan, R. H. [illegible] J. R. Jungmann, Richard Hamburger, Mathilde [illegible] Bruce, H. A. Thorner, J. F. Macgregor, L. C. Goldwater, Harry Fleming, P. T. Hauff, F. A. Paul, and L. H. Becker.

ADDRESSES AND ORIGINAL ARTICLES

THE TOXÆMIAS OF PREGNANCY*

By DAME LOUISE McILROY, D.B.E., M.D.,
D.Sc. Glasg., D.Sc. Lond., F.C.O.G., M.R.C.P.
DIRECTOR OF THE OBSTETRICAL AND GYNÆCOLOGICAL UNIT,
ROYAL FREE HOSPITAL, LONDON; PROFESSOR OF
OBSTETRICS AND GYNÆCOLOGY IN THE
UNIVERSITY OF LONDON

I.—CLINICAL AND BIOCHEMICAL INVESTIGATION

WHAT do we understand by the term "toxæmia of pregnancy"? It is difficult to define it, for no specific toxin has been found in connexion with this group of clinical symptoms. We know very little about toxæmia. We know that some alteration takes place in normal pregnancy and that there is an exaggeration of this alteration which is due directly to gestation or to some previous functional derangement in the maternal organism. It is also impossible to make any exact classification of the toxæmias of pregnancy, for their manifestations are varied. The cut-and-dried classification of the text-books is out of date and for teaching purposes we can only describe various symptoms or groups of symptoms. Different symptoms may preponderate at various stages of pregnancy but the ultimate cause is the same in most cases.

If we had a fuller knowledge of the metabolic changes which normally take place in pregnancy we might better appreciate the danger signals. At present we muddle along and occasionally someone throws a beam of light to guide us on our way. Physiologists as a whole, with the exception of Noel Paton, Cathcart, Pembrey, Barcroft, Mellanby, and Mrs. Mellanby, have taken little interest in the study of human metabolic function in pregnancy. What knowledge we have of toxæmia we have had to acquire ourselves with the help of the biochemists in hospital laboratories. To-day, however, as a result of the establishment of antenatal treatment, there is a wealth of material for investigation at hand in our hospitals and clinics. The earlier causes can be recognised the earlier will symptoms be treated and serious complications prevented.

The subject of toxæmia should be freed from old theories. It should be approached from a much wider standpoint. It has been proved of late that the toxic condition is due mainly to deficiencies in nutrition, and in most cases it is associated with some breaking down of the normal functional activities of various digestive and excretory organs.

The significance of the gravity of the patient's condition must necessarily be determined from clinical observation until further definite laboratory tests are obtainable. Our diagnosis is in most cases limited to the investigation of the reaction of the patient to the disease and to the treatment we have carried out successfully or otherwise. Laboratory work has helped in research but the multitude of tests which are devised from time to time are of little practical value unless they can be adapted for clinical use.

Influence of Toxæmia upon Maternal Mortality and Maternal Morbidity

Puerperal sepsis is given first place in all statistical returns of maternal death-rates. In most of these we find that toxæmia comes next in the list. In the Registrar-General's returns for the years 1921–30 this factor is given a high place. But deaths from hæmorrhage, accidents of pregnancy, and abortion owe their origin in a large measure to the malnutrition of the patients as the result of diet deficiencies. In the Royal Free Hospital the maternal death-rate for the years 1921–30 was 2·8 per 1000. If the deaths from toxæmia, obstetric shock, and hæmorrhage were added together they would stand much higher in the causation of death than puerperal sepsis. We know from experience that one of the most important predisposing cases of sepsis is toxæmia or malnutrition and that, therefore, the toll of maternal death-rate from sepsis could be reduced by the improved prophylaxis of toxæmia. The recent investigations of workers on toxæmia have opened up a new era in the prevention and treatment of complications of pregnancy due to malnutrition and diet deficiency. This research will expand and will give promising results as soon as the obstetricians realise that it is on these lines that their attention is to be focused. The maternal mortality-rate will be reduced in time by careful attention to diet deficiency and the consequent malnutrition, just as infant mortality and morbidity have been reduced by expert supervision of nutrition through infant welfare clinics or attention in private practice.

Bingham[1] states that in U.S.A. over 4000 women die annually from toxæmia and that this is to a great extent a preventable disease. In the recent Maternal Mortality Report of New York[2] the high rate of toxæmia is mentioned, and stress is laid on the assumption that the vast majority of deaths from this cause were preventable by medical supervision early in pregnancy. Of 251 patients that died of eclampsia only 63 were regarded as not preventable; 45 per cent. of the infants were stillborn. The highest incidence was amongst negresses who had less supervision and suffered from malnutrition.

Munro Kerr[3] gives the rate in Scotland from hyperemesis gravidarum alone as 4·6 per cent. of the total maternal mortality in 1925–30 and states that the condition is on the increase. In England and Wales this same condition was responsible for 1·7 per cent. of the total maternal death-rate for a similar length of time. Munro Kerr states that there has been no decline in the maternal death-rate from causes such as pre-eclampsia, eclampsia, and chronic nephritis. In the Glasgow Maternity Hospital, toxæmia is responsible for 25·3 per cent. of the total maternal mortality.

MATERNAL MORBIDITY

There is no means of arriving at a comprehensive or general estimate of the end-results of toxæmia of pregnancy. The follow-up researches of various clinics give ample proof of the far-reaching effects of this condition and the disablement from which women suffer as the result of childbearing. We have only to mention renal disease as an example. The chronic ill-health of women who have borne children is a commentary upon the state of our knowledge of the field of obstetrics, and is a responsibility not always recognised by public service authorities who have the care of the health and nutrition of the poorer classes. Something will have to be done about it. We achieve much when we point out that toxæmia is mainly a deficiency disease and make every endeavour to train the future practitioners along these lines. I need not dwell upon the loss of health or of the ultimate loss of life as the result of childbearing. This subject has been very ably dealt with by Prof. Blair-Bell,[4] my predecessor in these lectures.

---

* The Ingleby lectures for 1934, delivered at the University of Birmingham on April 26th and May 3rd. The concluding lecture will appear in a forthcoming issue.

FŒTAL AND INFANT MORTALITY

It is impossible to indicate in any way how far toxic conditions in the mother are responsible for fœtal and neonatal deaths. Until we have a system of notification of all abortions similar to that which we have of viable births, we cannot get much information regarding the cause of the enormous wastage of early fœtal life. Malnutrition of the mother obviously influences malnutrition of the fœtus. There are exceptions to this, however, as we know that badly nourished women produce healthy infants, although at the expense and often grave risk of their own well-being. Abortions, moles, dead- and stillbirths are the consequence in most cases of maternal toxæmia.

In the Royal Free Hospital, during a period of ten years, the highest cause of the stillbirth-rate was toxæmia of the mother. In the neonatal death-rate, 65 per cent. were due to prematurity, which is closely associated with malnutrition of the mother. Premature and badly nourished infants die or survive only with great difficulty. The fatal cases provide statistics for the two great causes of infant mortality in the first month of life—a mortality which still shows no sign of reduction when compared with that of the 11 months, the death-rate of which has been reduced to half in the present century.

Mellanby[5] states that the death-rate of infants for the first week of life is 23·5 per 1000 as compared with 3·3 per 1000 during the first four weeks. If dead and stillbirths are included the rate is 80 per 1000. This mortality is not being reduced and he puts diet deficiencies in the mother as an important cause.

Ætiology of Toxæmia

There are as yet no known specific toxins in pregnancy, although the manifestations are very similar to toxic poisoning from snake venom, phosphorus, &c. The main centre of attack seems to be in the liver and kidneys. A great deal of valuable time has been wasted in discussions upon the best methods of investigation of elusive toxins. We are now getting down to a more rational outlook and have concentrated upon the condition from its metabolic aspect.

The ovum no doubt is the primary ætiological factor, as without it presence there may have been few symptoms of toxæmia previously. A healthy young woman becomes pregnant, she must adapt her physiological functions to the new condition of affairs. The ovum is a newcomer—or as I like to call it, a temporary endocrine organ—and soon makes its presence felt and is insistent upon the proper recognition of the maintenance of its physiological existence. If the ovum fits into its surroundings the pregnancy becomes a harmonious one and all ends happily. The course may not be smooth just at first—for example, if morning sickness is troublesome. It is really this adjustment which is the difficulty. The maternal functions may be slow to adapt themselves to the new conditions. The lodger may make imperious demands and deplete the hostess not only of her food-supply but of her tissue nutrition. Until a settlement is established either member of the ménage may come off the loser. If the adjustment fails the ovum acts as a parasite and tends to poison its hostess by special demands upon her liver. The ovum may itself die because of the depletion of the maternal supply of nutriment. On the other hand, the maternal organism may not be in a condition to take on the responsibilities of motherhood owing to previous toxic pregnancies or to failure in excretory function. The ovum in such a case is the loser. It may die and become expelled, or it may struggle on courageously and survive as an ill-conditioned infant, which lives to swell the numbers of the unfit.

THEORIES

The theories as to the ætiology of the toxæmias of pregnancy are very numerous and possibly all have some element of truth. The want of balance between the ovum and the maternal organism leads to a want of balance in the endocrine organs. These glands, especially the pituitary, owing to their secretions and their influence upon reproductive functions play a very great part in maintaining the harmonious relationships between the ovum and the maternal organism. What this exact function may be is not fully known, but our research workers are gradually building up valuable evidence for clinical use. The failure of the placenta to prevent the transmission of toxic substances from or to the ovum plays a considerable part in the toxæmia. Infarctions and other pathological or autolytic changes involving loss of function or separations of the placenta have been shown to be present in cases of toxæmia. The liberation of protein poisons in the maternal circulation may fail to become neutralised, or the placenta may be deficient in its neutralising function by which it acts as a safeguard for the ovum. Failure on the part of the liver to detoxicate injurious substances is also a well-accepted theory. Now we are finding out that this failure in function is due mainly to maternal malnutrition and can be remedied by attention to diet. Defective excretory function as the result of intestinal stasis or chronic nephritis plays a large part in the causation and maintenance of toxæmia. Raised intra-abdominal pressure in the latter third of pregnancy is also a factor. The activity of the trophoblast and blood-borne fragments of chorionic villi are given as a cause in the toxæmia of early pregnancy.

Not only are errors and deficiencies of diet of significance, but over-feeding, by causing embarrassment of the digestive and excretory functions, has to be kept in mind. The influence of nervous and mental changes upon the metabolism is most important. All these factors go to make up the complexities of pregnancy. A harmonious state of equilibrium of the maternal organs and of the embryo in most cases will ensure a normal condition during gestation.

PREDISPOSING CAUSES OF TOXÆMIA

By due attention to these we may avert the onset of an attack or modify its incidence.

Age and parity.—Toxæmia of the hepatic type occurs more frequently in primigravidæ. Of 65 cases in the Royal Free Hospital 57 were primigravidæ, 8 being multiparæ—i.e., a ratio approximately of 7 to 1. In 30 cases of eclampsia the ratio of primigravidæ to multiparæ was 4 to 1. Age does not seem to have a marked influence, although one expects the condition to occur in older women whose tissues react less favourably to the changes associated with pregnancy. Elderly primigravidæ are attacked, but I have seen eclampsia occur in a girl of 14½ years. In multiparæ the renal type is more likely to occur, especially in older women having had frequent pregnancies. Twins also have a predisposing influence upon the incidence of toxæmia.

Season has little or no influence in my experience of cases. Women living in town surroundings with deficient fresh air and sunlight are much more likely to have toxæmia than women in rural areas. This may account for some of the high incidence of eclampsia in Glasgow.

Disease.—Previous attacks of scarlet fever, diphtheria, rheumatism, and other toxic conditions tend to predispose to the renal type of toxæmia. Intestinal stasis is an important factor which in its turn may be due to pituitary functional defects, want of exercise, and vitamin deficiency.

Condition of ureters.—Pressure upon the ureters attended with dilatation of the renal pelvis is associated with urinary infections of the colon bacillus type. This bacillary infection is found in a considerable number of cases and may influence the onset of toxæmia. Pyelitis is sometimes associated with vomiting. It rather tends to be a sequela of toxæmia as it appears more frequently during the puerperium than in the antenatal period. Due care should always be taken in regard to the aseptic catheterisation of toxæmic patients.

Dietetic Factors

The recent work of Harding and van Wyck [6] on sodium chloride as a factor in the causation of toxæmia is of interest, as these authorities have directed their attention to the dietetic factor in the toxæmias of later pregnancy. They do not think that toxæmia is produced by diets rich in protein or fat. Ketosis will not produce nausea or vomiting in pregnancy. These authors point out the dangers, when protein is withheld from the food, of the consequent drain on the patient's own tissues, and give the result of interesting investigations upon the sodium base in sodium chloride or salt intake. If salt is freely given in the diet of a normal pregnant patient its effects are negligible; if, however, there is a tendency to toxæmia, the condition is intensified. They conclude that salt is the dietetic factor in the production of the toxæmias of later pregnancy. When hypertonic saline was given to normal pregnant patients, in one case, diarrhœa occurred, and headaches and gastro-intestinal disturbancss in another. They found that in cases of mild toxæmia there was increased albumin and hypertension together with vomiting, headaches, and epigastric pain. Thus the intake of salt resulted in the intensification of the toxic symptoms. When salt was withdrawn the toxæmia showed marked diminution. Salt also caused retention of fluid in the tissues and consequent œdema. Sweating and venesection are beneficial because of the lowering of the salt content in the tissues. Harding and van Wyck advise glucose solution as a substitute for saline transfusion.

Weight changes in toxæmia.—A considerable amount of recent research has been carried out by Davis,[7] Harding and van Wyck, and Bingham and others upon the significance of an undue increase of weight in pregnancy. This work throws a new light not only upon the prophylaxis of toxæmia but upon its ætiology. A large or sudden increase in weight in the latter part of pregnancy is very signficant of water retention in the tissues. It is, therefore, an earlier clinical sign than œdema. The normal gain in pregnancy should be not greater than 20 lb. (9 k.) except in the case of under-nourished women who have reacted to treatment. Bingham gives this gain at 16 lb. In the first three months there is little gain in weight. Primigravidæ gain less than multiparæ. Heavy women gain more than light, especially towards the later weeks of pregnancy. If the gain is excessive it is due to "occult œdema" and is associated with the sodium chloride intake. It is accompanied not infrequently by albumin in the urine and suggests the presence of toxæmia and of nephritis.

Regulation of diet.—The diet must be regulated and, if necessary, cut down in amount considerably. It is pointed out that at antenatal examinations the routine weighing of patients should be carried out as it is just as important as testing for albumin in the urine. Scales should be in the necessary equipment of every antenatal clinic. Harding and van Wyck point out that the coarsening in features which some women acquire in pregnancy is due to excessive food intake and fluid retention. This disappears after delivery. Stout women should not be allowed to gain more than 2 lb. a month in pregnancy. If this "latent dropsy" is recognised in time following the danger signal of sudden gain in weight, much of the consequences of renal dysfunction will be avoided. It is said that the diminution in eclampsia in Central Europe during the war was not due to a diminished protein intake alone but to reduction in diet as a whole. Bingham, on investigating a series of cases which had excessive monthly gains in weight, found that nearly all his cases of toxæmia were confined to this group. An increase in weight preceded the rise in blood pressure and the appearance of albumin.

As a result of these investigations I have instituted weighing machines in our clinics and the patients are weighed at each visit. In the short time of observation I have seen the value of weight-taking as a gauge of the condition of the patient. When the patient is advised to take exercise in the open air such as a two- or three-mile walk daily up to near the end of pregnancy, the benefit to the ordinary patient is remarkable. She becomes much more cheerful and her gain in weight remains normal. Patients suffering from cardiac or renal complications are, of course, not included in this treatment.

Classification

It is better to wipe out all the intricacies of the textbook labels and start afresh in view of our present-day knowledge of the varieties of toxæmia. Why should hyperemesis gravidarum be given the first position in our books? Is it because of its gravity or because the term is loosely used to denote the vomiting of pregnancy in the early months? Excessive vomiting is a very rare condition in pregnancy, and yet the student is taught to consider it as one of prime importance in obstetrics which may necessitate the termination of pregnancy. Surely this point of view is out of date. There are many cases of vomiting in early pregnancy which are amenable to medical treatment and do not require obstetrical interference. Discussions are rife in regard to the position of the degenerative areas in the hepatic lobules—a central area may indicate one form and a peripheral another form of toxæmia. Does this really matter? We do all we can to prevent our patients reaching the post-mortem room and make our diagnosis at the bedside with the valuable help of the clinical pathologist. The toxæmias of pregnancy with our present knowledge cannot be put into pigeon-holes. It is more than likely that there is very little difference between the various forms except that of degree: the peculiar manifestations depend to a great extent upon the individual patients who are concerned. Symptoms naturally vary in their onset, association, and gravity, and the same form of toxæmia in early pregnancy may be manifested in one case by severe vomiting, whereas in another individual it may show itself later as eclampsia or acute yellow atrophy. As far as we go at present, we can only divide the types into two main groups: (1) hepatic, and (2) renal. It may be that in the future we shall have information at our disposal which will enable us to classify the toxæmias in more detail with special reference to pituitary and other endocrine dysfunction.

HEPATIC TOXÆMIA

In the hepatic type the patient has been as a rule healthy before the onset of pregnancy and the toxic condition is due to failure on the part of the liver *to adjust itself to the new conditions on account of* deficiencies of certain substances which are necessary for its function and which are being withheld from the mother or drained away by the ovum for its own nutriment. This type is often acute, such as the fulminating form of eclampsia, acute yellow atrophy or the severe vomiting of early pregnancy. It is of short duration and may end fatally; if recovery does take place it is usually complete. There may, however, be some renal damage which becomes manifest during a subsequent pregnancy. This type is due in the majority of cases to deficiencies in diet or over-feeding.

The liver *is concerned* with the neutralisation of protein substances, and most investigators believe that if so-called toxins—which we might now call *x* or the unknown quantity—are found they will be of the protein variety. When the liver cells are destroyed by toxic substances, neutralising substances in sufficient amount, such as glucose and calcium, being withheld, the result is a severe condition of toxæmia. The tests for liver function are so varied and controversial that, as clinicians, we have still to rely upon our own observations for a due appreciation of the gravity of the condition. Jaundice with bile in the urine is a marked danger signal in cases of toxæmia. It may not be as delicate a test for the onset of liver damage as certain laboratory tests, but it is of value for clinical purposes. Some take the nitrogen partition of the blood and the excess of urobilin in the urine as a method of diagnosis of hepatic toxæmia. Globulin is said by some to be found in greater quantity than that which occurs in the toxæmia of renal origin. This *theory is queried* by Cruickshank.[8] Acidosis is closely associated with hepatic toxæmia. The loss of fœtal life is less marked in a hepatic toxæmia as the fœtus is, so to speak, the parasite which drains or poisons its mother. In the renal type the maternal tissues fail to convey sufficient nutriment to the fœtus, and the latter may die at any stage of its existence.

TOXÆMIA OF RENAL ORIGIN

Much has been written on this subject by such investigators as Kellog,[9] Young,[10] Gibberd,[11] Browne and Dodds,[12] Stander and Peckham,[13 14] Evans,[15] and Munro Kerr.[3] In the discussion of the subject at a meeting of the Obstetrical Section of the Royal Society of Medicine in November, 1933,[16] I pointed out the importance of the renal factor, and this point was discussed at greater length by Osman [17] and by Bright Banister [18] at the same meeting.

There is difficulty in the diagnosis of the condition in pregnancy and *often it is only on following up* the patients for some months or years after a pregnancy complicated with toxæmia that the extent of the renal damage can be estimated. There are two main types of renal damage. There is the type in which the kidney function seems to recover and remains healthy so long as the patient is not exposed to a subsequent pregnancy. If pregnancy which has been called the "acid test of renal function" occurs in these cases, there may be kidney breakdown which simulates toxæmia of the hepatic variety. Some confusion has been caused regarding the name which is to be applied to this type. It has been called the kidney of pregnancy, occult nephritis, low reserve kidney or lowered renal threshold, recurrent toxæmia (Kellog), and albuminuria of pregnancy. I think perhaps the simplest denomination is that of Stander and Peckham—low reserve kidney. The condition is that of an intermittent nephritis or nephrosis without any definite inflammatory changes. It often clears *up after the pregnancy is over unless the symptoms* have been severe or there have been repeated subsequent pregnancies, when it merges into the chronic nephritis type.

In the section on Nephritis complicating Pregnancy of the New York City Report [2] on Maternal Mortality and Morbidity, 1933, it is stated that it is often impossible to tell clinically the extent of the kidney damage. Stander and Peckham's [13] classification is referred as (*a*) chronic nephritis complicating pregnancy, (*b*) eclampsia and nephritis, and (*c*) low reserve kidney. The report refers to the last type as the Nephritis Toxæmia of pregnancy. The history before and after pregnancy is perhaps clinically the only method available for the diagnosis between the toxæmia of pregnancy and chronic nephritis. If the symptoms occur early in pregnancy the condition is more likely to be the nephritic type. Stander lays stress upon the urea and creatinin tests as an aid to diagnosis. If the urea clearance is below 80 per cent. of the normal and the creatinin excretion below 155 mg. in the first hour, renal damage is present. Previous chronic nephritis with pregnancy superadded is a definite renal lesion due to previous scarlet fever, diphtheria or other toxic disease, and where renal breakdown occurs early in pregnancy.

In the books on nephritis, among which one may mention that of MacLean,[19] I find very little stress placed upon childbirth as a cause of chronic nephritis. Few physicians dwell upon it and yet, from the obstetrician's point of view it is a very serious sequela of pregnancy. Gibberd,[11] especially in several publications of his research upon the follow-up of cases, *points to the gravity of the condition. Osman* [17] is one of the few physicians who seems to emphasise the necessity for investigating the history of previous pregnancies when dealing with cases of nephritis; he discusses at some length the presence of hypertension and oliguria following toxæmias of pregnancy. All observers upon the late results of this condition refer to the subsequent health disability involved as well as the fatal endings after several years. Young [10] found that when he followed up 91 cases of toxæmia, good health was observed in 58·3 per cent. of these, impaired or poor health in 41·7 per cent. Stander found in the Johns Hopkins Hospital that 42 per cent. of patients die of chronic nephritis within five years. Gibberd found in 41 cases of toxæmia that recovery was complete. When the next pregnancy occurred, albumin was found in 59 per cent. of the cases. He therefore advises induction of labour in all cases of toxæmia if albumin persists for three weeks, there being grave danger of permanent kidney damage if pregnancy is allowed to continue. Cruickshank refers to the advance attained in our knowledge of Bright's disease by the realisation that extrarenal factors play a much more important part in the pathogenesis and symptomatology than was previously supposed. He lays little stress upon the influence of pregnancy but mentions that the toxæmias of pregnancy cause renal degenerative changes which constitute a mixture of nephritis and nephrosis. Cruickshank gives over-eating as a factor in the causation of Bright's disease.

Miss Rodway, in the Obstetrical Unit *attached to* he Royal Free Hospital, followed up 50 cases of oxæmia and found the following results :—

There were 34 *primiparæ.*—None of these had any history of previous renal complications. Eighteen had good health, 2 showed chronic nephritis, 9 had raised blood pressure without albuminuria, and 1 had raised blood pressure with albuminuria. There were 4 with headaches and giddiness, but these did not have albuminuria or a raised blood pressure.

There were 16 *multiparæ.*—Seven of these had no history of renal complications at previous pregnancies. Of these 1 had good health, 2 had albuminuria (? chronic nephritis), 2 had raised blood pressure without albuminuria, and 2 had headaches. Nine cases had a history of previous renal complications. Of these 3 had chronic nephritis and 6 had raised blood pressure and general debility but no albuminuria.

TOXÆMIA AND THE TOXÆMIA OF PREGNANCY ASSOCIATED WITH RENAL DAMAGE

It is important not to confine attention to eclampsia alone in dealing with cases of toxæmia but to keep in mind the possibilities of late renal dysfunction, a condition the evidence of which in many cases may be suppressed until a subsequent pregnancy takes place.

Renal damage is a serious complication of pregnancy and becomes more so as subsequent pregnancies occur. The damage to fœtal life is also a consequence of renal damage in the mother. It is difficult to make a differential diagnosis between toxæmia of pregnancy and nephritis, and most clinicians agree that the diagnosis in some cases may have to be deferred until after-results of childbirth have been investigated. It must be remembered that renal damage may follow toxæmia. If the symptoms begin early in pregnancy, if they are insidious in onset, never reaching an acute stage, if childbirth is followed by ill-health, the condition is probably due to serious renal damage.

The following points may be of some use as a general guide :—

	TOXÆMIA	RENAL DAMAGE
Age ..	.. Younger women ..	Older.
Parity	.. Primigravidæ ..	Multiparæ.
Previous history.	Good health ..	Scarlet fever, diphtheria previous pregnancy toxæmia.
Onset	.. Late pregnancy, sometimes sudden.	Early pregnancy, insidious.
Abortion	.. Not usual	Frequent.
B.P. ..	.. Varies, very high sometimes but not prolonged.	High and prolonged, sometimes no other sign.
Eyes	.. Few changes	Retinitis.
Jaundice	.. Serious sign	Rarely present.
Urine	.. Diminished quantity. High sp. gr. Albumin copious.	Increased quantity. Albumin. Low sp. gr. Casts.
Blood	.. N.P.N. Lower post-partum. Urea lower than in pregnancy.	Higher post-partum than in pregnancy. Urea higher.
After-effects..	Rare unless subsequent pregnancies.	Almost constant.
Convulsions ..	Eclampsia in severe cases.	Uræmic convulsions.

Toxæmia as a Deficiency Disease

The recent investigations of Maxwell,[20] Mellanby, Lucy Wills,[21] Green Armytage,[22] Theobald,[23] and others have completely changed our ideas upon the causation of toxæmia. We are now working upon much more rational lines than hitherto, and the results of due attention to diet deficiencies will go far to reduce the incidence of toxæmia and moderate all its attendant ills.

In the present lecture I point out the demands of the fœtus and the means of supply at the disposal of the maternal organs. In the next lecture I shall refer to the actual methods of dieting when discussing symptoms and their treatment. As a means of illustrating my remarks I should like, if it will not bore too much, to mention my method of teaching students on this subject. I take as an example the needs of the fœtus. The fœtus goes out to buy its provisions at the retail or placental shop which is in its turn supplied from the wholesale or maternal store. What does the fœtus go out to buy ? It demands all the substances which are essential for the maintenance of its normal physiological growth and function. We know something of a number of these substances, such as calcium, and the carbohydrates. Others such as the protein supply still require investigation. The maternal store gives of its reserve supplies and keeps up its stock by constant food intake. If this intake is deficient for the fœtus the supply can still be provided by drawing upon the maternal tissues. If the latter are too much drained however, a serious condition of toxæmia will ensue. If the supply fails the fœtus dies from starvation. But one's clinical experience shows that the mother's welfare is inclined in most cases to be sacrificed to the maintenance of the well-being of her fœtus. It must also be remembered that the placental " shop " may be inadequately equipped or inefficiently managed. Failure of infiltration may take place and harmful substances may not be eliminated or the nutritive supplies may not be delivered.

Calcium together with phosphorus is a very necessary element in fœtal growth, more especially in the latter half of pregnancy when the bony tissues are increasing in bulk. The fœtal blood is of higher calcium content than the maternal, and the figure for the latter is lower in pregnancy than in the non-pregnant state. Stander gives 3·3 mg. per cent. as the normal blood calcium content in pregnancy as contrasted with the non-pregnant content of 10·2 mg. per cent. Theobald refers to the storage in the bones as the maternal " deposit account " and to that in the blood and soft tissues as the " current account." 1·6 g. of calcium is required daily in pregnancy. The fœtus retains 8 g. of calcium during the last four weeks of pregnancy, and Theobald is of the opinion that the diet is insufficient for this supply. If the calcium content of the mother is low, or if she is suffering from vitamin-D deficiency, she will possibly have signs of dental caries or pyorrhœa. In eastern countries osteomalacia may be in evidence. If the fœtus, therefore, does not get its supply from the mother's food it will endeavour to get its calcium from her tissues. If the placenta is inefficient the fœtus may be denied all its nutritive demands and may die. Deficient calcium and vitamins will cause fœtal rickets, maldevelopment of the teeth, and may produce sleeplessness and muscular cramp in the mother. Restlessness on the part of the fœtus is sometimes due to the same cause.

Calcium is eliminated by the urine and fæces. Some years ago I carried out some observations upon the calcium content of menstrual fluid and found that the figure for the menstrual was considerably higher than that for the systemic blood. I also estimated the total intake and excretion of calcium in oöphorectimised animals and found that there was more retention of calcium in these animals than in the normal. It is possible, therefore, that ovarian activity may be in abeyance in pregnancy in order partly to preserve the supply of calcium which is so much needed by the fœtus.

Glycogen is essential for the nutrition of the fœtus and for storage in its liver. The maternal liver may become depleted by the fœtal requirements and acidosis in the mother will be the result. Carbohydrates mainly in the form of glycogen are stored to a greater extent in the fœtal liver than in the adult.

The placental blood-supply *obtains its glycogen from* the maternal liver and passes it on to the fœtus. Although the mother may be deficient in glycogen the fœtus still demands its supply and will insist upon it at the expense of the maternal tissues. The *maternal liver when depleted fails in its function*, the alkalinity of the blood is lowered, and acidosis is the result. The mother suffers from sickness and this in its turn aggravates the deficiency. An adequate supply for the mother is kept up by feeding her with barley sugar and other carbohydrates.

Iron is essential for fœtal nutrition and blood formation. Storage of iron and copper takes place in the liver as nature's precaution against a faulty supply in the milk-feeding period of postnatal life. Shortage of iron and other minerals will cause anæmia of the mother, which sometimes is profound. Premature babies are frequently short of iron.

Manganese and *magnesium* are also essentials.

Iodine is necessary. Mellanby and Theobald point out the advantages to be gained by a diet with enhanced iodine content as the average food has a low iodine content. It may be necessary in most cases of maternal deficiencies to supplement the diet by giving these mineral substances directly to the mother. For this reason special methods of treatment are carried out which will be referred to later. *Vitamins are essential for the proper assimilation of* the various mineral commodities demanded by the fœtus. The diet supply of the mother may also require supplementing by cod-liver oil and other substances. It has to be pointed out although these *deficiencies on the part of the maternal supply and* the consequent depletion of her tissues may lead to toxæmia and malnutrition of the fœtus, we must remember that toxæmia may also be caused by excessive supply and that results of overfeeding may be *just as dangerous as deficiencies of diet.*

Mellanby points out that vitamin A is concerned with growth and is stored in the fœtal liver, and that if supply is defective the mother suffers from infective conditions. Vitamin-B deficiency is concerned with *abortion and death of the fœtus and vitamin C also* is associated with dead births. Vitamin D is essential for the absorption of mineral substances such as calcium. The diet of the mother will be discussed later.

Death of the fœtus occurs *if any interference takes* place with the supply or transport of its nutritive necessities. A deficiency in the essentials of diet in the mother with the malnutrition which follows from the draining of her tissues by the fœtus may cause fœtal death. *Also defects in the delivery of foodstuffs* by defects in the placenta owing to degenerative changes or separation and failure in function are all contributory factors towards fœtal death. Abortion may occur from definite known causes, but in the majority of cases which we are asked to treat the cause is unknown. In recurrent abortion administration of corpus luteum and thyroid extract or Antuitrin S in many cases will carry on a pregnancy to term. Dr. Pillman Williams has published an interesting report on the results of the investigation of a number of cases of recurrent abortion sent for treatment to the Royal Free Hospital. She examined the blood of these patients *in regard to sugar tolerance* and the urine for sugar leak.

Ninety per cent. of the patients showed a lower tolerance for glucose. When the carbohydrate diet was spaced by means of smaller and more frequent meals—30 g. three-hourly—*total per diem 150–200 g.* —the result was a successful termination of the pregnancy. Dr. Pillman Williams[24] states that a very considerable percentage of cases are related not to any failure of nitrogen metabolism but to gross *errors in carbohydrate metabolism*, a fact which is not sufficiently appreciated. These patients did not leak sugar on ordinary diet. Their fasting blood-sugars were either normal or only very moderately raised. She considers that the underlying cause of the lowered tolerance for glucose is related to a lack of balance of the ductless glands. Insulin was administered in a few cases with good results.

LYMPHADENOID TISSUE OF THE UPPER RESPIRATORY TRACT

BY HENRY VINCENT FORSTER, M.C., M.B.,
M.Sc. Liverp.

HON. LARYNGOLOGIST TO THE LIVERPOOL ROYAL INFIRMARY;
HON. LECTURER IN LARYNGOLOGY IN THE UNIVERSITY OF LIVERPOOL

THE lymphadenoid tissue at the threshold of the upper respiratory and food passages has been the object of so much surgical interference that the unsolved problem of its physiology may cause anxiety to those who are called upon to perform operations for extirpation of specialised parts of the lympho-epithelial system in this area. These specialised groups are the faucial and the respiratory tonsils.

Recently there appears to have been a greater tendency to examine the subject critically. Such an impression is gained, for example, from Kaiser's book,[1] from the paper by Glover and Joyce Wilson,[2] *from the published monograph by Layton*[3] and a later paper, and from the report of the chief medical officer of the Ministry of Health for 1931[4]; and the tonsil problem as it concerns the *faucial organ* was the subject chosen by Prof. Kahler for the Semon lecture of the University of London in November, 1932.[5] Since then a further article by Layton has appeared,[6] and Heiberg [7] has published the answers to his circular questionnaire on tonsillectomy results.

The anatomy of the faucial tonsil has been many times accurately described, and its general appearance is familiar to the practitioner from daily routine examination. Superficially, this may seem to be an advantage, but this ease of access has probably led not only medical practitioners but also lay people to speculate on its pathological significance, and its tantalising proximity may have led to its being charged with offences for which it is not altogether responsible.[*]

The respiratory tonsil is differently placed. It can be studied in situ in the living by the expert in posterior rhinoscopy, and sometimes by anterior rhinoscopy, but its direct examination with the finger should be reserved for the generally anæsthetised. This inaccessibility may not be a disadvantage. In spite of the harm which an untreated respiratory tonsil may cause, I have learnt to modify my enthusiasm against it. I have never been able to feel a similar resentment against the palatine or faucial tonsils. I find it difficult to agree with the recommendation that when a general anæsthetic is given for removal of adenoids the palatine tonsils should also be sacrificed as a matter of routine. Some years ago this dissociation was appreciated in a book by Kerr Love,[8] and he repeats the idea more recently.[9] The fact that it has been advisable, in a few cases, to remove tonsils at a second operation does not justify the sacrifice of an apparently innocent tonsil at an adenoid operation.

The development of the palatine tonsils in the fœtus has been clearly described by Losanow,[10] and that of the respiratory tonsil by W. E. Cooke [11]; but the so-called germ centres or secondary follicles are not seen in either the palatine or the respiratory tonsils until after birth, or, in other words, until the infant is exposed to the infections of the outside world. It is to these germ centres (though such centres are not confined to tonsillar lymphadenoid tissue) that considerable attention has been paid by such observers as Heiberg [12] and Hellman. Neither type of tonsil is a superficial lymphatic gland in the general sense. The palatine tonsil, once thought to possess afferent lymph vessels, has been shown by Amersbach and Schlemmer not to possess them. Its lymphatic capillary system drains centripetally only, and is otherwise a closed system.

Other groups of lymphadenoid tissue may assume considerable size in different parts of the mucosa of the pharynx; such masses are often to be seen on the post-pharyngeal wall after the tonsils (faucial tonsils) and adenoids (respiratory tonsil) have been removed, although the granules from which they have arisen may previously have been invisible to the naked eye. Though similar in most respects, and both showing crypts or folds, the palatine and faucial tonsils differ in their covering epithelium, particularly as seen in the crypts. In the respiratory tonsil this epithelium is ciliated. In the palatine tonsil, mucous glands are never seen to open into the crypts, which are normally emptied by the movements of deglutition at the faucial pillars; whereas in the respiratory tonsil mucous glands open into the depths of the crypts, pouring out secretion which cleanses them and provides mucus to cover the surface of the organ. This is emphasised by Pierce Sturm,[13] and is well shown in the microphotographs of Cooke [11] and C. F. Hill.

THE FUNCTION OF THE LYMPHADENOID TISSUE OF THE PHARYNX

If we go back as far as 1880 we find the idea, now rejected, that the faucial tonsils were concerned somehow with digestion. Some have considered them to be almost useless—a view with which we cannot now agree; others have suggested that they give architectural finish to the faucial arches and perhaps act as pulleys to the musculature of the anterior and posterior pillars. These mechanical ideas are reasonably sound, but there is growing recognition that these organs, in conjunction with the other lymphadenoid tissue in the pharynx, are concerned with protection against microbic invasion.

In the germ centres, which he calls secondary follicles, Hellmann observes a reaction to invasion. Heiberg finds lymphocytes to be destroyed in this site—not produced, as Fleming thought; and Viggo Schmidt,[14] studying the immunising properties of leucocytes, postulates the formation of endolysins in the destruction process. Waldapfel and Grossmann, of Vienna,[15] described the histopathology of tonsils removed during acute tonsillitis, and found polymorphonuclear leucocytes with intracellular cocci in the germ centres; normally, neither are to be found in the lymph follicle. These observers point out that acute tonsillitis, though appearing in several clinical forms, is not a catarrhal infection but a disease of the tonsil as a whole. The phlegmonous appearance is an outstanding feature of the pathological picture; the pharyngeal tonsil may behave in a similar way, or may not be involved in the process at the same time. They believe that their findings confirm Hellman's idea of the lymphatic tissue acting as a protective wall against bacterial and toxic products invading the organism.

An endocrine function was attributed to the tonsils by Voss, who thought they retarded growth; but as Albrecht and Kahler point out, later work failed to support this. Halasz,[16] experimenting with rabbits, has tried, more recently, to revive this idea, but Reichmann [17] finds himself unable to support it.

Yoffey,[18] discussing the lymphocytes, says :—

> "It is quite likely that the lymphocytes are concerned with the active growth processes of childhood and that the lymphoid tissues act as a storehouse of primitive wandering mesenchyme cells to supply the various tissues as they are needed."

This recalls the view expressed by Syk [19] that the lymphocyte [18] is capable of wandering into the pharyngeal lining tissue and performing the nutrition-bearing function of the threpocyte of Carrel [20]; Schmidt found that the number of lymphocytes in the peripheral blood count could be influenced by massaging the tonsils. Finally, Halasz claims that he can relieve attacks of pharyngitis in individuals whose tonsils have been removed (pharyngitis tonsillopriva of Pollatschec), or in old people whose lymphadenoid tissue has atrophied, by injections of albumin-free tonsil extract.

In considering the functions of the lymphadenoid tissue of the upper respiratory tract Barnes [21] has warned us against flights of scientific imagination which are difficult to refute; but the subject is surrounded with difficulties. Schmidt recalls that, at a discussion on the tonsil problem at Kessingen in May, 1923, the debate came to an end with the statement of Schlemmer's hypothesis: The lymphatic

---

[*] Kaiser states that : "During the last 15 years the frequency of tonsillectomy has greatly increased. It became a matter of common occurrence to have a parent or neighbour rather than the physician decide whether the tonsils should be removed."

tissue forms an integrant part of the pharyngeal tissue without any separate functions.

CHRONIC TONSILLITIS

When suspicion gathers around the faucial tonsils as a possible source of local or general disease what local evidence can be collected against them? Hypertrophy is by no means evidence of disease in itself. It may, however, give rise to mechanical inconvenience even to the extent of marring speech, interfering with breathing or swallowing, or preventing proper ventilation of the Eustachian orifices by hypertrophy extending into the soft palate. If these sequelæ can be proved to have occurred then the tonsil is mechanically pathological. Some tonsils are so much pedunculated as to appear enlarged and are then frequently, though unjustifiably, condemned on sight. A condition of hypertrophy may be in itself a measure of functional ability, but a condition of great hypertrophy may become a pathological state, in so far as the organ becomes liable to acute attacks of inflammation. Heiberg,[12] calling attention to the process of so-called necrobiosis in the germ centres, saw the possibility of the process being carried to excess, with increase in size of the organ and lengthening of the crypts—a vicious circle leading to vulnerability and disease. Hypertrophy in excess, therefore, may become a pathological state apart from mechanical considerations. Marked diminution in size may also point to a pathological state; it may mean fibrosis, the result of past infections, a greater proportional diminution of the lymphoid tissue and loss of function. Halasz regards this as a state of negative allergy; but it may also be looked upon as the neutral state described in Schmidt's experiments on tonsil massage.

The plica supratonsillaris and the plica pretonsillaris may be sources of embarrassment to a tonsil, causing a sort of phimosis at the outlets of their respective recesses; and Kahler draws attention to the transverse bar or plica of Grünwald. The tonsillar recesses may become sites of stagnation, and therefore the starting points of invasion. We know that we can relieve patients from localised inflammation and save them from immediate tonsillectomy by gently releasing detritus from the pretonsillar recess. It has even been suggested that circumcision of this plica pretonsillaris might be practised. Fibrous scars of the tonsil surface indicate past inflammation, but should not be confused with the plica transversus which appears to divide the tonsil into an upper and lower part.

Much attention has been given to the presence of crypt material as evidence of chronic disease, and in the small proportion of cases where it consists of actual pus—laden with a higher percentage of leucocytes—disease can certainly be diagnosed. Crypt material or tonsil detritus, as a rule, however, may be no more harmful than the epithelial collections to be found under the finger-nail. Such collections should not be confused with the horny plugs of tonsillar keratosis. To reach agreement on the healthy or pathological state of a tonsil is a delicate matter, and tonsillar keratosis may lead to the severance of *diplomatic* relations with a colleague who may not have attempted to remove those surprisingly adherent horny particles.

Berggren and Hellman[22] have published an elaborate paper of their research on chronic tonsillitis.† They quote Hajek's remark that "the most certain proof of a chronic tonsillitis is always the occurrence *of repeated acute attacks.*" Berggren and Hellman conclude that "chronic tonsillitis with free intervals" is nothing but the frequent recurrence of inflammatory attacks in tonsils whose physiological capacity has been subjected to severe strain. Even the first attack of acute angina therefore may be the real starting point of a chronic process, which may show little in the way of definite clinical signs or symptoms in the tonsil itself, but may form the basis of a general infective condition.
